"Effort" Thrombophlebitis.—Lenormant and Mondor recognize that thrombophlebitis may appear spontaneously in normal individuals, who attribute this condition, rightly or wrongly, to traumatism or effort. Many instances are cited in the literature—at least fifty are conditions of traumatic or effort phlebitis of the upper limbs, most often the right upper limb. The authors review two personal observations; the first is a clinical history, the second is more complete and convincing since surgical intervention made possible a histobacteriologic examination of the vein and the clot. It is their belief that thrombophlebitis is an infectious disease due to bacteria lodged in the wall of the vein or in the clot; that the influence of effort or traumatism in the appearance of thrombophlebitis is indirectly minimal; that in that case the condition is latent thrombophlebitis of infectious origin revealed by effort or traumatism indirectly; and that "effort" phlebitis should be added to "effort" orchitis among the list of disease entities that are actually not demonstrated and very probably imaginary. Treatment in the majority of cases of thrombophlebitis includes rest, compress dressings, elevation of the limb; and the patient improves more or less slowly with more or less important sequelae and hardly ever emboli. Surgical intervention usually consists in the resection of the thrombosed vein between two ligatures. However, the small number of such interventions reported in the literature does not permit a definite conclusion at present.

Asthma and Fever.—Bezançon and Jacquelin found that febrile infections may sometimes cause the appearance or reappearance of asthmatic attacks with fever so high that the conditions are often mistaken for capillary bronchitis or bronchopneumonia. It is difficult to explain the mechanism in which an acute infection leads to sedation of more or less serious and prolonged asthma. Fever can both produce asthma and arrest it. This power is vested in general acute infections without distinct localization (influenza, a seasonal infection, septicemia, eruptive fever), sudden infections (tuberculosis), localized nonsuppurative infection (appendicitis), suppurative infections (tonsillar or peripharyngeal phlegmon, abscess of lymph node, lung abscess, suppurative osteomyelitis of tibia, furuncle, anthrax). The efficacy of the liver is completely independent of the cause that produces it. These febrile states are all accompanied by intense polymorphonucleosis. During the fever the authors recommend a very reduced dietary regimen, no chlorides, plenty of fluids, juices of fruits and vegetables, also rest in bed, and prescription of cholagogues and laxatives. The aim should be to counteract the intoxication during the fever and diminish the asthmatogenous autointoxication resulting from fatigue, dietary abuse, and hepatic deficiency. During asthmatic attacks the alkali reserve is increased and the p_H of the blood is decreased. Fever interrupts asthmatic attacks when it prevents the displacement of the acid-base balance toward the alkaline side. Asthma is characterized by an increase in mononuclear leukocytes and eosinophils and a decrease in polymorphonuclear leukocytes. Favorable medications should produce leukocytosis with polymorphonucleosis: injections of epinephrine, peptone, vaccines, phlyctenotherapy, and ultraviolet irradiation in strong doses. Induced hyperthermia works in the same manner as spontaneous hyperthermia. Pyretotherapy is especially indicated in asthma with subintrant crises as well as conditions of permanent dyspnea caused by asthma. The authors consider the use of massive doses of ultraviolet rays with induced temperature of from 38 to 38.5 C. for from twenty-four to forty-eight hours; subcutaneous injections of autovaccines, stock lysate vaccines and antichancroid vaccines with single doses not smaller than two billion organisms injected at intervals of two or three days as contraindicated. Intravenous injections of antichancroid vaccines are most easily regulated; however, a fixation abscess (from 1 to 2 cc. of oil of turpentine injected subcutaneously) although painful is also efficient. The recurrent asthmatic attacks after treatment are not so severe and are then more easily treated with epinephrine or ephedrine.

Ether Narcosis by Rectum. E. Fermaud.—p. 1711.

Roentgen Irradiation of Suprarenal Region in Treatment of Diabetes.—Langeron and his co-workers do not believe that their researches during the last two years warrant definite conclusions; however, their impressions of the results obtained seem worthy of note. They describe the results obtained in eleven patients under observation and conclude that in diabetes of moderate intensity one can obtain through roentgen irradiation of the suprarenal region and without inconvenience interesting abatement in the glycosuria; in severe diabetes with acidosis, on the contrary, the results are negative and the method is distinctly contraindicated. The results obtained in the first series are sufficiently interesting to favor treatment. Only diabetes is considered in this report, arterial symptoms and trophic disturbances having been considered in other articles. The results in roentgen therapy are equivalent to those obtained after denervation of the suprarenals.

So-Called Malignant Nephrosclerosis (Fahr).—Patrassi discusses, on the basis of seven cases of renal sclerosis (in most of which death had resulted from renal insufficiency), the conception of malignant renal sclerosis in its morphologic and pathogenic characters. The fundamental change in the small arteries consisted of arteriosclerosis with hyaline degeneration of the walls. No true necrosis or fibrinoid degeneration of the arterial walls was encountered. Even in case of ischemic infarct of the kidney the necrosed arteries did not show a special affinity for fibrin (Weiggert method). With respect to intensity and course the lesions of the arterioles and of the glomeruli did not always run parallel. The latter, especially when subjected to excessive work (as in compensatory hypertrophy), may become primarily involved. Of great importance for the genesis of the tubular changes are the thickening and the hyalinization of the basal membrane of the tubules. These changes, from a pathogenic and functional point of view, are comparable to those of the basal membrane of glomerular loops.

Research to Identify Cancrigenic Agent of Coal Tar.—Lazzarini searched in the white mouse for the cancrigenic substance of tar. The first research deals with the black granulations that are commonly observed in the internal organs of mice whose skin has been tarred. The microchemical researches produced uncertain results. The second research refers to phenols and to the pyridic bases extracted from the internal organs of the mouse by means of distillation in a jet of steam; the results furnish negative evidence for the action of these substances. The third research is made on pyrolic and indolic compounds; the author succeeded in demonstrating an oncogenic action of these substances in three ways: (1) finding of indole and pyrol in the internal organs of mice treated with tarring of the skin; (2) provoking cancer in mice treated with parenteral injections of indole and pyrol and not thoroughly tarred, and (3) ascertaining that in animals treated only with injections of indole and pyrol, changes similar to those that are to be observed in mice simply tarred appear in the internal organs. Having thus demonstrated the cancrigenic action of indole and pyrol, the author adds that, even if these substances possessed a cancrigenic action, it alone would not be sufficient to provoke a cutaneous cancer but would require other adjuvant forces, which are to be sought not only in other components of tar but also in special individual and ambient conditions. The author, in conclusion, formulates tar complex (C), plus organism complex (O), plus stimulus factor (S), as the probable pathogenesis of the cutaneous tar cancer, assigning to the first group (C) the compounds of the pyrolic and indolic group; to the second group (O) the defense reaction of the tissues and allergic defense, and to the third group (S) the inflammations.

Vaginal Route in Surgery of Tumors of Internal Female Genital Organs. A. Chueco.—p. 1749.
Cortical Hepatitis Causing Hepatic Colic. R. Solé.—p. 1757.
*Mean Blood Pressure in Goiter. E. B. del Castillo and A. F. Nanclares.—p. 1766.
Circumscribed Forms of Tuberculosis of the Bones. M. J. Fitte.—p. 1773.
Semeiologic Interpretation of Teleroentgenograms of "Middle Arc." P. Cossio, R. Dassen, R. Lottero Lanari and I. Berconsky.—p. 1786.

Mean Blood Pressure in Goiter.—Castillo and Nanclares made oscillometric determinations of the mean blood pressure in twenty-eight persons with several forms of goiter, with and without hyperthyroidism. The first group (goiter patients with hyperthyroidism) included fourteen patients with toxic adenoma and seven patients with exophthalmic goiter. The second group (goiter patients without hyperthyroidism) included seven patients with nontoxic adenoma. The author concludes: The mean blood pressure is increased in 44 per cent of patients with toxic adenoma and is normal in 56 per cent. There is a relative increase of the mean blood pressure in patients with exophthalmic goiter. The mean blood pressure is normal in patients with nontoxic adenoma.

Treatment of Hyperthyroidism by Intravenous Injections of Sodium Fluoride.—Goldemberg states that animal experimentation has proved that fluorides retard development and produce the same results as if the young animal were thyroidectomized. One milligram of thyroxine in solution is precipitated by 0.01 Gm. of sodium fluoride, immediately on or after several minutes of contact. The logical next step is the administration of sodium fluoride in human hyperthyroidism. The author describes the good results obtained in twenty days with daily doses of from 40 to 60 drops of a 2 per cent aqueous solution of sodium fluoride, given by mouth in the first patient treated by the new method. However, intolerance to buccal medication in subsequent patients imposed the use of tentative intravenous injections beginning with 1 cc. of a 0.5 per cent aqueous solution, later changed to 1 per cent, then to 2 per cent and at last to the optimum of 2.5 per cent; the dose increasing to 5 cc., 10 cc., 25 cc. and even 35 cc. without any bodily intolerance or bad effect on the veins used for the injections. When the intravenous dose of fluoride is higher than 0.1 Gm. per injection, irrespective of the titer of the solution in use, patients complain, within ten minutes after the injection, of pain and cramps in the lumbar region or in the abdomen, lasting from five to ten minutes. Extravasation of some drops of the fluoride solution into the cellular tissue will produce local pain, burning and swelling which disappear in a few hours without leaving any local necrosis. Doses higher than 0.1 Gm. of fluoride or several daily injections will react with a polyuria of 4 or 5 liters of urine daily, intense thirst, nycturia and pollakiuria, but never with albuminuria and glycosuria. These symptoms disappear two or three days after suspension of the treatment. Therapeutic action of the fluoride is slow and progressive. The nervous symptoms disappear first, sleep returns, tachycardia diminishes and the palpitations vanish. The patient gains in weight, the basal metabolism becomes practically normal, the thyroidal swelling goes down and the exophthalmos, although not disappearing completely, is greatly reduced. The author uses a solution of 2.5 Gm. of pure sodium fluoride in 100 cc. of distilled water; the solution is filtered, put in 5 cc. ampules and sterilized in the autoclave. Injections are started with 3 cc. of this solution, gradually increased to 6 cc. and maintained until improvement sets in, then decreased to 4 cc. and continued until a series of from fifteen to twenty injections have been given. In the beginning, depending on the seriousness of the condition, injections are administered every day or every other day and later, when justified by the improvement, every three or every four days; from then on the series of injections alternate with rest and the whole treatment runs its course in from five to ten months. It is advisable to institute two or three series of injections annually during the subsequent two or three years. If treatment by mouth is desired to alternate with the injections, the solution is made with 2 Gm. of sodium fluoride or ammonium fluoride in 100 cc. of distilled water, and from 10 to 50 drops in milk are given four times a day during a period of fifteen to twenty days. In other words, the dosage increases steadily from 40 to 200 drops a day. Treatment by sodium fluoride may also be given to prepare the patient for surgical intervention in case of voluminous goiter and when the patient is in no condition to stand a protracted medical treatment.

Treatment of Asphyxia in the New-Born by Means of Carbon Dioxide Gas Mixtures.—Wiener first discusses the various means and methods that are employed in the treatment of asphyxia in the new-born and in severe dyspnea in the new-born and in nurslings. Particular attention is given to carbon dioxide gas mixtures, which in recent times have found a wide application. Further, the author relates his experiences with carbon dioxide gas mixtures in twelve cases of asphyxia in the new-born, in twenty-three cases of severe dyspnea during the first days of life, in six cases of respiratory disorders and collapse in nutritional disturbances, and in seventeen cases of diseases of the air passages and of the lungs. On the basis of these observations he considers the use of carbon dioxide air mixtures and of carbon dioxide oxygen mixtures as that method, which in asphyxia of the new-born, as well as in dyspneic conditions of the new-born and of nurslings, is always applicable and in the majority of cases accomplishes its purpose.

Syndrome Observable in Commotio or Contusio Cerebri.—Mann emphasizes that the detection of the general postcommotional syndrome is not sufficient, but that efforts should be made to detect certain groups of symptoms which indicate a definite cerebral localization. He admits that it is not entirely correct to designate such localized cerebral symptoms as signs of a commotio cerebri, for they are rather foci of contusion. However, it should be considered that between "commotio" and "contusio" there is only a quantitative difference. If the injurious force that strikes one portion of the brain is especially severe, a contusion is the result with its visible and permanent anatomic changes. Such symptoms of contusion may occasionally develop entirely without or with only slight commotional manifestations, but in the majority of cases the symptoms of contusion at first concur with those of commotio. The author then describes the syndrome that he observed most frequently in traumas of the brain. The symptoms are the following: 1. There is difficulty in directing the eyes to one side, while they can be readily directed to the other. 2. When the patient stands with closed eyes a swaying toward the same side is noted on which the visual direction is impaired. 3. In the past-pointing test a deviation to the same side is noted. 4. Frequently there is a unilateral absence of the normal oscillations of the arms during walking. 5. The hearing capacity is impaired on the side corresponding to the side with the impaired visual direction. 6. The reflexes of the cornea and of the nasal mucous membrane are reduced on the same side. 7. In addition to these local symptoms there are also generalized symptoms such as general vasomotor hypersensitivity, with acceleration of the pulse and a rushing of the blood to the head, and in some of the cases the pressure of the cerebrospinal fluid is increased. If all these symptoms are considered as a whole it can be seen that they are essentially coordination disturbances, and since the coordinatory functions are controlled mostly by the cerebellum and its tracts, the author assumes that the syndrome is characteristic for cerebellar disturbances or at least for the disturbances of the posterior cranial fossa. He goes even further in his attempts to localize the injury producing the described syndrome, by citing facts that indicate localization in the corpus restiforme.

Intramuscular Injection of Blood in Diseases of the Respiratory Tract.—Bals states that in recent years hemotherapy has found wider application in pediatrics. Interlobar exudates, which are often refractory to most therapeutic measures, were found to yield to intramuscular injection of blood. In chronic febrile diseases of the respiratory tract this form of hemotherapy proved likewise effective. The author recommends for such cases the intramuscular injection of small quantities (from 20 to 60 cc.) of whole blood. Of course, she does not wish to discredit intravenous blood transfusion, but she points out that intramuscular injection is more practical, since it makes preparatory serologic tests superfluous and also because its technic is simpler. Moreover, the small amounts of blood that are required are usually readily obtainable. Injurious effects of blood injections are unknown, and the resorption is usually rapid. Long periods of fever can often be shortened, and the disease can be cured more quickly by this form of hemotherapy. For this reason, intramuscular injection of blood should always be given a trial.

Endocardial Fibrosis of Young Nursling.—Becker observed indurated fibrosis in the left cardiac ventricle in a nursling, aged 3 months. She considers this endocardial fibrosis as the thrombogenic type for she assumes a causal relationship between the thrombophlebitis of the right leg, to which the mother was subject during pregnancy, and the endocardial fibrosis in the infant.

Acetarsone in Treatment of Congenital Syphilis.—Nedelmann maintains that acetarsone is the best substance for the treatment of syphilis in early childhood. Years of experience convinced him that acetarsone should not be given in several small series of treatments, but if possible should be completed in one series with sufficiently large doses. He confirms the roborant action of acetarsone but warns against the use of the preparation in nonsyphilitic conditions. For cases of hypersusceptibility to acetarsone he recommends intramuscular injections of a liver extract. He also reports investigations on the elimination of arsenic in the feces and in the urine of children treated with acetarsone.

Qualities of Fat Metabolism Hormone of Anterior Lobe of Hypophysis.—In the introduction Anselmino and Hoffmann call attention to the three principal actions of the anterior hypophysis, namely, its influence on growth, on the generative glands, particularly the ovaries, and on the fat metabolism. Disturbances in the fat metabolism, as observed in adiposogenital dystrophy or after extirpation of the anterior hypophysis, had led several authorities to assume a hypophyseal action on the fat metabolism, but it remained for the authors to detect, prepare and study the qualities of the hormone. After citing factors that indicate the existence of a hypophyseal hormone effective on the fat metabolism, they describe its preparation from the anterior hypophysis of beeves. The increase of the acetone body content of the blood of rats, to which that extract has been administered, is the test method for the hormone. With the aid of this test the authors determined also the chemical and physical qualities of the metabolic hormone, which are largely identical with the known qualities of the genitally active component of the anterior hypophysis. But in spite of this the metabolic hormone differs from the genitally active component. Factors are cited that establish the identity of the demonstrable acetone body increasing substance with the metabolic hormone. For the standardization of the hormone the authors recommend the rat unit and give its quantitative definition.

Effects of Fat Metabolism Hormone of Anterior Lobe of Hypophysis.—Hoffmann and Anselmino describe various metabolic and regulatory effects of the metabolic hormone of the anterior lobe of the hypophysis. Administered in sufficiently large doses to rats and also to human beings, the metabolic hormone effects acetone body formation, especially beta-oxybutyric acid formation, also a decrease in the basal metabolism and an increase in the specific dynamic action. The hormone is discharged when fat is burned in the organism. This regulatory significance of the metabolic hormone for fat combustion can be demonstrated in fat tolerance tests on human beings and in starvation tests on dogs. Finally the authors call attention to the significance of the metabolic hormone for a number of problems in normal and pathologic physiology.

Systolic Blood Pressure in Older Persons.—A review of the literature convinced May that the opinion prevails that in older persons the blood pressure is higher. He maintains, however, that clinical observations do not corroborate this. Tests on 518 persons, some of whom had circulatory disorders and some of whom did not, revealed that the "normal" (he prefers the term "rest blood pressure") is between 100 and

145 mm. of mercury in all age groups. The apparently contradictory results of former tests he explains as the result of a greater lability of the blood pressure in not resting persons beyond the age of 40 years. The question is discussed whether these blood pressure fluctuations may not be the precursor of the transitory and also of the fixed hypertensions.

Pathologic Significance of Bleeding Mamma.—Pribram shows that hemorrhage into the mamma usually takes place into preformed cysts. If such a cyst communicates with the main discharging duct, blood is discharged by the mammilla. But the discharge of blood is no indication of a malignant tumor. On the contrary, hemorrhages are a rarity in closed cancer of the mamma. The most common cause of hemorrhage of the mamma is an intracanalicular hemorrhagic cystepithelioma, a small tumor, which is regularly located in a cystic enlargement of one of the larger lactiferous ducts. This tumor takes a median position between benign and malignant growths, but it shows no tendency to relapse and metastasize. During long years of observation the author never observed a relapse, in spite of the fact that he never performed a radical amputation with removal of the lymph nodes but always confined himself to the extirpation of the mamma. This conservative surgical attitude seems the more justified because the majority of the patients were young women and usually the cyst formation was bilateral. However, it is necessary to keep such women under constant medical observation.

Orifice of Ureter and Bladder Contraction.—In this paper Israel reports his studies on (1) the behavior of the ureteral orifice during the contraction of the bladder, and (2) the causes of an eventual closing. In regard to the first problem he states that experiments on dogs, in which vesical contractions were produced by faradic stimulation of the pelvic nerve, indicate that during vesical contraction, at least during the largest portion of its duration, the ureteral orifice remains closed and urine does not enter the bladder. This interval of time is termed the "micturition pause of the ureteral orifice." Thus the animal experiments corroborate the cystoscopic observations that Boeminghaus made on human beings during the voluntary evacuation of the bladder. To the second problem the author remarks that experiments on the open bladder prove that the increase of the intravesical pressure during contraction and thus the active valve mechanism of the relaxed bladder do not play an important part in development of the micturition pause. Experiments on ureters recently implanted into the bladder prove that the omission of the urinary spurts of the ureteral ostium during the contraction of the bladder is dependent neither on the normal distal termination of the ureter nor on muscular or nervous connections between bladder and ureter. The essential cause of the omission of the urinary spurts of the ureteral ostium during vesical contraction is the compression of the distal termination of the ureter by the surrounding vesical muscles. The significance of the ureteral closing during contraction of the detrusor lies not in the development of the pause in micturition of the ureteral ostium but in the prevention of the ureteral reflux.

Function of Upper Urinary Passages Following Implantation of Ureter into Bladder.—This report brings the continuation of the studies described in the preceding article. Israel discussing the problem whether the closure produced by the muscular contraction is sufficient to prevent reflux without the other devices. In the summary he states that the prevailing opinion that atony and reflux are necessary sequelae of resection and reimplantation of the ureter are erroneous. Observations on dogs that were killed eleven and twelve months after the operation indicate the possibility of a permanent effectiveness of the implantation. Experiments prove that in dogs the ostium can be secured against reflux without resorting to the oblique passage of the ureter through the vesicular wall and without depending on the valvular closure produced by that procedure. Indispensable and alone sufficient to secure the upper urinary passages against reflux are (1) in the bladder that is filling or relaxed, the capacity of the ureter to contract sufficiently; (2) during contraction of the bladder the compression of the vesical termination of the ureter by the vesical muscles. These two factors that secure the newly formed ostium explain, according to their efficacy or inefficacy, the following conditions: (*a*) cases in which following implantation of the ureter into the bladder, the upper urinary passages retain their normal function; (*b*) cases in which reflux develops on the distal termination of the ureter following its implantation or after other operations; (*c*) numerous cases of spontaneously developing reflux; (*d*) the rare cases of cure of reflux by implantation of the ureter into the bladder.

Abscess Formation in Salivary Glands of the New-Born.—Since former reports on this comparatively rare condition contain little about its pathogenesis, Kriss reports his investigations on this problem. Following the report of the clinical history of two cases he gives a general discussion of the clinical aspects and states that the therapy should follow general surgical principles. In regard to the bacteriologic conditions it is stated that staphylococci were found in the two reported cases and a number of other authorities observed the same; however, others observed streptococci, diplococci, Monilia albicans or a mixed bacterial flora. In a study of the pathogenesis of inflammation of the salivary glands in infants it is of course necessary to differentiate between the isolated inflammation of these glands and the inflammation as a partial manifestation of a generalized sepsis. The author discusses only the first form, for which there are two possibilities of pathogenesis, namely, a hematogenic and an ascending infection from the oral cavity. On the basis of his investigations he concludes that the isolated inflammation of the salivary glands is caused in the majority of cases by the ascent of pathogenic organisms from the oral cavity and invasion into the glands. For this mode of pathogenesis two factors are essential, namely, (1) the presence of pathogenic micro-organisms in the oral cavity of the new-born and (2) a factor that creates a predisposition. Investigations on the bacteriologic conditions in the oral cavity of the new-born revealed that shortly after birth the saliva is usually sterile but tests on nurslings between the first and eighth day of life revealed the presence of micro-organisms that can be considered pathogenic. In regard to the predisposing factors it is pointed out that in forceps deliveries the region of the parotid may be injured, and it is also emphasized that parotitis is especially frequent in premature infants, that is, in infants with lowered resistance against infections. Other predisposing factors may be high degree of virulence of the salivary bacteria, abnormalities in the excretory ducts of the glands and faulty sucking on the part of the child.

Lochia After Cesarean Operations.—Bardenheuer observed that after cesarean operations the lochia is surprisingly scanty and the involution of the uterus is more rapid than after normal delivery. As cause of this he considers the acidosis, which is produced by the postoperative starvation, for hunger, thirst and wound healing processes cause acidosis. He concludes that in normal puerperas the lochia could be reduced by giving for about eight days a diet like the one Herrmannsdorfer recommended for the treatment of wounds. This diet eliminates milk, potatoes, sausages, and most fruits and vegetables; the fluid intake is limited and seasoning with salt is avoided. Recommended are meat, fish, eggs, butter, lard, bread, foods prepared from flour, cheese, brussels sprouts, lentils, nuts, cranberries, lemon juice, cocoa, tea, coffee and honey. The fat intake should be high, but carbohydrates should be reduced.

Gas Analysis of Cerebrospinal Fluid in Nervous Diseases.—Kulkov and Tarnopolskaya as a result of their studies conclude that the carbon dioxide (alkali reserve) of the spinal fluid differs in disease. The largest determination for carbon dioxide of the spinal fluid (alkalosis) was found in dementia paralytica and epilepsy and one instance of alcoholism. Severe acidosis (decreased carbon dioxide) was found in various forms of meningitis, namely in toxemic forms, diffuse infection of the brain, encephalitis, diffuse sclerosis and symptomatic epilepsy. Determinations were normal in tumors of the brain and spinal cord and in tabes dorsalis. There was no greater tendency toward alkalosis in cerebrospinal syphilis. The relationship between carbon dioxide and other substances as globulins and chlorides was not studied. The authors noted an increase in carbon dioxide in tabetic atrophy of the optic nerves at the same time that other forms of tabes dorsalis gave normal carbon dioxide determinations.

Dry Pleurisy in Acute Rheumatic Infections of Children.—Shteinberg and Kopeliovich, in their examination of eighty-two children with rheumatism, diagnosed dry pleurisy and pericarditis in thirty-eight: nine patients with pleurisy and pericarditis, twenty-six with pleurisy alone, and one with pericarditis alone. They conclude that in the course of acute rheumatism one may also find a concomitant infection of dry pleuritis which runs its own clinical course. The presence of infection of the serous membrane is a frequent symptom of rheumatism. Dry pleurisy has a practical significance in the clinical prognosis of rheumatism (polyarthritis, chorea, carditis). Dry pleurisy may be the primary or the only symptom in rheumatic infection. In the course of the ambulatory forms of rheumatic endocarditis the condition may simulate the clinical picture of tuberculous intoxication. The relation of dry pleurisy of rheumatism to tuberculosis necessitates further study.

Some Considerations on Epilepsy. V. M. Faybushevich.—p. 1596.

New Method of Treatment Using Antidiphtheritic Serum.—Yarotskiy believes the high mortality in diphtheria is unwarranted. It is possible to bring the mortality down to 0.4 per cent. He believes that smaller doses than 10,000 antitoxic units should not be used and in severe conditions this dose should be repeated within the same day and repeated in the following days until toxic symptoms disappear or become minimal. During treatment no days should pass without an injection of serum. The author describes his results in the treatment of 248 patients with various types of diphtheria. Horse serum was used throughout. The injections were performed intramuscularly.

Large Doses of Serum in Treatment of Toxic Diphtheria.—Volovik asserts that massive dosage in serum therapy is highly effective in uncomplicated toxic forms of diphtheria. In moderately severe forms, final injection of doses of from 100 to 125 thousand antitoxic units of serum decreased the mortality from 16 per cent to zero; in very severe forms, injection of doses of from 200 to 300 thousand units of serum with an initial dose of 100 thousand antitoxic units decreased the mortality from 69 to 30 per cent. However, in hemorrhagic forms, large doses of serum did not bring about similar remarkable recoveries—mortality was decreased from 88 to 64 or 65 per cent. This may be explained by the premature presence of cardiac disturbance.

Abortion Without Sufficient Hospitalization.—Anufriev asserts that in the proceedings of the convention of obstetricians and gynecologists at Kiev in 1927-1928 it was decided that abortion was not an inconsequential surgical intervention and therefore could not be performed without hospitalization. It was reported that after the intervention there is a change in the reaction of the vaginal secretion and at the third day there is a microbic flora in the uterus (staphylococcus or bacilli) that indicates infection. It was decided that postoperative supervision should be continued for at least three weeks after abortion. Most postoperative disturbances occur in the endometrium: incomplete regeneration and the presence of necrotic tissue open the road to infection. Abortion was considered an important factor in the decrease of subsequent pregnancies in young women. It was decided that the medical profession should insist on hospitalization of patients during and after surgical abortion.

Sense of Vibration in Neuralgias. F. Bro.—p. 1031.

Intracranial Aneurysm in Girl Aged Six Years.—Necropsy disclosed that the sudden death without preceding illness in the case described by Ortmann was due to an extensive subarachnoid hemorrhage from the rupture of a sacculated aneurysm of the right anterior cerebral artery. Microscopically a distinct defect was seen in the media of the artery at the seat of the aneurysm. The author is inclined to believe that an embolic process during the child's grave diphtheria at the age of 3 had led to the formation of the aneurysm at this already weak place in the arterial system.

PNEUMOCOCCUS TYPE II PNEUMONIA

A CLINICAL AND BACTERIOLOGIC STUDY OF ONE THOUSAND CASES, WITH ESPECIAL REFERENCE TO SERUM THERAPY *

RUSSELL L. CECIL, M.D.
AND
NORMAN PLUMMER, M.D.
NEW YORK

In a previous article, we [1] have analyzed 1,161 cases of pneumococcus type I pneumonia treated in the wards of Bellevue Hospital, and have pointed out the beneficial effect of serum therapy in this type of infection. In the present article, we propose to discuss pneumococcus type II pneumonia and to report our results in the treatment of this disease with specific antipneumococcus serum. This investigation comprises 1,000 cases of type II pneumonia from the wards of Bellevue Hospital, and covers a consecutive series except for the year 1925-1926, which is not included because the records for that winter are incomplete. So far as we know, this is the first clinical study ever published in which pneumococcus type II pneumonia is considered as a separate entity. In 1927, Baldwin and Rhoades [2] contributed an article on the specific therapy of type II pneumonia, in which they discussed the effect of type II antipneumococcus serum on twelve cases, but there has been no detailed presentation of this type of pneumonia as a clinical entity.

BACTERIOLOGIC METHODS

From 1920 to 1929, the mouse method of typing sputum described by Avery, Chickering, Cole and Dochez [3] was employed as a routine. The objection to this method lay in the amount of time it involved. On the average, reports were not obtained in less than from eighteen to twenty-four hours, which meant serious delay in the institution of serum treatment. Since 1929, a combination of the original mouse method and the Krumwiede [4] and Sabin [5] methods of typing has been employed, and this procedure has enabled the laboratory worker to report the pneumococcus type on a high percentage of cases within from one to five hours. The actual routine is as follows:

> The best specimen of sputum obtainable is sent to the laboratory as soon as the diagnosis of pneumonia has been made. A portion about the size of a bean is emulsified in physiologic solution of sodium chloride and from 0.5 to 1 cc. of this is injected into the peritoneal cavity of a mouse. The remainder of the sputum is typed by the Krumwiede method.[4] If the test gives a positive reading, it is usually accurate. If it is negative or unsatisfactory, the Sabin [5] microscopic method of typing is used by withdrawing a few drops of peritoneal exudate from the mouse and carrying out the agglutination reactions on a glass slide. If neither the Krumwiede nor the Sabin method gives positive reactions, the original mouse method of tube-agglutination and precipitation is performed in full.
>
> If no sputum is available, a generous swab is made from the posterior pharynx and transferred to a tube of broth, which is allowed to incubate for two hours at a temperature of 37 C. One cubic centimeter of this culture is then injected into the peritoneum of a mouse, and microscopic or macroscopic typing is performed as previously outlined. Sputum, of course, is preferable, but the swab method, if properly carried out, gives accurate results. All readings, by whatever method obtained, are confirmed by typing the cultures obtained from the heart's blood of the mouse.

During the past three years, blood cultures were performed on all patients with lobar pneumonia shortly after their admission, and these were repeated daily on patients whose first blood culture was positive, and also on all patients who failed to improve under treatment. The usual procedure was to withdraw 3 cc. of blood from the patient's vein and add 1 cc. to a tube of broth and 1 cc. to each of two pour plates.

Routine cultures were also made from all pleural, pericardial and synovial exudates.

Accuracy of the Combination Method of Typing.—During the season of 1929-1930, specimens of sputum from 196 patients with lobar pneumonia were typed by the rapid methods. Fifty-eight of the 196 cases proved to be pneumococcus type II infections, as checked by cultures from the mouse's heart's blood. Of these fifty-eight cases, twenty-eight provided enough tenacious sputum to be tested by the Krumwiede method, and twenty-five of the twenty-eight gave a sharply positive reaction. In other words, 43 per cent of authenticated type II pneumonias were accurately typed by the Krumwiede method, and in fifty-two of the fifty-eight cases, or 90 per cent of the type II series, positive results were obtained with either the Krumwiede or the Sabin method. Thus, by using one or the other of these rapid methods of typing, 90 per cent of the fifty-eight type II pneumonias were accurately typed in less than five hours, and 43 per cent were successfully typed by the Krumwiede method in less than one hour. The Krumwiede method gave no false readings; the Sabin method only two.

INCIDENCE

Of the various types of lobar pneumonia, pneumococcus type II ranks second in frequency, being exceeded only by the type I group. Table 1 indicates the relative incidence of the dominant types. In an analysis of 4,310 pneumococcal pneumonias, type I infections were most frequent, comprising 32.1 per cent of the whole series; type II came second with an incidence of 23 per cent, almost a fourth of the series; type III made up only 11.1 per cent. Group IV, which includes a large number of infrequent types, comprised 33.8 per cent. These figures, of course, apply to Bellevue Hospital only, but they agree fairly well with those of other institutions. For example, Avery, Chickering, Cole and Dochez[3] report an incidence of 29.3 per cent of type II pneumonia in a series of cases from the Hospital of the Rockefeller Institute, while Park, Bullowa and Rosenblüth[6] found a considerably lower incidence, only 15.6 per cent of type II infections in a series of 793 cases studied at the Harlem Hospital.

Table 1.—*Incidence of Pneumococcus Types in Lobar Pneumonia, Bellevue Hospital, 1920-1931* *

Pneumococcus	Number of Cases	Percentage of Incidence
Type I	1,384	32.1
Type II	991	23.0
Type III	477	11.1
Group IV	1,458	33.8
Total	4,310	

* 1925-1926 cases are omitted from this series.

Incidence of Type II Pneumonia in Children.—In a series of 329 cases of pneumonia in children at Bellevue Hospital (recently reported by Raia, Plummer and Schultz),[7] only 9 proved to be of type II origin. Three of these occurred in children under 3 years of age, the remaining six in children between 3 and 12 years of age.

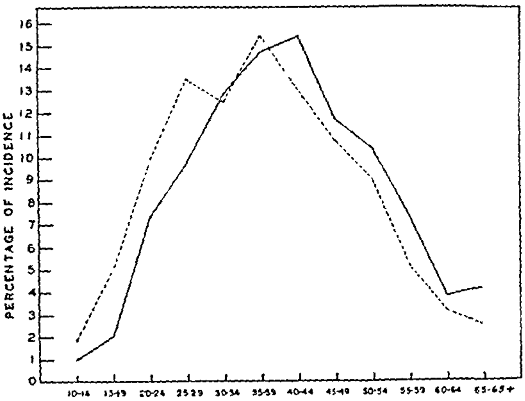

Chart 1.—Age distribution of type I and type II pneumonia, Bellevue Hospital, 1920-1931: solid line, type II pneumonia; broken line, type I pneumonia.

Incidence According to Age.—The age incidence of type II pneumonia corresponds fairly closely with that of type I. In reporting our previous studies,[8] we stated that pneumococcus type I pneumonia was particularly common in young people. This is true also of type II infection, but the difference in age distribution is not as striking as we had anticipated. Thirty per cent of our type I cases occurred in patients under 30 years of age; only 20 per cent of the type II series came within this age limit. This difference is offset by a slightly higher incidence of type II pneumonia in patients between the ages of 30 and 50, and also in those above 50. In table 2 the incidence, according to the various decades, is compared and this is shown graphically in chart 1. From this table the inference can justly be drawn that both type I and type II pneumonia occur chiefly in persons who are still leading active lives and are exposed frequently to contact infections.

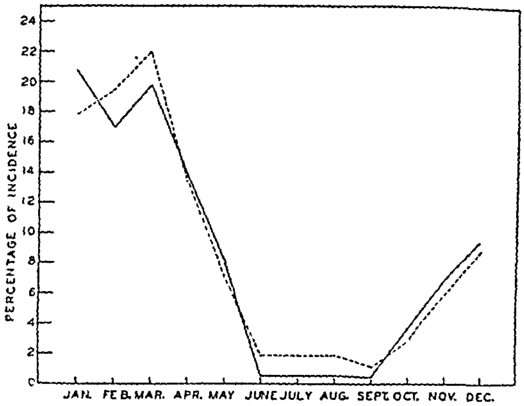

Chart 2.—Seasonal distribution of type I and type II pneumonia, Bellevue Hospital, 1920-1931: solid line, type II pneumonia; broken line, type I pneumonia.

In chart 2 the incidence by month of pneumococcus type II pneumonia is compared with that of type I infection. Here, the two types are more closely parallel. For both types the highest incidence is in January, February and March, and the lowest, during the summer months.

Table 2.—*Incidence of Type I and Type II Pneumonia According to Age, Bellevue Hospital, 1920-1931* *

Age	Type I Cases	Incidence, per Cent	Type II Cases	Incidence, per Cent
10-19	94	6.8	30	3.1
20-29	325	23.6	165	16.8
30-39	387	28.0	271	27.6
40-49	298	21.6	266	27.1
50-59	195	14.1	174	17.7
60 and over	81	5.9	76	7.7
Total	1,380		982	

* 1925-1926 cases are omitted from this series.

CLINICAL FEATURES

In our analysis of pneumococcus type I pneumonia, we spoke of type I pneumonia as a typical form of the disease. The same statement applies to the type II infection. Cole,[9] in his De Lamar lecture, states that type I pneumonia and type II pneumonia should be considered specific infectious diseases, just as typhoid is recognized as a specific infection. We are completely in harmony with this point of view. In our experience, it has not been possible to distinguish type I from type II pneumonia clinically, though perhaps it is safe to say that patients with type II infection tend to be more toxic and that their sputum is more prone to be markedly rusty and tenacious.

[9] Cole, R. I.: Acute Pulmonary Infections, De Lamar Lectures, 1927-1928, Baltimore, Williams & Wilkins Company, 1928.

COMPLICATIONS

The incidence of complications in type II pneumonia varies but slightly from that in type I, except in respect to empyema, which occurs about half as frequently in the former as in the latter group. This is shown not only in the table of clinical complications (table 3) but also in the table of complications listed from autopsy observations (table 4). In Locke's study of 478 cases of empyema,[10] the preponderance of pneumococcus type I complications in the pleura is much more marked than in our own series. He found that in forty-nine cases of empyema 48.4 per cent yielded pneumococcus type I, while only 5.2 per cent were of type II origin.

It is interesting to note, as shown in table 4, that pneumococcus endocarditis occurred twice as frequently in type II as in type I pneumonia. This is probably related to the high incidence of pneumococcus bacteremia in type II pneumonia, a feature that will now be discussed.

BACTEREMIA

In a total of 202 cases in which no serum was administered, 162, or 46.4 per cent, showed type II pneumococci in the blood, yielded by culture at some time or other during the course of the disease. This is considerably higher than the figure which we obtained for type I pneumonia (29.7 per cent) and goes far to explain why type II pneumonia is such a serious infection.

TABLE 3.—*Complications in Type I and Type II Pneumonia of Adult Patients*

Complications	Type I (1,131 Cases)	Percentage of Incidence	Type II (991 Cases)	Percentage of Incidence
Empyema	73	6.5	38	3.8
Meningitis	20	1.8	24	2.4
Acute arthritis	10	0.9	5	0.5
[illegible]	7	0.6	3	0.3
[illegible]	4	0.4	12	1.2
Phlebitis	5	0.5	8	0.8
Pleurisy with effusion	26		15	
Cellulitis	32		17	
[illegible]	26		24	
	3		..	
	4		5	
	5		2	

MORTALITY RATE

Table 5 shows the annual mortality rate for type II pneumonia from 1920 to 1931. None of the patients listed in this table received serum. The annual rate varies from 38.7 to 57.2 per cent. Some of this variation, perhaps most of it, is due to the fact that the number of cases for each year is comparatively small. The total of 441 cases showed a death rate of 48.8 per cent. In other words, practically half of the type II pneumonias at Bellevue Hospital end fatally. While the result is consistent with the type of patient treated in this hospital, it is interesting to compare this death rate with that of 28.5 per cent reported by Cole[9] from the Hospital of the Rockefeller Institute, and with that of 30 per cent reported by Park, Bullowa and Rosenblüth[6] in the Harlem Hospital. Undoubtedly, the general physical condition of the patient has a great deal to do with the outcome in this as in other types of pneumonia. We have reason to believe that the high incidence of alcoholism is a factor in the high death rate at Bellevue.

Our figures show a definite relationship of bacteremia to the mortality rate in type II pneumonia. In the series that received no serum, sixty-four cases with bacteremia showed a death rate of 87.5 per cent, while seventy-one cases with sterile blood cultures yielded a death rate of only 8.5 per cent. The close relation between bacteremia and the mortality rate has been stressed in our previous studies and by other observers, but it is particularly well illustrated in pneumococcus type II infections.

TABLE 4.—*Complications in Type I and Type II Cases—Autopsies*

Complications	Type I (52 Cases)	Percentage of Incidence	Type II (79 Cases)	Percentage of Incidence
Empyema	14	26.9	9	11.4
Meningitis	6	11.5	10	12.7
Endocarditis	3	5.8	9	11.4
Suppurative pericarditis	2	3.8	2	2.5
Lung abscess	1	1.9	3	3.8
Miliary lung abscess	2	3.8	3	3.8

The death rate for type II pneumonia at Bellevue Hospital is almost twice as high as that for type I, 48.8 per cent versus 28.2 per cent. It is interesting to note how closely these figures compare with the incidence of bacteremia in these two types of pneumonia:

Type	Bacteremia Per Cent	Death Rate Per Cent
Pneumococcus type I pneumonia	29.7	28.2
Pneumococcus type II pneumonia	51.1	48.8

The mortality is not only closely related to the presence or absence of bacteremia but is also dependent in great measure on the number of organisms present in the blood stream. Three patients who received no serum showed 22, 25 and 68 colonies of type II pneumococcus in their blood culture plates but, in spite of this handicap, recovered. Except for these three cases, no patient recovered who had more than 5 type II pneumococci per cubic centimeter of blood. This statement, of course, applies only to patients who received no serum. The serum-treated patients will be discussed later.

There also appears to be some difference in the significance of early and late bacteremia. An early bacteremia, if not severe, is sometimes overcome; that developing late in the disease is practically always fatal.

TABLE 5.—*Annual Mortality Rate of Patients with Type II Pneumonia Not Receiving Serum, Bellevue Hospital*

Year	Number of Cases	Deaths	Mortality Rate
1920-1921	32	13	40.6
1921-1922	42	17	40.5
1924-1925	30	15	50.0
1926-1927	31	15	48.4
1927-1928	77	44	57.2
1928-1929	69	34	49.3
1929-1930	62	24	38.7
1930-1931	98	53	54.1
Total	441	215	48.8

The mortality rate for type II pneumonia varies, of course, with the age. Between the ages of 20 and 30 the death rate in the present series was only 22.2 per cent, while in patients over 60 the death rate was 78.5 per cent. The mortality rate was also closely related to the complications. All the patients who developed pneumococcus meningitis, endocarditis or peritonitis died. Thirty-eight patients with empyema showed a death rate of 50 per cent.

---

[10] Locke, E. A.: Acute Empyema, New England J. Med. **203**: 391-398 (Aug. 28) 1930.

SPECIFIC TREATMENT

In our recently published study of pneumococcus type I pneumonia, we reported a series of 239 cases of type I infection treated with concentrated and refined antipneumococcus serum, compared with a control series of 234 untreated cases. The death rate in the latter was 31 per cent, as compared with only 20 per cent in the serum-treated cases, and there was a still further reduction to 11.2 per cent in cases treated within seventy-two hours after onset. From experimental, clinical and statistical evidence, we concluded that type I antipneumococcus serum, when administered early and in adequate doses, usually yielded satisfactory results.

During our study of the specific treatment of type I pneumonia, we became interested in the subject of serum therapy for type II pneumonia. Since the death rate in type II infections is approximately twice that in type I, the need of some form of specific treatment is obvious. Furthermore, there is such a close bacteriologic relationship between pneumococcus type I and pneumococcus type II, and so much clinical resemblance in the infections which they produce, that a certain similarity in their response to specific serum would seem reasonable. However, certain fundamental differences between the two diseases do exist. In the first place, the very fact that type II pneumonia is such a fatal infection means that, in order to be efficacious, a serum must be administered early in the course of the disease and must be of high potency. Secondly, according to the work of Dochez and Avery,[11] there is a greater amount of soluble substance in the blood and urine of a patient with type II pneumonia than in that of a patient with a type I infection. The serum, to be efficient, must neutralize all this soluble substance and must eliminate from the blood stream the pneumococci which are usually present in severe cases. This again calls for the administration of a highly potent serum early in the disease. Attempts to meet these requirements encounter great difficulties because, although it is important to have a highly potent serum for the treatment of type II pneumonia, the serum produced by immunizing horses against pneumococcus type II is usually much lower in content of agglutinins, precipitins, and other protective bodies than a good type I serum.

In a previous article, we pointed out the experimental, clinical and statistical evidence that has been accumulated in favor of type I serum, but so far the evidence in support of type II serum is largely of a theoretical or experimental nature. Various laboratory animals can be immunized with killed cultures against pneumococcus type II infection, and mice can be uniformly saved from a fatal type II sepsis if sufficient type II serum is injected simultaneously with the culture. Cecil and Steffen[12] found that Huntoon's pneumococcus type II antibody solution possessed the faculty of sterilizing the blood in type II pneumonia in monkeys, provided the sepsis was not too severe at the time the serum was introduced. So far as clinical evidence in favor of an efficacious type II serum is concerned, there is some difference of opinion. Cole,[13] for example, treated a small series of type II pneumonias with homologous antipneumococcus serum and was quite discouraged with the results obtained. In 1917 Avery, Chickering, Cole and Dochez[3] said: "The serum of type II is much less efficacious. Indeed, it has not yet been thoroughly demonstrated whether it has any practical effect on the outcome of the disease or not." Cole's explanation of the inefficacy of type II serum was that it was not sufficiently potent. He says: "Whereas the horse serum against type I infection is of such a strength that 0.2 cc. will regularly protect a mouse against 0.1 cc. of virulent culture, it has been impossible to produce an immune type II serum of any greater activity than that 0.2 cc. will protect a mouse against 0.01 cc. of culture."

Ten years later, however, we were able to obtain from the New York City Board of Health a type II antipneumococcus serum of such potency that 0.2 cc. would protect a mouse against 0.2 cc. of virulent type II culture. In other words, the serum was twenty times as potent as that employed by Cole and his co-workers in their therapeutic experiments with type II serum. The results obtained with this serum were more encouraging than those reported by Cole and were made known in an article by Baldwin and Rhoades[2] in 1927. These writers succeeded in sterilizing the blood of a small number of patients with type II pneumonia, and, furthermore, they noted some rather striking clinical reactions in certain type II cases which they had treated early in the course of the disease.

These earlier investigations with type II antipneumococcus serum demonstrated quite clearly that if the serum were to be of any value at all it would have to be employed in a highly concentrated form. Gay and Chickering,[14] in 1915, found that by mixing immune serum with a solution of pneumococcus bodies of the same type, a precipitate was formed which contained most of the protective substance of the serum. This could be dissolved in an akaline medium and a clear solution of pneumococcus antibodies obtained. In 1921, Huntoon[15] modified this method, using the washed pneumococcus bodies, and thus produced a therapeutic agent practically free from serum protein, and fairly potent in protective substance against type I and type II pneumococcus. Felton,[16] in 1924, found that practically all the protective substance could be obtained in a precipitate formed by adding the serum to a large amount of distilled water. More recently, Felton[17] has combined the salting-out method of Avery with his own, to refine and concentrate to a further degree the pneumococcus serum for therapeutic use.

INVESTIGATION AT BELLEVUE HOSPITAL

Our first experience with the specific treatment of type II pneumonia was in 1920, when we undertook to investigate the immunologic and therapeutic properties of Huntoon's "pneumococcus antibody solution." This product was not a serum but an aqueous solution of immune bodies which had been removed from antipneumococcus serum by adding to it an excess of pneumococci and later dissociating the immune substances from the bacteria. Huntoon's antibody solution was polyvalent, but its protective power against type II was not as high as against type I. The results of our two years' experience with Huntoon's antibody solution[18] have been published in full. Eighty-three cases of type II pneumonia, admitted to six medical wards of Bellevue Hospital, were treated with antibody solution and showed a death rate of 27.7 per cent. Sixty-seven control cases, admitted to six other medical wards during the same period of time, received no specific treatment and showed a death rate of 40.3 per cent. These figures were slightly in favor of the treated group, but the series was too small to have much significance. Because of its low potency and its tendency to produce severe chills, we abandoned the use of Huntoon's antibody solution in 1922. This experiment, however, showed the desirability of obtaining some form of purified serum. Huntoon's antibody solution was practically free from horse protein, so that its administration was never followed by anaphylactic reactions or serum sickness.

FELTON'S CONCENTRATED SERUM

From 1924 to the present time, Felton's concentrated antipneumococcus serum has been used at Bellevue Hospital. The method of preparation of this serum has been described in previous articles by us and in Felton's own papers.[19] The finished product is a slightly opalescent aqueous solution, rich in pneumococcus immune bodies.

Table 6.—*Comparison of the Common Immunologic Reactions of Type II Pneumococcus Serum and Its Concentrate (Felton)*

	Serum	Concentrate
Precipitins	25–100*	200–2,000
Agglutinins	20	300
Complement fixation	20	120
Opsonins	40	320
[illegible]	5 × 10²	2 × 10⁵
[illegible]	400	3,000
[illegible]	25	300

* The figures indicate the highest dilutions giving positive reactions.
† The figures indicate the actual number of bacteria killed.

The potency of Felton's serum varies with different lots, but manufacturers overcome this difficulty by pooling the serum from several horses. The actual ratio of the potency of the concentrated to that of the unconcentrated serum has been difficult to determine, for the reason that laboratories have employed different methods of standardization. Felton,[20] however, has recently published an article in which he presents a comparison of the common immunologic reactions of unconcentrated serum with those of the concentrated product. This is shown in table 6. The concentrated type II serum was prepared from a certain lot of standard serum and then compared with the original serum in respect to its content of immune bodies. It was found to contain far more precipitins, agglutinins, opsonins and other protective substances than the original serum. The difference in protection is particularly marked and in this experiment indicates that the concentrate was about eight times as potent as the unconcentrated serum.

From 1924 to 1930 we conducted a carefully controlled therapeutic experiment with Felton's serum on patients with type II pneumonia. The alternate case method was used in our investigation; that is, every patient diagnosed as having lobar pneumonia was given a number, and those with even numbers received serum, while those with odd numbers served as controls. The method of administering the concentrated serum has been described in detail in a previous article. After a preliminary test for sensitiveness to horse serum, 5 cc. of concentrated serum was slowly injected intravenously. If no reaction occurred, from 10 to 20 cc. was introduced into the blood stream one or two hours later, the dose depending on the potency of the preparation and the severity of the case. In general, we tried to administer from 100,000 to 200,000 units (from 40 to 100 cc.) during each twenty-four hour period until the patient showed definite signs of recovery or until it was evident that the serum was exerting no influence whatever on the disease.

The effect of type II serum on the clinical course of the disease is not by any means as striking as that produced by serum in type I pneumonia. Even when patients are treated very early, a rapid drop in temperature with concomitant improvement is rarely achieved. There is, however, a definite impression among most of the clinicians who have followed type II serotherapy that the symptoms of toxemia are usually less pronounced in the treated cases.

EFFECT ON BACTEREMIA

One of the most important problems in this study was to determine the effect of type II serum on pneumococcus type II bacteremia. As has already been stated, the outcome of a case of type II pneumonia depends to a great extent on whether or not the blood remains sterile. The figures cited in the untreated cases showed a mortality rate of only 8.5 per cent when the blood cultures remained negative, as against 87.5 per cent when the patients became septic. Furthermore, only two of the patients in our entire control series whose blood contained more than 10 type II organisms per cubic centimeter recovered. With these facts in mind it seemed reasonable to assume that, if concentrated serum was potent enough to sterilize the blood, it would have a favorable effect on the outcome of the disease.

Under certain circumstances, Felton's type II serum has, without doubt, the capacity to sterilize the blood and to keep it sterile. In most of the early cases with beginning septicemia the blood culture became negative when sufficient serum was administered, and as a result the chances of recovery seemed to be greatly increased. Charts 3 and 4 show the clinical courses of two such cases. In both patients, a definite therapeutic effect was apparently achieved by the prompt administration of serum. At any rate, they show a course not taken by our control cases. Large amounts of serum will practically always sterilize the blood of even late type II cases with marked sepsis, but this accomplishment usually has no effect on the final outcome of the disease. A remarkable case in our series had innumerable colonies of type II pneumococcus in the blood on admission, as shown in a 1 cc. pour-plate culture. The blood was successfully sterilized with large amounts of serum, but empyema developed, followed by a lung abscess, and the patient died eight months later.

Chart 5 clearly shows that sepsis was more marked in the treated patients who recovered than in the controls. *Twenty-three septic patients who received serum recovered while only ten without serum got well.* The maximum number of organisms in 1 cc. of blood was 333 in the treated series; 68 in the control. Furthermore, nine of the serum treated group had more than 10 pneumococci in each cubic centimeter of blood; only two of the control group had such a quantity.

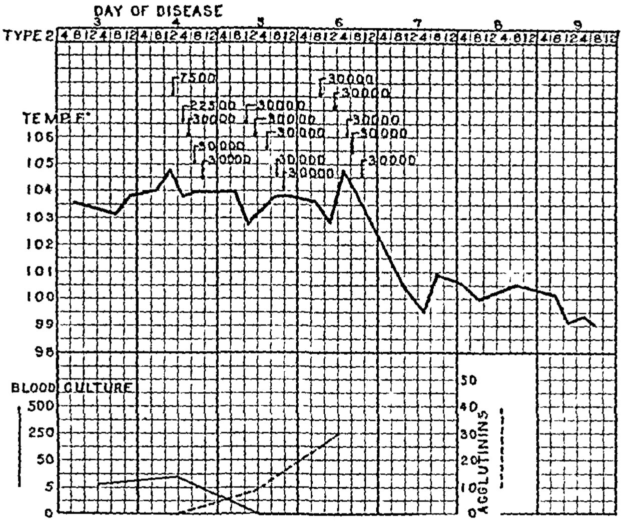

Chart 3.—Temperature, results of blood culture, and agglutinin titer of F. H., aged 26, with type II pneumococcus pneumonia, admitted to Bellevue Hospital on the third day of his illness. The blood culture on the day of admission showed 8 type II pneumococci per cubic centimeter of blood, and on the next day, the fourth day of the patient's illness, 22 organisms. On that day, 80 cc. (120,000 units) of Felton's concentrated serum was given intravenously, and the following day the blood was sterile with a moderate amount of type II agglutinins. On the fifth and sixth days, serum therapy was continued (100 cc., 150,000 units each day). The blood remained sterile, the agglutinins rose rapidly, and the patient had a temperature crisis on the seventh day.

Since 1928, blood cultures have been taken as a routine on all patients included in the type II series. In the septic cases the mortality rate for the control group has been 88 per cent; for the treated group, 69 per cent. The capacity on the part of type II serum to prevent bacteremia is further shown by the fact that, while 91 per cent of the untreated patients who died had positive blood cultures, 74 per cent of the treated died with bacteremia.

Table 7.—*Comparison of Mortality Rate in Cases Treated with Felton's Concentrated Serum and Control Cases**

* Patients dying within twenty-four hours are not included.

EFFECT OF TYPE II SERUM ON MORTALITY RATE

The effect of concentrated type II serum on the mortality rate of type II pneumonia is indicated by the year in table 7. Altogether 252 cases of type II pneumonia have been treated with concentrated type II serum, with a death rate of 40.5 per cent, while 253 alternate controls show a mortality of 45.8 per cent. The difference in the rates of the two groups is certainly not striking. Furthermore, it will be noticed that for two seasons the death rate in the treated series was slightly higher than that in the control.

It is interesting to compare the results of serum treatment in type II pneumonia at Bellevue Hospital with the results of well controlled series in other institutions. In table 8 the results of previously published studies are summarized. This comparison suggests more promising results for type II serum than were indicated in our own experience. All these investigators used Felton's serum and each used the alternate case method of control. In the total series the mortality rate in 232 cases of type II pneumonia treated with Felton's serum is 31.4 per cent, while in the 224 control cases it is 43.3 per cent.

Table 8.—*Comparison of Mortality Rate in Cases Treated with Felton's Concentrated Serum and Control Cases*

	Treated			Control

Total	232	73	31.4	224	97	43.3

* This series is included in the present study.

Although our own figures gave little, if any, evidence in support of type II concentrated serum, the more favorable results obtained by other investigators, as well as our own encouraging experience in early septic cases, led us in the fall of 1930 to continue the investigation. At that time, however, it was decided to limit serum treatment to patients admitted to the hospital within seventy-two hours of the onset of their infection, as it was thought that if the serum had any value it would be most evident in the early cases; moreover, it would be possible to give thorough serum treatment and more careful study to the smaller series.

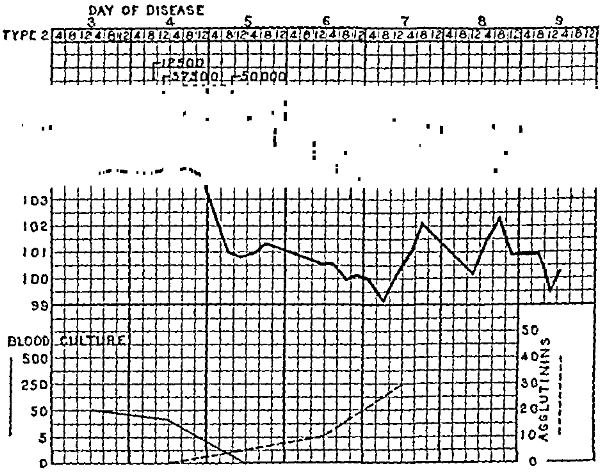

Chart 4.—Temperature, results of blood culture, and agglutinin titer of J. C., aged 44, with type II pneumococcus pneumonia, admitted to Bellevue Hospital on the third day of his illness. The blood culture on the day of admission showed 59 type II pneumococci per cubic centimeter of blood, and on the following day, the fourth day of the patient's illness, 28 organisms. On that day, 80 cc. (200,000 units) of Felton's concentrated serum was given intravenously. The temperature dropped from 104 to 101 F., the blood became sterile, the agglutinins in the blood began to rise, and the patient appeared less toxic. Serum treatment was continued on the fifth, sixth, seventh and eighth days of the illness to insure protection against a relapse.

The results of our 1930-1931 study, shown in table 9, are rather surprising. There were twenty control cases with thirteen deaths (65 per cent); and twenty-one cases treated with serum, with three deaths (14.3 per cent). Table 10 shows that the age and other complicating factors were slightly against the control cases, but not to such a degree as to be responsible for the marked difference in mortality rate. Furthermore, of all the patients who recovered, only two controls were septic, while six who were treated had pneumococci in the blood stream. These results are very encouraging but cannot be considered conclusive, because of the small number of cases in the series.

	Number of Cases	Deaths	Mortality, per Cent
Control	20	13	65.0
Treated	21	3	14.3

COMMENT

The present investigation has served to demonstrate that type II pneumonia, as it occurs in Bellevue Hospital, is one of the most serious infections encountered in this climate. The incidence of type II is considerably less than that of type I pneumonia, but the mortality rate is so much higher that the actual number of deaths resulting from type II pneumonia is greater than that from type I. The two diseases run a somewhat similar clinical course. However, empyema is a more frequent complication in type I pneumonia, while bacteremia is much more common in type II infection. Bacteremia is probably an important factor in the high death rate in type II pneumonia.

The time has come when we must think of the various pneumococcus "types" as etiologic agents of independent diseases. Such an attitude is necessary before the specific treatment of pneumonia can be put on a rational basis; and, furthermore, this etiologic diagnosis is of definite aid to the physician in making a prognosis. Let us visualize two patients with pneumonia on the fifth day of the disease, each with two lobes involved, and with a temperature of 104 F. What a difference there is in prognosis, if one patient has a type I infection with a sterile blood culture, and the other, a type II, with bacteremia! The former patient will probably recover; the latter will almost certainly die.

Table 10.—*Analyses of 1930-1931 Series*

	Control	Treated
Average age	42 years	37 years
Number over 60 years	4	3
Bacteremia on admission	9	7
Complicating systemic disease	5	6
Chronic alcoholism	8	7

The rapid methods of typing described in this article are comparatively simple and make it possible for the physician to know the pneumococcus type on the same day that the diagnosis of pneumonia is made. About 55 or 60 per cent of cases will fall into either the type I or the type II group. Every patient [illegible] pneumonia should have serum treatment. In [illegible] we have presented evidence that [illegible] refined serum has some therapeutic value in the treatment of type II pneumonia. Certainly, it appears more promising than any other form of specific treatment available. The carbohydrate-splitting enzyme that Avery and Dubos[21] have isolated offers hope for the eventual control of type III pneumonia, but thus far no enzyme has been discovered which affects type II organisms. Pneumococcus vaccine is being advocated by some for the treatment of all types of pneumonia, but evidence has not been furnished to prove that it affects the course or mortality rate of lobar pneumonia. Reports[22] have appeared recently which show a marked reduction in mortality rate following the use of vaccine, but the cases were not sufficiently studied, either clinically or bacteriologically, nor was the series well enough controlled to make the conclusions justifiable.

In attempting to evaluate the statistical evidence in support of type II serum, it must be remembered that the product which was used in the first years of our investigation was not nearly as potent as that which is now available. During the season of 1930-1931, the death rate in a group of twenty-one serum treated cases (admitted to the hospital early) was only 14.3 per cent, compared with 65 per cent for twenty early controls. This series of cases is too small to carry much significance. If, however, such a marked difference in mortality rate is [illegible] through the next [illegible] three seasons, it [illegible] strong evidence in favor of serum treatment.

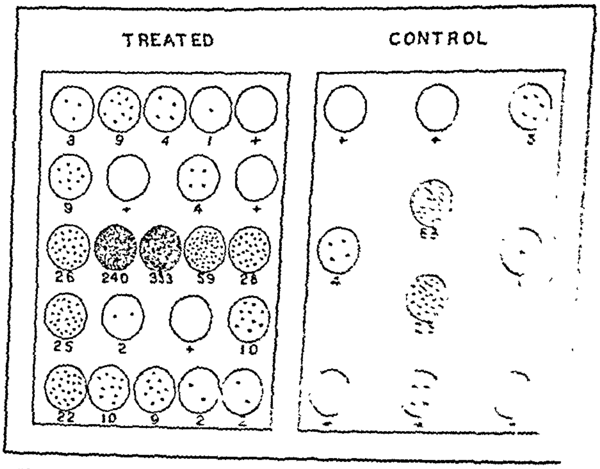

Chart 5.—Figures showing [illegible] recovered from type II [illegible] the treated, and the other, [illegible] culture plates, and the dots, [illegible] dots and with a plus (+) sign [illegible] was positive.

EFFECT OF TYPE II SERUM ON MORTALITY RATE

The effect of concentrated type II serum on the mortality rate of type II pneumonia is indicated by the year in table 7. Altogether 252 cases of type II pneumonia have been treated with concentrated type II serum, with a death rate of 40.5 per cent, while 253 alternate controls show a mortality of 45.8 per cent. The difference in the rates of the two groups is certainly not striking. Furthermore, it will be noticed that for two seasons the death rate in the treated series was slightly higher than that in the control.

It is interesting to compare the results of serum treatment in type II pneumonia at Bellevue Hospital with the results of well controlled series in other institutions. In table 8 the results of previously published studies are summarized. This comparison suggests more promising results for type II serum than were indicated in our own experience. All these investigators used Felton's serum and each used the alternate case method of control. In the total series the mortality rate in 232 cases of type II pneumonia treated with Felton's serum is 31.4 per cent, while in the 224 control cases it is 43.3 per cent.

COMMENT

The present investigation has served to demonstrate that type II pneumonia, as it occurs in Bellevue Hospital, is one of the most serious infections encountered in this climate. The incidence of type II is considerably less than that of type I pneumonia, but the mortality rate is so much higher that the actual number of deaths resulting from type II pneumonia is greater than that from type I. The two diseases run a somewhat similar clinical course. However, empyema is a more frequent complication in type I pneumonia, while bacteremia is much more common in type II infection. Bacteremia is probably an important factor in the high death rate in type II pneumonia.

The time has come when we must think of the various pneumococcus "types" as etiologic agents of independent diseases. Such an attitude is necessary before the specific treatment of pneumonia can be put on a rational basis; and, furthermore, this etiologic diagnosis is of definite aid to the physician in making a prognosis. Let us visualize two patients with pneumonia on the fifth day of the disease, each with two lobes involved, and with a temperature of 104 F. What a difference there is in prognosis, if one patient has a type I infection with a sterile blood culture, and the other, a type II, with bacteremia! The former patient will probably recover; the latter will almost certainly die.

TABLE 10.—*Analyses of 1930-1931 Series*

	Control	Treated
Average age	42 years	37 years
Number over 50 years	4	3
Bacterem[illegible]	9	7
Complica[illegible]	5	6
Chronic [illegible]	8	7

The rapid methods of typing described in this article are comparatively simple and make it possible for the physician to know the pneumococcus type on the same day that the diagnosis of pneumonia is made. About 55 or 60 per cent of cases will fall into either the type I or the type II group. Every patient with type I pneumonia should have serum treatment. In this article we have presented evidence that concentrated and refined serum has some therapeutic value in the treatment of type II pneumonia. Certainly, it appears more promising than any other form of specific treatment available. The carbohydrate-splitting enzyme that Avery and Dubos [21] have isolated offers hope for the eventual control of type III pneumonia, but thus far no enzyme has been discovered which affects type II organisms. Pneumococcus vaccine is being advocated by some for the treatment of all types of pneumonia, but evidence has not been furnished to prove that it affects the course or mortality rate of lobar pneumonia. Reports [22] have appeared recently which show a marked reduction in mortality rate following the use of vaccine, but the cases were not sufficiently studied, either clinically or bacteriologically, nor was the series well enough controlled to make the conclusions justifiable.

In attempting to evaluate the statistical evidence in support of type II serum, it must be remembered that the product which was used in the first years of our investigation was not nearly as potent as that which is now available. During the season of 1930-1931, the death rate in a group of twenty-one serum treated cases (admitted to the hospital early) was only 14.3 per cent, compared with 65 per cent for twenty early controls. This series of cases is too small to carry much significance. If, however, such a marked difference in mortality rate is maintained through the next two or three seasons, it will serve as strong evidence in favor of serum treatment.

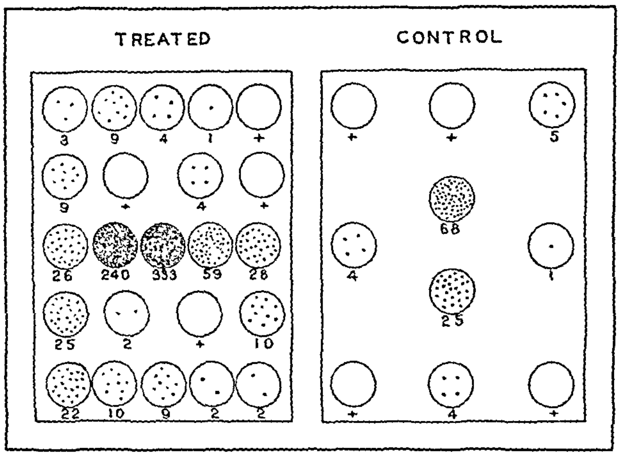

Chart 5.—Figures showing the results of blood culture in patients who recovered from type II pneumococcus bacteremia. One panel refers to the treated, and the other, to the control cases. The circles represent blood culture plates, and the dots, colonies of pneumococci. The circles without dots and with a plus (+) sign denote cultures in which the broth only was positive.

The effect of type II serum on the clinical course of type II pneumonia is certainly not as striking as that produced by refined serum in type I pneumonia. The sharp drop in temperature so often achieved in cases of type I infection treated early with serum is rarely obtained in type II cases. Serum-treated patients, however, appear less toxic and seem to run a somewhat milder course than the untreated.

Additional evidence in favor of type II serum lies in its effect on type II bacteremia. This is shown in a reduction of the mortality rate from 88 per cent in the septic cases without serum to 69 per cent in the septic cases with serum. An analysis of the recovered cases also shows a striking difference in the degree of bacteremia in the treated and untreated groups. This is clearly demonstrated in chart 5.

---

[21] Avery, O. T., and Dubos, René: The Protective Action of a Specific Enzyme Against Type III Pneumococcus Infection in Mice, J. Exper. Med. 54: 73-89 (July) 1931.

[22] Sutton, D. C.; Kendall, A. I., and Rosenblum, Albert: Immunizing Value of "Natural Bacterial Antigens," Study No. 1—Pneumococci, Am. J. M. Sc. 182: 454-459 (Oct.) 1931.

It is too early to pass final judgment on the efficacy of type II serum. More investigation with a highly potent product is required before a fair verdict can be given. It is significant, nevertheless, that those who have worked extensively with type II serum are confident that it has a place in the treatment of type II pneumonia.

SUMMARY AND CONCLUSIONS

1. This report is based on a clinical and bacteriologic study of 1,000 cases of pneumococcus type II pneumonia from the wards of Bellevue Hospital.
2. The bacteriologic and clinical methods employed are described. During the last three years of the study, particular attention has been given to rapid methods of typing the sputum.
3. Pneumococcus type II pneumonia is considered from the standpoint of a specific disease entity. Like type I pneumonia, it runs a characteristic febrile course, usually terminating by crisis.
4. Twenty-three per cent of 4,310 cases of pneumococcus lobar pneumonia in adults were type II infections. Only 9 out of 329 cases of pneumonia in children were of type II origin.
5. Curves of the age distribution of type I and type II pneumonia show a higher incidence of type I up to the age of 30, and a slightly higher incidence of type II beyond that age. Curves of the seasonal distribution of the two types are almost identical.
6. The incidence of complications in the entire series as well as in the cases that came to autopsy is tabulated for both type I and type II pneumonia. Empyema occurs twice as frequently in type I, while endocarditis is found twice as often in type II. Meningitis has the same incidence in both types. Bacteremia is almost twice as prevalent in type II as in type I infections.
7. Type II pneumonia has a mortality rate of 48.8 per cent, almost twice that of the type I variety. The death rate in septic type II cases is extremely high, 87.5 per cent in the present series.
8. The experimental evidence in support of type II serum and its concentrate is presented. The immune serum contains antibodies which react against the type II organism, and it also regularly protects mice and other laboratory animals from type II infection. Felton's concentrated serum is shown to be from six to twenty times as high as unrefined serum in its content of antibodies and protective substance.
9. A definite clinical effect following the early administration of concentrated type II serum is often demonstrable. The course of the disease is usually milder and the blood more frequently remains sterile.
10. In a series of 252 cases of type II pneumonia treated with Felton's concentrated serum the mortality rate was 40.5 per cent as compared with a death rate of 45.8 per cent in 253 alternate controls. During the last year of our investigation, only early cases of type II pneumonia were included in the therapeutic study. Twenty-one treated cases had the benefit of intensive serotherapy with a death rate of only 14.3 per cent, against a rate of 65 per cent for twenty controls. The latter series, however, is too small to be convincing.
11. The results presented in this paper indicate that type II concentrated serum has definite though not striking clinical value. At the present time it is the most promising therapeutic agent available for the treatment of this disease.

THE MANAGEMENT OF BREAST CANCER *

ALBERT SOILAND, M.D., D.M.R.E. (Cambridge)
LOS ANGELES

There are two distinct surgical methods for carcinoma of the breast, one radical, the other conservative. The conservative operator advocates a simple removal of the offending neoplasm without any attempt to extirpate glands from the surrounding areas, while the radical performer encourages the obliteration of all questionable tissue, including muscles and fascia, and the cleaning out of all gland-bearing spaces contiguous to the cancer field.

Among radiation therapeutists there is a similar dual point of view. Many radiologists are inclined to the use of light exposures in order to obtain palliation without endangering normal structures around the field; others take the opposite point of view and maintain the necessity of destroying all cancer cells in the involved area as well as every aberrant cell contiguous to the affected field. As with surgery so also with radiology; the two groups can find ample grounds on which to found their separate claims.

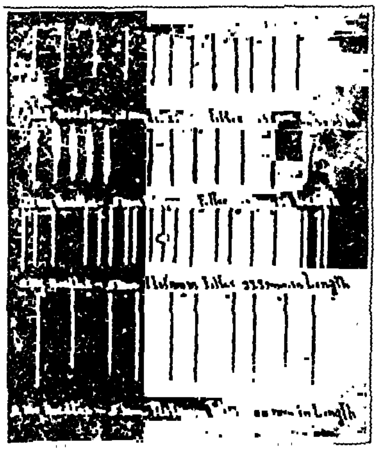

Fig. 1.—Types of radium filled platinum needles.

It was my privilege to present, at the London Congress in 1925, a paper on "The Treatment of Cancer of the Breast from the Viewpoint of a Radiologist," containing statistics of our own clinic, covering 550 patients observed over a sufficient length of time to warrant a report. In the intervening six years, many changes have occurred as related both to basic knowledge and to treatment methods. I have now modified and revised, to a considerable degree, my opinion of radium needles as then expressed.

My first success with radiation in a recurrent breast cancer was reported in 1901. Since then, upward of 3,000 patients with cancer of the breast have received treatment at our clinic. Obviously, it was impossible in earlier days to compile an accurate statistical study; therefore, only 550 patients were referred to in 1925.

Since then our recording and follow up methods have been greatly improved but, even yet, to obtain accurate and reliable cancer statistics is well nigh impossible. The ratio obtained in our 1925 report has not been materially increased in advanced cases; however, with the constantly increasing public knowledge regarding cancer, a greater number of patients are submitting to treatment at a sufficiently early stage to presage a definitely higher total of five-year clinical cures. Familiarity with the evolution of radiation standards will, no doubt, permit one to coincide with this conclusion.

---

* From the Soiland Clinic.

* Read before the Cancer Symposium at the Third International Congress of Radiology, Paris, July 30, 1931.

A short time ago, the surgical world was keenly interested when one of Britain's outstanding medical men announced having discontinued operative work on cancer of the breast in favor of radiation treatment; the latter, he stated, was giving him better results than surgery. Radiation therapy, as referred to here, is the interstitial implantation of platinum covered radium element needles, a method of treatment which offers all the benefit of close radiation without the disagreeable ulcerative reaction which accompanied earlier attempts to treat cancer below the surface with radium needles of low filter type.

This, then, is the method of radium therapy that I wish to present as the most promising and effective means at the present time. I desire to substantiate the preliminary report as given by that distinguished surgeon Lord Berkeley Moynihan, covering the original work done by Keynes, Handley, Cheatle, Cade and others.

For two years our clinic has employed the type of needles advocated by the authorities mentioned, and I am happy to state that the effects already observed are encouraging.

IMPLANTATION TECHNIC

Being privileged to take advantage of the pioneer work of the authorities quoted, as well as the observations of many other cancer workers throughout the world, and combining this with our own researches and conclusions, we have an approximately standard technic, particularly as related to preoperative breast cases.

With these patients the entire tumor mass is surrounded by implanted platinum covered needles, each needle containing from 1 to 2 mg. of radium and each of such a length as to be most suitable for the particular neoplasm submitted for dissolution. Great care is essential in order that the entire morbid area may come under an equalized crossfire of radium activity. The crux of the problem is to insure uniform radiation throughout the entire field involved. The work is accomplished with extreme mechanical and mathematical precision, the size and extent of each area to be treated being well determined, in order to insure the correct number of needles as well as the exact amount of radium to be applied.

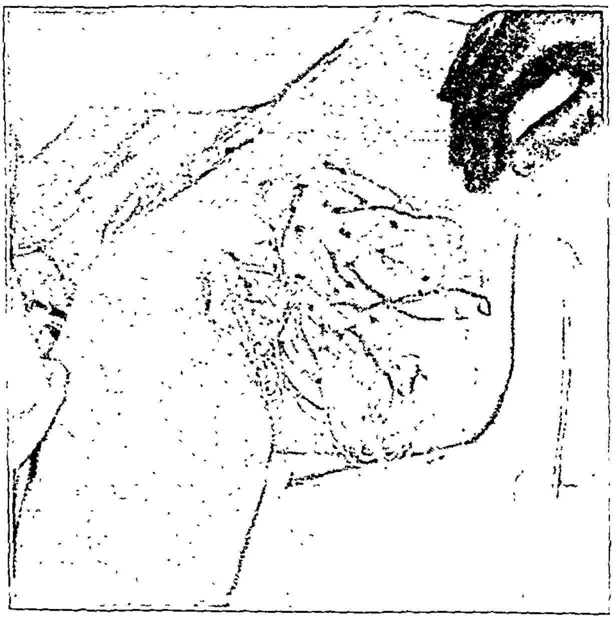

Fig. 2.—Needles containing radium implanted in breast, showing threads protruding.

With many cases one complete circle of implants is sufficient but others require a second ring of 3 cm. greater diameter and sometimes, with extensive involvements and large breasts, three encirclings are indicated.

In addition, all patients receiving interstitial radiation must have an implantation along the periphery of the breast, throughout the supraclavicular and infraclavicular spaces and the axillary area as well as the intercostal spaces and along the midaxillary line. These needles are left in situ for from seven to ten days, depending on the dosage prescribed. Usually from 75 to 80 mg. is required, although with some cases 100 mg. or even more may be necessary.

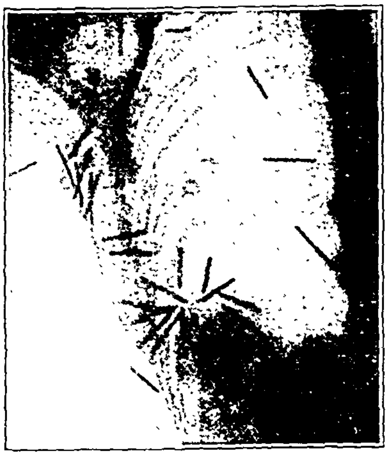

Fig. 3. — Arrangement and location of needles.

For this work, then, the use of fifty or more individual needles is entailed, all of which must be accurately placed and buried with consummate care in order that each and every individual cancer cell may be destroyed and that no outlying cell may remain beyond the reach of the radium barrage. Obviously, if one potential area of cancer-bearing tissue fails to be included, the effort will have been in vain.

The work is not easy. Experience shows that at least one hour is required to place and secure the needles properly in the average breast, and although this may be done under local anesthesia with certain patients, we favor a general anesthesia.

With nearly two years' work behind us, there is promise of much more positive results with implanted radium needles than we have heretofore attained through any other process of radiation therapy.

CLINICAL REACTIONS

Much care and patience must be exercised to see that embedded needles are at least 1 cm. distant from bone and periosteum. These tissues react negatively to prolonged irradiation, and, if already morbidly involved, should be destroyed by electrocoagulation or removed by the radio knife. Contrariwise, needles embedded in muscle, fascia, or lymphoid tissue may be permitted to remain throughout the full process of sterilization without any fear of lasting damage to contiguous normal structures.

As a usual thing, the average patient suffers but little inconvenience. Occasionally the axillary implantation has been found to cause some discomfort, particularly when much arm movement is indulged in.

It is essential also that patients be confined in bed during the required week or ten day period and it may be necessary with neurotic cases to offer a course of sedative remedies.

Usually there is but little radiation sickness, although it is well to alkalize the body and maintain a bland basic diet. Seldom is pain encountered, although an obstreperous patient may occasionally tax the clinician's patience and create difficulties which may require considerable finesse. As this is equally true in almost any therapeutic effort, it should not be considered as a deterrent for the treatment as advocated.

It is a simple matter to remove the needles, assuming that they have been properly secured to their protruding ligature with adhesive tape. Fortunately, the filtration rate of platinum prevents necrosis, and the little puncture wounds heal in a few days. The rapid melting away of malignant masses under this treatment is remarkable, and we have seen distended nodular breasts resume normal size and consistency with occasionally a return to lacteal function.

ECONOMICS

Let us now consider briefly the economic side of the problem.

Bearing in mind that the implantation of radium needles presents every aspect of a major surgical operation, the patient must be prepared with the care prescribed under the regulations of standard surgical technic and the radium embedded as required under the most rigid rules of aseptic surgery.

Appreciating the fact that the average neoplastic breast will have approximately $6,000 worth of radium tied up for a period of ten days, it is apparent that this type of treatment can be made available to only a limited number of sufferers. No individual radiologist could maintain sufficient radium needles to carry on a really extensive effort. It is extremely doubtful whether any hospital or institution is equipped, at the present time, to offer any broad service of this nature.

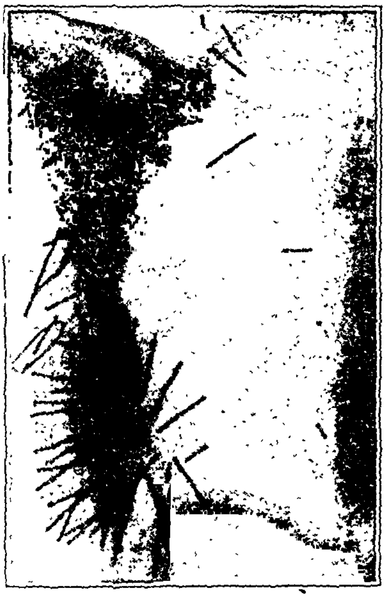

Fig. 4. — Arrangement and location of needles.

Therefore, until funds are available which will make possible an abundant investment in radium needles, this type of treatment presents itself as a serious economic problem. The present market quotation on radium shows no appreciable drop from the price which has been in effect for the past six or eight years; namely, $70 per milligram. To this must be added the cost of platinum and the highly skilled labor required for fabrication. These difficulties are worthy of serious thought when it is realized that no other method of applying radiant energy has secured results equal to those which have been attained through the direct action of embedded radium. Apparently, then, radium in the form mentioned must be obtained without regard to cost.

BUFFALO

Various kinds of organotherapy have been used in Addison's disease since the association of the suprarenals with that syndrome was pointed out by Addison in 1855. Kennicutt,[1] in 1897, reviewed the literature and reported that twenty-eight of forty-eight cases were improved by such therapy. In view of our present knowledge it is difficult to attribute the improvement in such a large proportion of cases to organotherapy. The remissions that may occur could account for the improvement in at least part of the cases. If improvement is very slow it may be independent of treatment. The best evidence of efficacy of organotherapy is the occurrence of relapse each time treatment is stopped.

Some success has been attributed to the use of whole suprarenal or of cortex by mouth together with epinephrine administered to the point of tolerance by rectum and subcutaneously.[2]

In October, 1927, Hartman, MacArthur and Hartman [3] described the first method for preparing an epinephrine-free, aqueous extract containing the vital hormone of the suprarenal cortex. The evidence that the hormone was present in this extract was the increased survival period of completely suprarenalectomized cats (twenty-one days as compared to six days for the controls). With such an extract it was possible to keep suprarenalectomized cats alive an average of twenty-eight days, as shown in a later report.[4]

Rogoff and Stewart [5] in October, 1927, reported increased survival of suprarenalectomized dogs treated with a saline extract of the suprarenal cortex. Their treated animals lived an average of 14.2 days, as compared to 9.6 days for the controls.[6] Since it was impossible to remove epinephrine by their method of extraction, the amount of hormone that could be injected was limited. The method of Hartman, MacArthur and Hartman permitted the injection of larger quantities of a more concentrated extract.

In March, 1930, Swingle and Pfiffner [7] reported results with a concentrated aqueous extract which kept suprarenalectomized cats alive indefinitely. In June,

1930, we[8] reported a rather simple method for producing a concentrated extract with low epinephrine content which would keep suprarenalectomized cats alive indefinitely and which would revive suprarenalectomized cats that were in the last stages of insufficiency. July 8, 1930, we treated our first case (case 1) of Addison's disease with this preparation.[9] Since then we have treated six other cases, which are included in this study.

USE OF THE ERGOMETER TO DETERMINE THE DEGREE OF ASTHENIA

Asthenia being the outstanding symptom in Addison's disease, an objective test for the determination of the fatigue point is highly desirable. Subjective estimates are unreliable. The ergometer, while it has its limitations, furnishes the most applicable objective test. It can be used at all times except when the patient is extremely weak. The fatigue point is far more important than the dynamic power of the muscle, since the latter does not respond readily to changes in the condition of the patient. The usual type of ergometer, which employs the middle finger, was used to determine the degree of asthenia at various times during observation and treatment. It seems most satisfactory to use a weight at first which, when lifted once every two seconds, causes fatigue in about three minutes. A sufficient number of tests is done to establish a base level, and then the patient is tested every week or so. It is not difficult to obtain base levels of work on the ergometer in asthenic patients while they are in the hospital.

In the severe cases, cortical insufficiency seems to be practically complete and cortin must be furnished in relatively large amounts indefinitely. In the less severe cases probably there is an appreciable amount of active cortex, but its functional capacity is considerably below bodily requirements. Intensive treatment for a limited period may bring about sufficient improvement so that the extract may be discontinued for a time. Certain symptoms suggest the presence of suprarenal insufficiency. In the absence of an unequivocal test, it is possible that the use of cortin, properly controlled, may be of diagnostic value.

In clinical cases, we have used extracts of the suprarenal cortex alone because we are not sure that the methods of separating cortin from the toxic substances of the medulla are entirely efficacious. We have used concentrations of cortin varying from the product of 15 to 50 Gm. of fresh cortex per cubic centimeter. In order to make our dosages comparable, we give them in terms of fresh cortex. The yield of cortin has been lower in the extracts made in larger quantities, because the suprarenals were at least a week old when received from the abattoir. There have been no toxic or disagreeable effects from the use of the extract except when a slight local reaction occurred in two instances. It can be given intravenously or subcutaneously. One patient was injected for nearly eight months, four times daily, without untoward results.

REPORT OF CASES

Case 1.—*History.*—A utility man, aged 24, was admitted to the Buffalo General Hospital, July 7, 1930. It appeared from his history that he considered himself well until April, 1930, when he had an attack of nausea and vomiting which lasted two days. He had another such attack in May. Since then he had become very weak and the vomiting had kept up. He had lost in weight from 170 to about 100 pounds (from 77 to 45 Kg.). On further questioning it was determined that he had experienced some fatigue at night after his day's work for about a year prior to the inception of his present illness, so that he did not care to leave his home at night. In 1928 he had scarlet fever and was ill about a month.

Physical Examination.—The patient seemed to be in extreme shock. His eyes were closed, he could not be aroused, and his legs seemed lifeless. His skin was diffusely tanned, especially over the face and arms, and there were many jet black freckles on his face, arms and chest. There was a small area of pigmentation on the mucous membrane of the gum over the upper left central incisor. His heart sounds were very distant. Systolic blood pressure was 50 and diastolic was 20. His legs twitched at times.

Laboratory Examination.—The urine was essentially normal. Chemical examination of the blood while the patient was fasting revealed sugar 82 mg. and urea 130 mg. per hundred cubic centimeters. The carbon dioxide capacity of the blood plasma was 27 mm. There were 21,600 leukocytes per cubic millimeter of blood, of which 76 per cent were polymorphonuclears.

Management and Course.—Artificial heat was supplied immediately. The patient was given repeatedly a 5 per cent solution of dextrose intravenously, and 1 cc. of 1:1,000 dilution of epinephrine chloride was administered subcutaneously every two hours. He did not appear to improve appreciably with this treatment. At the end of twenty-four hours he was given the extract of 3,000 Gm. of suprarenal cortex in fractional doses. The forcing of fluids was continued. His twitching gradually disappeared. His drowsiness continued, but he seemed less irritable and his mental response was better. After three more days of this treatment he began to eat and to read. July 16, another patient with Addison's disease was admitted, so that all the available cortin was divided between these two patients. July 19, the first patient began to lose interest in his surroundings, refused food, and vomited. He was then again given the extract of 3,000 Gm. of suprarenal cortex. July 20, he received the product of 4,800 Gm., and on the 21st, 2,400 Gm. He responded to treatment as before. Subsequently there were two other relapses due to reduction of the dose in order to determine his minimum requirement. With each relapse his blood urea value rose and the blood sugar dropped, but after improvement they returned to normal. Scaling of the skin, especially of the anterior abdominal wall, was found after each of the four relapses. His treatment was continued without interruption and by the end of seven months he was feeling much stronger. He could walk quite fast and could do eight times as much work on the ergometer as he could do originally. After he had been under treatment for 231 days, he developed a throat infection which was followed by bronchopneumonia. All the available cortin was given him. He died at the end of seven days.

Necropsy Report (by Dr. K. Terplan).[10]—The suprarenals showed extreme atrophy; each measured 4.5 by 1.4 cm.; the total weight of the two was 3.44 Gm.; they were ⅓ mm. in thickness. On the cut surface there were no normal markings. The parenchyma was grayish red. Histologic examination showed an absence of normal or regenerative cortical tissue except for one nodule, which was less than 1 mm. in diameter and which consisted of huge cortical cells containing lipoid but having degenerative changes in the cytoplasm. In the central portion of the suprarenals there were normally preserved medullary cells with chrome colored cytoplasm. In the outer portion there was in some places a complete absence of medullary substance. The cortex was largely made up of hyaline connective tissue.

Case 2.—*History.*—A housewife, aged 41, was admitted to the Buffalo General Hospital, July 16, 1930. In 1925, areas of vitiligo first appeared. A year later she had an attack of nausea and vomiting, pain in the upper right quadrant and diarrhea. This was diagnosed as acute cholecystitis. In 1927 weakness appeared, so that finally she was unable to do any of her housework. She was restless and did not sleep well.

[10] Terplan, K., and Sanes, S.: Pathological Report of a Case of Addison's Disease Treated with Cortin, Endocrinology **16**: 69 (Jan.-Feb.) 1932.

Her skin gradually darkened. Her family physician found her systolic blood pressure to be 72 and made a diagnosis of Addison's disease. She remained in bed for a whole year with no improvement. In 1929 she was ill with pleurisy for five weeks. During the six weeks prior to admission she had many attacks of nausea and vomiting and had to remain in bed all the time. Also, she had considerable pain in her legs and in her stomach.

Physical Examination.—The patient showed extreme prostration, was vomiting frequently, and complained of pain in the stomach. Her skin showed extreme vitiligo. There was one small area of pigmentation at the base of the tongue. The systolic blood pressure was 60 and the diastolic, 48.

Laboratory Examination.—Her blood count showed a moderate secondary anemia without leukocytosis. Blood dextrose was 116 mg. and urea 108 mg. per hundred cubic centimeters.

Management and Course.—On admission the extract of 100 Gm. of suprarenal cortex was given every four hours. She became gradually worse and died on the third day after admission. (From our experience with other cases we believe that this patient could have been saved, had a sufficient amount of cortin been available.)

Necropsy Report (by Dr. A. J. Foord).—There was an extreme atrophy of both suprarenal glands, so that they, together with the surrounding tissue, had to be fixed in solution of formaldehyde. Serial sections were made. The right gland was about 3 mm. in thickness and showed some hyperplasia of the cortical cells. The left gland was completely atrophied. There was healed tuberculosis in both pulmonary apices, recurrent cholecystitis, and marked lymphoid infiltration of and hyperplasia of the thyroid gland.

Case 3.—*History.*—A man, aged 38, a boilermaker, admitted to the Buffalo General Hospital, May 13, 1931, stated that he had been well up to June, 1930, when he had grip, which lasted two weeks, and that since that time he never regained his former strength. Six weeks later he had another similar attack. He worked until October 19, when he had to stop because of weakness which gradually increased and in December he was forced to go to bed. At that time he had nausea and vomiting. He remained in bed for three weeks, after which he began to get about. By April, 1931, he was able to walk from 600 to 800 yards. Pigmentation of his skin had been increasing since December, 1930. Many small jet black freckles had appeared on his arms, legs and face. He lost about 40 pounds (18 Kg.) from June, 1930, to the time he was admitted. He became irritable and had pains in his legs.

Physical Examination.—The patient was very poorly nourished and showed a diffused pigmentation of the skin of the entire body with darkening of the normally pigmented areas. There was pigmentation of the mucous membranes of the lips and of the inside of the cheeks. There were many jet black freckles. The rectal mucosa showed some pigmentation. The skin was generally very dry. His blood pressure was 80 systolic and 40 diastolic.

Laboratory Examination.—The urine showed albumin (from 1 plus to 2 plus) and the sediment usually contained many hyaline and granular casts. Red blood cells numbered 4,500,000; hemoglobin was 85 per cent; leukocytes were 14,000, 48 per cent of them being polymorphonuclears. A phenolsulphonphthalein kidney function test showed 16 per cent return of the dye in two hours; on subsequent examination, 29 per cent. Chemical examination of the blood with the patient fasting showed sugar, 67 mg., and urea, 33 mg. Gastric analysis showed the presence of free hydrochloric acid only after the administration of histamine. Basal metabolism was minus 17 per cent. The intradermal tuberculin test was positive. Roentgen examination of the suprarenal areas showed no evidence of calcification.

Management and Course.—On admission to the hospital the patient was very weak and had no appetite. While preliminary examinations were being made, he grew considerably worse, became very drowsy, vomited, and had incontinence of the bladder. During this time the urine showed an increasing amount of albumin and increasing numbers of casts. The blood urea increased to 90 mg. per hundred cubic centimeters. May 22, while the patient was in this state, the extract from 300 Gm. of suprarenal cortex daily was started in three divided doses. With this amount no improvement seemed evident, so that two days later the amount of cortin was doubled. He then became more alert, his appetite became better, and he took more interest in his surroundings. It was found necessary to increase the dosage of cortin up to the equivalent of 1,000 Gm. of suprarenal cortex a day. His appetite improved and he was able to be up and around the ward. However, he continued to lose weight. It was our belief that the dosage of cortin was inadequate, but more was not available. July 12, at 6 p. m., he complained of weakness which came on after a short walk in the ward. At 9 o'clock he was given orange juice and sugar. At 9:20 he stiffened out, all of his muscles went into spasm, and he became unconscious. His extremities were cold. His pulse was not obtainable and his heart sounds were inaudible. Respiration ceased for a time. He was given two intravenous injections of epinephrine chloride 1:1,000, 1 cc. each, and 60 cc. of a 50 per cent solution of dextrose intravenously. After this his pulse became palpable. At each prick of the needle his hands would go into clonic spasm and he would flex all four extremities. At 10 o'clock he was given the extract from 600 Gm. of suprarenal cortex subcutaneously and 1,500 cc. of a 5 per cent solution of dextrose in isotonic salt solution subcutaneously. At 11 o'clock he received 500 cc. of salt solution intravenously. At 11:30 the extract of 600 Gm. of suprarenal cortex was given subcutaneously. His general condition was now somewhat improved, although Cheyne-Stokes type of respiration was present. At 1:15 a. m. he received another subcutaneous injection of cortin consisting of 600 Gm. of suprarenal cortex, and 500 cc. of a 10 per cent solution of dextrose intravenously. His blood pressure was now 90 systolic and 50 diastolic. At 2:25 he received an intravenous injection of cortin, consisting of 600 Gm. of suprarenal cortex. At 3:15 the patient was resting quietly but became irritable and flexed his extremities when the sphygmomanometer cuff was blown up. At 4:35 there was considerable twitching of the muscles of the pectoral group and of the arm. At 6 o'clock he received another intravenous injection of cortin. Muscular twitchings and general irritability had now ceased. During the day he was given large quantities of a 5 per cent solution of dextrose subcutaneously. There was some twitching of the face and lips at times. He had periods when he appeared somewhat rational. July 14, he was becoming calm and he was drowsy a great deal of the time. The subcutaneous injections of cortin were continued. On the 15th, his appetite returned and he was irrational for only a short time. His blood urea dropped from 92 (July 11) to 47 mg. (July 17). From that time on he has shown gradual but definite improvement. His weight, which was 95 pounds (43 Kg.) on admission and 85 pounds (38.6 Kg.), July 6, reached 104 pounds (47 Kg.), October 12. He returned to his home the middle of October, where cortin was administered by a member of his family. When he came back to the hospital in ten days, as requested, it was found that he had gained 8 more pounds and felt very well. He was able to walk more than a mile at a time without fatigue, and his capacity on the ergometer was twice what it was at his first admission. His blood urea was 81 mg. per hundred cubic centimeters. There was the faintest trace of albumin in the urine and occasional granular and hyaline casts. The specific gravity of the urine was 1.018. His dose of cortin was the product of 1,200 Gm. of cortical tissue daily.

Case 4.—*History.*—An unmarried woman, aged 38, first seen by one of us, Sept. 26, 1931, had observed pigmentation on her gums four years before. Later, black freckles appeared on her arms, legs and face. There were also, as time went on, distinctly darker areas appearing on her body. Eight months before, she was admitted to the hospital with a diagnosis of "acute cholecystitis and hyposuprarenalinism." Since that time she had had periods when it has been necessary for her to remain in bed for a few days because of weakness. She usually had vomiting with these attacks. In the intervals she felt better and was able to be around but she never returned to her former health. She had had distress in the stomach for several years. She felt chilly in a room that was warm enough for others. Fainting spells had occurred frequently, especially in the past few months. She experienced some breathlessness on exertion.

Her weight was 116 pounds (52.6 Kg.), which represented a loss of 60 pounds (27 Kg.) in a year.

Physical Examination.—The patient was quite restless. There was some evidence of dehydration. There were areas of pigmentation on the arms, elbows and face. There were black freckles on the arms, legs and face. There was diffuse tenderness of the whole abdomen but no muscular spasm. The blood pressure ranged between 94 and 104, systolic, and 68 and 74, diastolic. The pulse rate was between 90 and 100.

Laboratory Examination.—As this patient was out of the city, it was impossible to get complete laboratory data. The blood sugar was 70 and the nonprotein nitrogen was 51 mg. per hundred cubic centimeters.

Management and Course.—The patient was given the extract of 200 Gm. of suprarenal cortex three times a day, beginning September 26, at 2 a. m. Soon after the first injection she went to sleep and slept continuously for six hours. She had had no sleep for the three preceding nights. She took some breakfast, and there was no vomiting for the first time in two weeks. She drank water and ate during the day without vomiting. Since that time her improvement has continued, and she has eaten well. Her weight, October 12, was 128 pounds (58 Kg.) and, October 20, her blood pressure was 110 systolic and 78 diastolic. She has been about the house, and her pigmentation has decreased so that her relatives say it is nearly normal.

Case 5.—*History.*—A housewife, aged 41, admitted to the Buffalo General Hospital, May 28, 1931, had been well up to September, 1930, except for occasional bilious and fainting attacks, which would appear if she injured herself. At that time she noticed weakness after exercise. This gradually became worse until March, 1931, when she became very weak. She had some twitchings of the legs so that she would have to get up and walk at night. She experienced tightness in the chest after walking a short distance. She had lost 30 pounds (13.6 Kg.) in the past two years. About March 1, it was noticed that her skin was becoming darker and about that time palpitation after exercise developed. She had considerable nausea and vomiting during April, 1931. She was restless and irritable and did not sleep well.

Physical Examination.—The patient weighed 96 pounds (43.5 Kg.). The skin was diffusely darkened. The nipples were very much pigmented. There were small areas of pigmentation in the mucous membrane of the mouth just inside the lip margins. The blood pressure was 90 systolic and 70 diastolic. The abdomen was normal.

Laboratory Examination.—The urine was normal. Red blood cells numbered 3,990,000; hemoglobin was 70 per cent; leukocytes numbered 5,600, 62 per cent of which were polymorphonuclears. Chemical examination of the blood, fasting, revealed sugar, 90 mg., and urea, 40 mg. per hundred cubic centimeters. Basal metabolism was minus 9 per cent.

Management and Course.—The patient received the extract from 600 Gm. of suprarenal cortex daily in three divided doses. In four days she felt stronger and could then do twice as much work on the ergometer as she could on admission. She slept much better and was not so "nervous" and irritable. The twitching in the legs and the tightness in her chest after exercise disappeared. After six days of treatment she could do four times as much work on the ergometer and was sleeping and eating normally. She left the hospital, June 16, continuing the extract of 400 Gm. of cortical substance daily.

July 9, she walked up two flights of stairs without difficulty for the first time since treatment had been instituted. The dose of cortical extract was then reduced to the product of 200 Gm. daily. At this time she returned home, 150 miles by train. There she began to feel much weaker, slept poorly, was irritable, and at times was despondent. The dosage of cortin was then doubled, and within forty-eight hours her condition was noticeably improved in that she slept better and acquired an improved sense of well being and was not so irritable. Her weight had now increased 7 pounds (3.2 Kg.). August 6, she did six times as much work with the ergometer as she did when first seen. Pigmentation was definitely diminished.

November 3, the patient wrote that she was able to carry out the ordinary activities of her daily life without difficulty.

Case 6.—*History.*—A woman, aged 55, a clerk, admitted to the Buffalo General Hospital, Nov. 19, 1930, had been unable to do her routine work without noticeable fatigue since 1924. She was drowsy and dizzy, and had had fainting spells for many years. In 1926 she observed the appearance of brownish areas on her face, neck and back. Her appetite had been fair and there had been no nausea or distress in her stomach. She had lost some weight.

Physical Examination.—The patient was somewhat undernourished and her skin was considerably darkened, especially in areas about the face, neck and back. Her voice was husky and she was easily fatigued. The blood pressure was 90 systolic and 60 diastolic. The examination of the abdomen was negative.

Laboratory Examination.—The urine was normal. Red blood cells numbered 3,110,000; hemoglobin was 60 per cent; white blood cells numbered 7,500, 54 per cent of which were polymorphonuclears. Chemical examination of the blood revealed sugar, 88 mg.; urea, 22 mg. The basal metabolism was about minus 28 per cent on three determinations. The oral temperature had a subnormal range. There was no free hydrochloric acid in the stomach contents until histamine was given.

Management and Course.—The diagnosis seemed uncertain. The patient had received thyroid medication in the past with questionable benefit. She had not been taking thyroid recently. She remained at rest in the hospital for nine days, during which time her ability to work without fatigue was established with the ergometer. Cortical extract, 300 Gm., subcutaneously, was then given twice daily during eight of eleven days. The length of time she could work on the ergometer without fatigue lengthened gradually, so that thirteen days after the discontinuance of cortin she could do twenty-eight times as much work as before treatment was begun. Her basal metabolism during this time remained unchanged. She had no cortin for fifty days, but her ability to work remained between two and three times what it was before treatment. Thyroid medication, 0.13 Gm. daily, was then administered until the basal metabolism reached normal. After she had been taking thyroid one month her ability to work without fatigue increased to eight times what it was originally. Cortical extract, 600 Gm., was now given daily for nine days in addition to the thyroid medication. Four days after cortin was stopped she could do thirty-eight times as much work with the ergometer as originally.

She has received no medication since Aug. 1, 1931, but has continued to feel well. She has gained 2 pounds (0.9 Kg.) and is able to do her work. Her pigmentation seems to be less. October 12, her basal metabolism was minus 23 per cent. Her chief complaint at that time was that she was exceedingly sensitive to cold.

Case 7.—*History.*—A woman, aged 41, a housewife, admitted to the Buffalo General Hospital, April 2, 1931, had noticed fatigue after a day of ordinary housework since the summer of 1930. This gradually increased so that before admission she found difficulty in carrying on her work. She had aches in the back and legs, especially when she walked up or down stairs. Very unpleasant nightmares had been present for the past two years. She was very easily irritated and disturbed. Her skin had become darker on her neck since 1921, and the pigmentation had spread to the chest and back. Her appetite had remained good and she had lost but little weight. She had no stomach trouble.

Physical Examination.—The patient was well nourished and did not appear especially ill. There was slight brownish pigmentation of the skin of the neck, chest and back, but none on the mucous membranes. Her blood pressure was 104 systolic and 80 diastolic. There was definite diminution in strength on squeezing the examiner's hands and extending the legs from a state of flexion against resistance.

Laboratory Examination.—The urine was normal. Red blood cells numbered 4,380,000; hemoglobin was 75 per cent; white blood cells numbered 9,900, of which 68 per cent were polymorphonuclears. Chemical examination of the blood showed dextrose, 84 mg.; urea, 24 mg. Basal metabolism was minus 12.7 per cent.

Management and Course.—Before treatment with cortin was begun the patient rested at home for fifteen days. There did not seem to be any improvement. The extract of 150 Gm. of suprarenal cortex was given twice daily. In three days she stated that she experienced less fatigue. At that time she could do 50 per cent more work with the ergometer than on admission. In six days she could climb stairs without fatigue, which she could not do previously. The pain in her back and legs and the nightmares disappeared. April 28, the work that she could do on the ergometer had increased 150 per cent. Cortical extract was then increased to double the original dose, now 600 Gm. daily. May 7, the daily dose was reduced to 300 Gm. May 29, it was discontinued altogether. She, however, continued to improve in every way. Two weeks after cortin was discontinued she was able to do ten times the work originally done with the ergometer. She felt better than she had in the past two years and was able to work about the farm and to drive her own car. When seen again, August 5, her symptoms were beginning to return—backache, irritability, weakness and aching in the legs. She had been through a severe emotional strain because of the death of a member of her family. August 20, she reported that she had been relieved of household duties and had remained in bed much of the time. We were not certain that there was not a psychic element in her case, so she was given two injections daily of isotonic salt solution. In eleven days she reported that her fatigue was somewhat better. September 1, she was given the extract of 75 Gm. of cortical substance twice daily. In three days, greater improvement was reported. She slept better and was not so irritable. The aching in the legs had subsided and fatigue on going up and down stairs had lessened decidedly. At that time she could do seven and one-half times as much work with the ergometer as when first seen.

COMMENT

Relapses; Recovery with Cortin.—The first symptoms that appear in a relapse are most likely to be anorexia, vomiting, epigastric discomfort and lethargy or irritability. There may be pains in the legs, back or abdomen. Insomnia and mental depression may follow. If the relapse is serious the blood pressure falls, the blood urea rises and the blood sugar may drop. Although the changes may seem to be coming on gradually, collapse and coma may occur in a few hours. Once there is evidence of an increasing cortical insufficiency, treatment should be instituted speedily. In order to be on the safe side, large amounts of cortin should be injected, because it often requires much more of this hormone to pull the patient through a relapse than it does to carry him at a level of comparative health, once that is attained. Two patients came out of coma and one recovered from collapse three times following the use of cortin.

As a patient becomes worse, his condition may change so rapidly that some of the stages may not appear or may be overlooked. During the process of recovery, these stages occur in the reverse order and develop more gradually, so that they may be more easily studied. Coma may alternate with periods of restlessness and irritability. During this stage there may be muscular twitching and irregular breathing. As consciousness returns, restlessness, twitching and irritability may increase and there may be vomiting. Pains in the abdomen, legs or back may appear; the patient is disoriented, may be mentally irritable and fails to cooperate. He passes through a period of depression and listlessness. His judgment is poor and insomnia may develop. As improvement progresses, the twitching disappears and restlessness is replaced by calm; the patient is less irritable, becomes free from pain and shows proper orientation. At first he may sleep a great deal. Within three days after treatment is instituted, he usually reaches the stage of recovery, which is characterized by mental alertness, a decrease of asthenia and a return of appetite. The patient soon recovers his sense of well being; good judgment returns and he is cooperative. His sleep becomes restful, so that he is awake about the same proportion of time as a normal individual. Cortical extract seems to be very beneficial in bringing restful sleep, especially in the milder cases. We group tentatively these changes into four phases—coma, irritability, calm and recovery. The time required to pass through these stages to recovery varies. It probably depends on the dosage of cortin and on the condition of the patient when the relapse occurs. It has been possible to bring about rapid recovery in suprarenalectomized cats that had been allowed to pass into the last stage of suprarenal insufficiency before death; one was prostrate, dyspneic and had marked muscular twitching in different parts of the body. The injection of cortin, intraperitoneally, caused the twitching and dyspnea to disappear within an hour. In seventy minutes she sat up and in an hour and forty minutes she was eating. Other cats that have passed more slowly into this stage of extreme suprarenal insufficiency have required a longer period, sometimes even days, for recovery. Also, some have required larger quantities of cortin to bring them out of coma. Occasionally, however, animals that have been allowed to pass into the last stages of prostration did not recover when treated with large amounts of potent extract. This leads us to believe that there are stages beyond which one dares not allow the patient to go without instituting treatment. The signs and symptoms in relapse and recovery are similar in animals and in man.

Gastro-Intestinal Symptoms.—Gastro-intestinal symptoms which were confined to capricious appetite or epigastric discomfort in the mild cases developed into marked anorexia with nausea and persistent vomiting in severe cases, particularly at the time of the crisis. Following the use of cortin, response to treatment was evidenced by a return of or an increase in appetite; and there was a prompt cessation of the nausea and vomiting, usually within twenty-four hours.

Asthenia and Blood Pressure.—In severe cases, although there may be prompt recovery to a certain level of fatigue resistance, it may be weeks before further increased fatigue resistance is shown either subjectively or with the ergometer.

In mild cases treatment has been followed by improvement in the ergometric test within a few days. Sometimes this is shown by the test before the patient realizes that he is definitely stronger. This is soon reflected, however, in his increased ability to carry on the affairs of daily life.

The improvement in strength is not accompanied by an appreciable change in the blood pressure. In the majority of these cases the systolic blood pressure does not elevate above from 100 to 110, and the only striking elevations in blood pressure were those shown following relapses, when a systolic pressure, which had fallen to 60 mm. or less, would return to the neighborhood of 100 mm. after several days. Case 3 is an exception, the systolic pressure not having risen much above 85 mm. The ergometric response was appreciable in all the cases and very marked in case 6.

Skin.—Pigmentation: There has been a decrease in the pigmentation in four of our cases after the use of cortin. In three this has been quite decided. On the other hand patient 1, who was kept alive with cortin for nearly eight months, was becoming darker during the last few months in spite of striking improvement in other ways. These changes have been determined by the use of a color dictionary.

Desquamation: After recovery from each relapse in our severe cases there has been desquamation over the body but especially on the anterior abdominal wall and the forehead. No effect on the hair was observed. It is interesting to note that suprarenalectomized cats may show skin changes. A freshly shaven area in a white cat shows a dirty gray and poorly nourished skin; the hair falls out easily or can be pulled out in masses. A normal cat, however, shows instead a pink healthy skin with tight hair. Sufficient cortin administered to suprarenalectomized animals brings back the normal qualities of the skin, and the hair again becomes fixed.

Temperature Regulation and Metabolism.—All of our cases have shown a subnormal temperature before and after treatment except for an occasional rise due to intravenous medication or to infection. During relapses, patients complain of cold extremities; this is probably due to faulty circulation as well as to lowered heat production. Individuals with suprarenal insufficiency are more susceptible to cold and therefore must be carefully protected even from moderate exposure. This inability to resist cold is due to lowered heat production. The basal metabolism of our patients has been below normal, though not strikingly so. Following suprarenalectomy, the metabolism of rats also falls (minus 10 to 20 per cent). On exposure to cold such animals may increase their heat production at first but the response soon falls far below that of normal animals.[11] As a result, the temperature falls and the animal dies if the exposure is prolonged. If they are injected with an adequate amount of cortin, the resistance to cold of suprarenalectomized animals is increased by enabling them to produce more heat; thus they stand exposure almost as well as normal animals. The metabolism of patients with suprarenal insufficiency has not been brought to normal by treatment possibly because the dosage was insufficient. Judging from the amount necessary to produce such a response in animals, it would be necessary to use from ten to thirty times as much cortin as we have used in the most serious cases of Addison's disease. However, there is some evidence that small animals require proportionately larger amounts of cortin.

Patients with marked suprarenal insufficiency have a lowered resistance to heat. Patient 1, when in excellent condition, was allowed to sit in the winter sunshine while he was tested with the ergometer. At the end of the test, which he had accomplished many times before without general fatigue, he felt so tired that he asked to lie down. Another case of Addison's disease not included in this report was found to show a low resistance to heat.

Weight.—All of our patients who have responded to treatment have shown a gain in weight. In the severe cases, this gain has been very much delayed. A gain in weight is undoubtedly a good prognostic sign and in the severe cases a failure to gain is an indication for increasing the dosage of cortin.

Laboratory Observations.—Cases of any severity commonly show an increase in blood urea, which usually varies in direct proportion to the patient's state. In a crisis the urea may rise, and in one of our cases it was well over 100 mg. per hundred cubic centimeters of blood. When sufficient amounts of cortin were given, the urea was reduced to normal in all cases save one. In some patients this response has been prompt, but in others it has been delayed and has not paralleled clinical improvement. When insufficient cortin was given, the normal blood urea was not reached. The severer cases showed lowered blood dextrose, which usually rose after the use of cortin. The severe cases showed a mild degree of secondary anemia, which improved under treatment. Abnormal urinary manifestations were recorded only during a relapse when there was a tendency for fairly large quantities of albumin and many casts to be present. No glycosuria was noted, despite the administration of considerable quantities of dextrose by various avenues during certain stages of treatment.

Dosage of Cortin.—The requirements of different patients for cortin vary over a wide range, depending no doubt on the degree of suprarenal insufficiency and also on individual variation. It has been found in animals with complete suprarenalectomy that the amount of cortin required to keep them in good condition varies considerably. This variation exists even under optimum conditions, but with infections, trauma and exercise much more cortin is needed.[12] When the requirements are not great, the doses not only are small but need not be given frequently. As the patient's demands for cortin increase, the dosages must be stepped up both in quantity and in frequency, as is necessary, for example, in infections or in trauma. This obtains in animals and seems to be true in man. The daily total requirements both in man and in animals seem to be less if the dosage is frequent. For instance, in case 1 the product of 1,200 Gm. of cortex distributed in four doses was more effective than that from 1,800 Gm. given in three doses. If our patients become worse we always increase the frequency of the dosage.

Rowntree, Greene, Swingle and Pfiffner[13] have used an extract of the suprarenal cortex. Judging from their reports, their results have been similar to our own. Ball and Lansbury[14] have reported another case treated with cortical extract. Simpson[15] has treated five cases. Patients not under our control have been treated by an extract prepared in our laboratory. Fuller Albright and P. C. Baird administered this extract in three cases of Addison's disease in the Massachusetts General Hospital and Allan T. Kenyon in one case of Addison's disease in the Billings Memorial Hospital at Chicago. Their results confirm our own.

CONCLUSIONS

Of seven cases treated with cortin, three represented severe stages of Addison's disease and four others presented less severe aspects of the syndrome.

Conclusive evidence has been furnished that an extract of the suprarenal cortex prepared by the ether-alcohol method is effective in alleviating the symptoms of Addison's disease.

THE MIGRATION, FOR TREATMENT, OF PATIENTS WITH GONORRHEA OR SYPHILIS

COMPARISON WITH THAT OF PATIENTS WITH TUBERCULOSIS IN MASSACHUSETTS IN 1930 *

N. A. NELSON, M.D.
AND
HENRY M. DeWOLFE, M.D.
BOSTON

Many opinions have been expressed, founded largely on impression, as to the extent to which patients leave their home towns for treatment of gonorrhea or syphilis, and as to why and to what extent they choose between physicians and clinics. The desire for secrecy, the scarcity of specialists in the smaller communities, the high cost of adequate treatment, the availability of clinics and other reasons are advanced in behalf of the various opinions. Actual data to support these impressions are lacking.

The Massachusetts Department of Public Health recently modified its system of reporting gonorrhea and syphilis. As one result of this change it has been possible to study some of these obscure matters and to arrive at some conclusions of qualitative, if not quantitative, value.

Unfortunately, since the new system went into effect on Jan. 1, 1930, only some 6,200 cases of gonorrhea and 3,500 cases of syphilis, reported by clinics and physicians in 1930, have been available for study. However, the analysis of even this relatively small number of cases has greatly strengthened some of our former impressions and has severely shaken others. At least there is now some groundwork for further investigation.

Preliminary study[1] indicated that the combined migration for the two diseases was more than a quarter of the total cases reported and varied inversely as the size of the community, from 70 per cent in the smaller towns to less than 5 per cent in the largest cities. This variation did not appear in the twenty-one cities and towns in the Boston Metropolitan Area, in which nearly three fourths of the patients migrated (except from Boston), regardless of the size of the community.

Table 1.—*Distribution of Population and Reported Case Rates in Massachusetts, 1930*

Size of Community	No. of Communities	Population*	Gonorrhea Cases	Gonorrhea Rate†	Syphilis Cases	Syphilis Rate†	Per Cent of Total: Population	Per Cent of Total: Gonorrhea	Per Cent of Total: Syphilis
Under 20,000	314	1,196,101	944	78.9	509	42.6	28.1	13.5	12.1
20,000-50,000	25	823,194	1,001	121.7	470	57.2	19.4	14.4	11.2

* Population as of July 1, 1930.
† Per 100,000 population. Includes patients in institutions.
‡ Lowell included: population, 99,733.

Further study has disclosed significant differences between the migration of patients with gonorrhea and of those with syphilis. Migration of the two sexes has been compared and also that in those communities which have or are near clinics with those which are far from clinics. The attraction which Boston has as a medical center is also studied, as it appears to have a large influence on the direction of the migration.

Those cases which were reported from penal institutions, mental disease hospitals, and the like, are not included in this study. Inmates of these institutions have no freedom of motion. A study of migration must take into account the opportunity which the patient may have for choosing between the various treatment resources.

GENERAL DATA

Table 1 presents certain pertinent information concerning the distribution of the population of Massachusetts and the reported rates for gonorrhea and syphilis. The increase in rates with the increase in the size of the community and the high rates and the percentage of the total cases in Boston should be noted.

There are approximately 5,800 physicians practicing in the state. Tables 2, 3 and 4 will orient the reader somewhat as to the distribution of these physicians, the extent to which they report cases and the availability of "specialists." The smaller the community, the greater is the percentage of physicians reporting gonorrhea, while the opposite is true of syphilis.

Table 2.—*Distribution of 5,829 Physicians: Reporting of Cases by Physicians*

Size of Community	Per Cent of Population	Per Cent of Physicians	Per Cent of Those in State Who Reported: Gonorrhea	Per Cent of Those in State Who Reported: Syphilis	Per Cent of Local Physicians Reporting: Gonorrhea	Per Cent of Local Physicians Reporting: Syphilis
Under 20,000*........	28.1	18.5	22.8	12.2	18.8	5.4
20,000-50,000..........	19.4	14.9	18.2	14.5	18.6	8.0
50,000-100,000.........	10.9	8.1	7.2	7.1	13.4	6.9
100,000-over..........	23.3	21.9	20.2	24.9	14.1	9.3
Boston..............	18.3	36.6	31.6	41.3	13.1	9.2
State............	100.0	100.0	100.0	100.0	15.2	8.1

* *Ninety-eight towns under 20,000 population do not, according to our records, have a resident physician.*

Data now being collected for future study seem to indicate that between 50 and 60 per cent of the physicians in the state treat gonorrhea and that between 40 and 50 per cent treat syphilis. By far the majority of these treat only as occasion demands, less than 2 per cent classifying themselves as "specialists." Apparently, then, less than a third of those treating gonorrhea and less than a fifth of those treating syphilis report their cases. It is known that not all their cases are reported even by those who do report. (Among 361 physicians who received arsenicals from the department in 1930, only 48 per cent reported cases of syphilis.)

There are twenty-nine public clinics in Massachusetts at which patients may be treated for either gonorrhea or syphilis. Eleven of these are located in Boston, four others in the Boston Metropolitan Health District;[2] and fourteen in twelve of the larger cities of the state. Not one of these cities is of less than 40,000 population (Brockton, Fall River, Fitchburg, Haverhill, Holyoke, Lawrence, Lowell, Lynn, New Bedford, Pittsfield, Springfield and Worcester). Large areas of the state are out of reach of clinics, but the total population of these areas is relatively small. These twenty-nine clinics are available to 2,152,000 people in the cities in which they are located comprising 50 per cent of the population of the state. An additional 1,046,000 people are residents of eighty-one other communities immediately adjacent to these clinic cities. Therefore, at least 75 per cent of the population of the state has clinic service almost directly at hand. The remainder, largely residents of small towns, have low reported rates of either disease, so that it is probable that more than 75 per cent of the infected population has clinic service available.

Table 3.—*Physicians in Boston and in the Health District of Metropolitan Boston* [2]

	Per Cent of Population of State	Per Cent of Physicians of State	Per Cent of Those Physicians Reporting: Gonorrhea	Per Cent of Those Physicians Reporting: Syphilis	Per Cent of Those Cases Reported by Physicians: Gonorrhea	Per Cent of Those Cases Reported by Physicians: Syphilis
Boston	18	37	32	41	30	30
Boston Health Area	39	52	50	55	51	51
Remainder of state	61	48	50	45	49	49

Examination of clinic records reveals that, with the exception of two or three of the smaller clinics, practically all clinic cases are reported. Consequently, in drawing conclusions it must be remembered that less than a third of the cases seen by physicians are reported, while most of the clinic cases are reported.

THE MIGRATION OF PATIENTS WITH GONORRHEA

Table 5 gives the percentage of migration from communities of different sizes, the percentage of cases reported by local physicians and clinics, and the total percentage of cases reported by physicians and by clinics, whether local or foreign.

It is surprising to discover that nearly 45 per cent of the reported cases are reported by local physicians, no matter how small or how large the community. This is interesting in view of the often repeated assertion that patients in small towns prefer the security of distant physicians' offices, away from the eyes of inquisitive neighbors, and that clinics in the larger cities are putting the physician "next door" out of business.

Table 4.—*Distribution of Reported Cases Among the Physicians Reporting*

(3,749 Cases of Gonorrhea Reported by 886 Physicians)

49.9% reported by 10% of physicians reporting (10 to 89 cases each)
70.3% reported by 25% of physicians reporting (5 to 89 cases each)
86.5% reported by 50% of physicians reporting (3 to 89 cases each)

(1,131 Cases of Syphilis Reported by 474 Physicians

37.1% reported by 10% of physicians reporting (5 to 38 cases each)
58.0% reported by 25% of physicians reporting (3 to 38 cases each)
78.9% reported by 50% of physicians reporting (2 to 38 cases each)

Even among the migrating patients, more went to physicians than to clinics from communities of all sizes.

It does appear, at first glance, that more patients are treated by clinics than by physicians as the size of the community (and, therefore, the availability of a clinic) increases. We are of the opinion that this choice of clinic in preference to physician is more apparent than real and offer first an hypothesis and then evidence which seems to support it. The smaller communities have no clinics and are often distant from clinics. There must be a point at which the cost of transportation to a clinic becomes equal to or passes the cost of treatment with a physician. Nor can patients who cannot afford a physician afford to travel to the nearest clinic. Consequently they go without medical care. As only those patients who can afford a physician get medical care, only cases seen by a physician are reported. If this is true, the reported rates of gonorrhea from those communities distant from clinics should be appreciably lower than the reported rates for communities of the same size which have, or are located nearer to, clinics. This we find to be, very strikingly, the case (table 6).

Further, clinics report most of their cases, but physicians do not. Therefore the distribution of cases between clinic and physician in clinic cities is, on the face of reports, disproportionate in the opposite direction. In the small communities, the proportion of clinic cases is low because the clinic type of case gets no treatment because travel costs as much as the physician he cannot afford; on the other hand, the proportion of clinic cases is high in clinic cities because clinics do, and physicians do not, report most of their cases.

Certainly, the more directly available a good clinic, the greater will be the temptation of those who are only in fair economic condition to go to the clinic. But this temptation is not as effective as the complaints of many physicians would make it appear. It seems, rather, that when clinics are not available the greater part of the "clinic" population goes without treatment.

Table 5.—*Migration of Patients with Gonorrhea (Per Cent of Total)*

Size of Community	Total Cases	Migrated to: M.D.	Migrated to: Clinic	Migrated to: Total	Treated Locally: M.D.	Treated Locally: Clinic	Treated Locally: Total	Total Reported by: M.D.	Total Reported by: Clinic
Under 20,000	884	38.7	17.2	55.9	44.1	0.0	44.1	82.8	17.2
20,000-50,000	949	25.0	21.8	46.8	47.4	5.8	53.2	72.4	27.6
50,000-100,000	456	27.6	18.4	47.0	37.1	16.9	53.0	64.7	35.3
100,000-over	1,510	12.2	9.6	21.8	48.1	30.1	78.2	60.3	39.7
Boston	2,482	2.6	0.0	2.6	42.7	54.7	97.4	45.3	54.7
State	6,281	15.0	9.4	24.6	44.5	30.9	75.4	59.7	40.3

Boston seems to enjoy a position by itself. Although the proportion of cases reported by Boston clinics is too high because of failure of physicians to report, the case rates are all out of proportion to those in other cities of more than 100,000 population. The fact that Boston also has a higher proportion of physicians and clinics than the other communities cannot be the reason, because that would effect only migration into Boston for treatment. There are highly competent physicians and excellent clinics in other cities with lower reported rates.

The attraction of Boston as a medical center is quite remarkable, as shown in the accompanying maps.

Table 6.—*Comparison of Communities with, or Near, Clinics with Those Distant from Clinics*

	Population	Reported Rate Gonorrhea	Per Cent Treated by: Physician	Per Cent Treated by: Clinic
Communities of from [illegible]				
	71,188	102.5	75.3	24.7
	188,591	97.0	74.3	25.7
Far from clinics	180,517	60.7*	99.2*	0.8*
[illegible]				
	139,046	136.7	69.5	30.5
	311,590	148.2	67.1	32.9
Far from clinic	148,957	52.3*	85.9*	14.1*
[illegible]				
	74,541	100.7	76.0	24.0
	311,590	148.3	67.1	32.9
	257,130	102.8	65.9	34.1
	217,492	182.6	60.1	39.9

* Note the low rates and the low clinic population.

Boston physicians see many more of these immigrating patients than do Boston clinics, for although reports indicate an equal distribution, it must be remembered that physicians report much less than half their cases (table 7).

Even clinic cities, of 50,000 and 100,000 population or more, in or close to the Boston Metropolitan Area feel this attraction, patients migrating from them to physicians and clinics in Boston (table 8). The double temptation of local and Boston clinics has not greatly increased the proportion of clinic cases over that in distant clinic cities or in nonclinic cities near Boston (table 6).

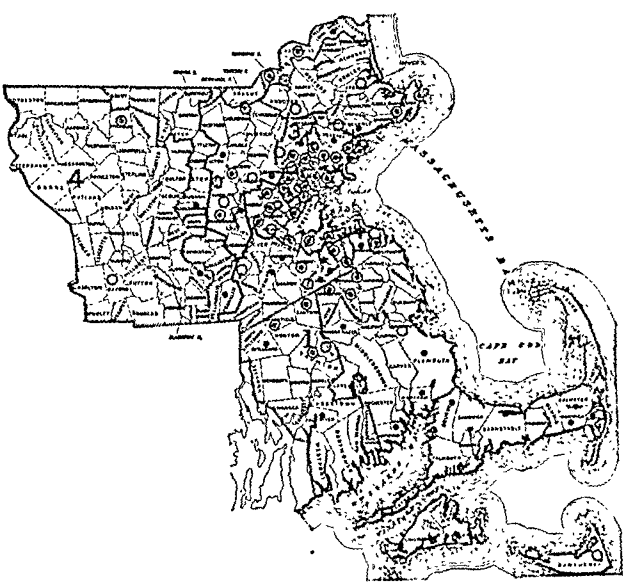

Fig. 1.—Migration of patients to Boston clinics in 1930. Circles indicate gonorrhea (467 cases from sixty-one communities); dots indicate syphilis (400 cases from seventy-six communities). One case of gonorrhea from the western part of the state is not shown.

The twenty communities in the Boston Health District provided 80.1 per cent of the patients with gonorrhea migrating to Boston clinics and 76.7 per cent of those migrating to Boston physicians.

Table 7.—*Migration to Boston Clinics and Physicians Compared with Remainder of State*

Reported by	Cases of Gonorrhea	Per Cent of Total Migration	Number of Communities
Boston clinics.................... ..	467	30.3	61
Boston physicians.........	459	29.8	65
Other clinics (14 cities)...........	122	7.9	57
Other physicians (95 cities).......	495	32.0	158

Very little difference is shown between the migration of male and female patients (23.9 per cent male and 26.9 per cent female), but 10 per cent more of the females than of the males were reported by clinics. Clinics do not provide more secrecy than the physician's office, so that some other reason must be found to explain this apparent greater "preference" for clinics. It may be partly economic, the incomes of working women probably being less than those of men; and it may be due partly to better diagnostic effort in the clinic than in the physician's office. Evidence in support of the latter factor is available:

The ratio of total male to female reported cases is 3.39 to 1. The ratio of male to female cases reported by clinics is 2.55 to 1. That for cases reported by physicians is 4.23 to 1. The common acceptance by physicians of a single negative smear as proof of freedom from infection accounts for much of their failure to make the diagnosis. Male gonorrhea is much more quickly suspected and diagnosed clinically.

THE MIGRATION OF PATIENTS WITH SYPHILIS

Table 9 (to be compared with table 5) offers striking evidence of the difference between gonorrhea and syphilis as medical and economic problems.

Strangely, the proportion of total migration for syphilis (24.9 per cent) is almost exactly the same as that for gonorrhea (24.6 per cent), but it is much higher for syphilis in the two groups of smaller communities. More patients migrate to clinics than to physicians; the proportion of cases reported by local physicians is half that for gonorrhea, and the total cases reported by clinics is more than twice that reported by physicians, local and foreign.

Table 8.—*Migration of Patients with Gonorrhea from Clinic Cities Near Boston* *

Migration to			Treated Locally by			Treated by	
M.D.	Clinic	Total	M.D.	Clinic	Total	M.D.	Clinic
31.9	22.8	54.7	30.8	14.5	45.3	62.7†	37.3†

* Quincy, Newton, Lynn, Cambridge: 532 cases.
† Note agreement with clinic or near clinic cities, table 6.

Probably no single factor nor easily evaluated combination of factors can account for this so different situation with syphilis. Among those to be considered are the following:

1. Fewer physicians treat syphilis than treat gonorrhea, and patients in the smaller communities must go to those cities where physicians who treat syphilis are to be found.

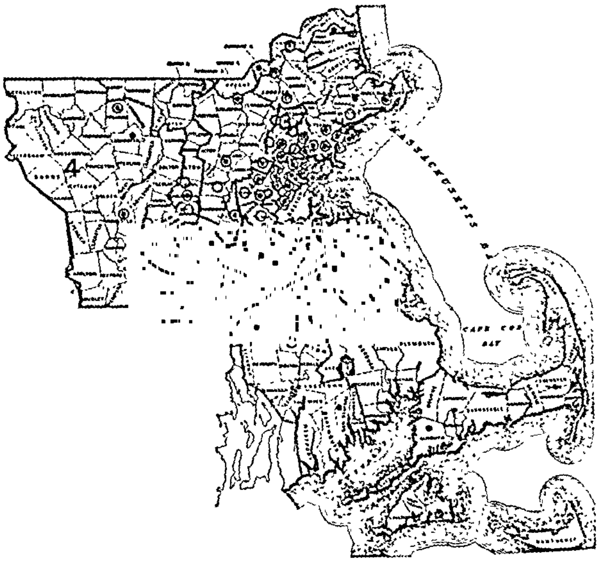

Fig. 2.—Migration of patients to Boston physicians in 1930. Circles indicate gonorrhea (459 cases from sixty-five communities); dots indicate syphilis (212 cases from sixty-four communities). Two cases of gonorrhea and three of syphilis from the western part of the state are not shown.

2. In the larger cities, where physicians who treat syphilis and where clinics are available, patients migrate less because they hesitate to add the cost of travel to the already high cost of treatment. Thus increased, unavoidable migration in the small community is balanced by decreased migration in the larger cities.

3. The cost of treating syphilis and the time required for cure is many times that for gonorrhea. Patients who could have afforded treatment by a physician for gonorrhea cannot afford it for syphilis and migrate to clinics, the cost of transportation being less than the physician's fees.

4. With syphilis, considered to be far more serious than gonorrhea, the patient is more anxious to have expert treatment. Physicians who specialize in the treatment of syphilis are rare outside the larger cities. When the patient has paid his fare to the distant city, he cannot so often afford a physician and goes to a clinic.

5. Syphilis is more likely to involve more members of a family than is gonorrhea and requires more expensive treatment for a longer time, so that the total cost of family medical care is very great. Also, since two thirds of the cases of syphilis that come to medical care are in the late stages, complications are frequent (neurosyphilis, cardiovascular disease, eye involvement, surgical complications). These require even greater specialization, which is proportionately more expensive. Consequently the patient turns to the clinic.

Certainly, however, as with gonorrhea, some of this "preference" for clinics is more apparent than real, for clinics report their cases and many physicians do not.

TABLE 9.—*Migration of Patients with Syphilis (Percentage of Total)*

Size of Community	Total Cases	Migrated to			Treated Locally by			Total Reported by	
		M.D.	Clinic	Total	M.D.	Clinic	Total	M.D.	Clinic
Under 20,000	416	29.6	52.9	82.5	17.5	0.0	17.5	47.1	52.9
20,000-50,000	392	23.5	41.3	64.8	24.7	10.5	35.2	48.2	51.8
50,000-100,000	265	18.5	25.3	43.8	18.9	37.3	56.2	37.3	62.7
100,000-over	836	7.1	13.1	20.2	29.1	50.7	79.8	36.2	53.8
Boston	1,662	0.5	0.0	0.5	20.2	79.3	99.5	20.7	79.3
State	3,571	9.3	15.6	24.9	22.4	52.7	75.1	31.7	68.3

Availability of a clinic has much the same effect on the reported rate of syphilis as it has on that for gonorrhea (table 10, to be compared with table 6). The figures being smaller, there is more statistical error in table 10 than in table 6. But the rates in communities distant from clinics is still so low as to be significant.

The attraction of Boston as a medical center is even more marked than it is for gonorrhea. Boston clinics report nearly twice as many out of town cases as Boston physicians do, but it must again be remembered that physicians often fail to report (table 11, to be compared with table 7).

Clinic cities in or close to the Boston area feel this attraction as they do in the case of gonorrhea (table 12, to be compared with table 8).

The twenty communities in the Boston Health District provided 73.8 per cent of the patients with syphilis migrating to Boston clinics and 65.1 per cent of those migrating to Boston physicians.

Less difference is noted between the migration of the sexes than was noted for gonorrhea (24.3 per cent of males and 25.9 per cent of females). Also, 2 per cent instead of 10 per cent more of the females than of the males were reported by clinics. That the failure of physicians to diagnose female gonorrhea accounts for the difference between the sexes in that disease seems more evident on examining the evidence for syphilis. The ratio of total male to female cases reported is 1.43 to 1. The ratio of male to female cases reported by clinics is 1.39 to 1. That for cases reported by physicians is 1.55 to 1. The Wassermann test is equally available for confirmation of diagnosis of syphilis in the two sexes. There is no sufficiently certain laboratory test for gonorrhea and that disease is much more frequently suspected and diagnosed on clinical observations in the male than in the female.

TABLE 10.—*Comparison of Communities with or Near Clinics with Those Distant from Clinics*

* Note the low rates and the low clinic population.

SUMMARY AND CONCLUSIONS

There are 5,800 physicians practicing among 4,250,000 people in 355 cities and towns in Massachusetts. More than half of these physicians are located in twenty-one communities in the Boston Metropolitan Health District, although only 39 per cent of the population lives there. From unpublished studies it appears that more than half the 5,800 physicians treat gonorrhea and nearly half of them treat syphilis, but only 15 per cent reported gonorrhea and 8 per cent reported syphilis in 1930. A higher proportion of physicians report gonorrhea from the smaller communities than from the larger, but the reverse is true of syphilis. Almost half the reported cases are distributed among 10 per cent of the physicians reporting, and apparently less than 2 per cent of the physicians in the state classify themselves as specialists in the management of these diseases. The twenty-nine clinics in the state are reasonably available to at least 75 per cent of the

* Quincy, Newton, Lynn, Cambridge: 268 cases.
† Compare with table 10.

population and probably to an even greater proportion of the infected population. These clinics report most of the cases they see.

Nearly 45 per cent of the reported cases of gonorrhea and 22 per cent of the cases of syphilis were reported by "local" physicians, no matter how large or how small the community. The reported distribution of cases between physicians and clinics is more apparent than real: The small number of clinic cases in communities distant from clinics is accompanied by low reported case rates, while communities of the same size with or near clinics have high reported case rates. Since clinics report most of their cases and physicians do not, there is a disproportion in clinic cities, or those near clinics, between clinic cases and those reported by physicians.

Boston has a disproportionately high reported rate for both gonorrhea and syphilis. The attraction that Boston has as a medical center is striking, 60 per cent of the migrating patients with gonorrhea and 69 per cent of the migrating patients with syphilis having gone to that city for treatment, most of them, however, from cities in the Boston Health District.

There is little difference between male and female migration in either disease. Apparently a higher proportion of females with gonorrhea are reported from clinics, but there is evidence that this apparent difference is not real but due to failure of physicians to discover female gonorrhea. No such striking difference is noted between the sexes in syphilis.

It may be concluded that:

1. Migration for secrecy is not as great a factor as has been assumed, since an almost constant proportion of the cases are treated by local physicians in communities of all sizes. The lower percentage for syphilis may be explained on the basis of fewer specialists, greater cost of treatment, longer time required for cure, serious complications, and the general feeling that syphilis is more serious than gonorrhea.

2. Clinics apparently are not seriously taking cases away from physicians, for when there are no clinics available the reported rates of both gonorrhea and syphilis are only half as high as the rates in communities of the same size with, or near, clinics.

3. There is no real difference between migration of the two sexes or their choice between clinic and physician, the apparent difference in the case of gonorrhea being due to failure on the part of the physician to discover female gonorrhea.

4. A large medical center has a marked influence on migration of patients with either disease, but a greater one in the case of syphilis. This influence is effective in spite of local clinics and competent physicians or the size of the "home" community.

COMPARISON WITH THE MIGRATION OF PATIENTS WITH TUBERCULOSIS

Of all the common communicable diseases, tuberculosis is the only one, other than gonorrhea and syphilis, that frequently becomes a chronic economic and medical problem. The others, such as diphtheria, scarlet fever, measles and typhoid, are usually managed by the family physician; the cost of their care is relatively small and does not drain the family pocketbook over months or years. Specialized medical consultation is rarely required and there is no object in secrecy.

Tuberculosis, however, is chronic, often difficult to diagnose, requires expensive laboratory study, and is a serious economic problem to many people. The old public horror of the disease is not entirely dissipated, so that some patients still seek to keep their infections from being known.

Unfortunately, the reports for tuberculosis are so lacking in certain details that comparable analysis cannot be made of as many factors as was possible for gonorrhea and syphilis. For instance, it is impossible to determine which of the cases reported by municipal and county sanatoriums and other hospitals are clinic cases or institutional cases. In many instances it was impossible to determine whether a physician saw a patient in his private office or in the clinic of which he was a staff member. Thus 43.1 per cent of the 5,283 cases reported in 1930 could not be classified between clinic and physician or between voluntary migration to a clinic and final hospitalization.

Table 13.—*Migration of Patients with Tuberculosis (Percentage of Total)*

Size of Community	Migrated to			Reported Locally by			Reported by	
	M.D.	Clinic	Total	M.D.	Clinic	Total	M.D.	Clinic
Under 20,000......	23.2	16.6	39.8	58.1	2.1	60.2	81.3	18.7
20,000-50,000......	14.8	15.7	30.5	57.0	12.5	69.5	71.8	28.2
50,000-100,000......	11.8	16.3	28.1	55.6	16.3	71.9	67.4	32.6
100,000-over......	5.3	9.1	14.4	58.3	27.3	85.6	63.6	36.4
Boston...........	1.5	1.1	2.6	29.3	68.1	97.4	30.8	69.2
State...........	8.7	9.5	18.2	48.5	33.3	81.8	57.2	42.8

However, those reports which could be accepted as giving clear information indicate that there is much the same situation with tuberculosis as with gonorrhea and syphilis. Since most of the indefinite reports were from institutions that have associated diagnostic clinics, the figures for clinics in the following analysis are undoubtedly much too low.

There is no information available as to the proportion of physicians treating tuberculosis or specializing in its treatment. Nor have we felt that a study of the number of physicians reporting could be made without more effort than the accuracy of the results would warrant.

There is little difference between migration of the two sexes, but a higher proportion of the males than of the females appear to have been reported by clinics (45.7 per cent of males and 39.4 per cent of females).

In the state as a whole, 81.8 per cent of the patients were reported by local physicians and clinics as compared to 74.4 per cent of gonorrhea cases and 75.1 per cent of syphilis cases. Closer agreement, no doubt, would have resulted if the unidentified sanatorium clinic cases (mostly migrating cases) could have been included.

Clinics reported 42.8 per cent of the cases, as compared to 68.3 per cent for syphilis and 40.3 per cent for gonorrhea. For the reason just given, this figure is again probably too low.

The same apparent increase in clinic cases with increase in the size of the community is noted as in the other two diseases, but, owing to the impossibility of identifying many clinic cases, it is felt that nothing could be gained by comparing reported rates through the comparison of clinic cities with nonclinic cities distant from clinics.

Tuberculosis clinics are much more available than clinics for the treatment of gonorrhea or syphilis, there being fifty-eight municipal clinics in addition to the diagnostic clinics associated with the four state sanatoriums and others associated with the various county sanatoriums. Consequently, migration to another city to reach a clinic occurs less frequently.

Patients also are more likely to go to their family physician for a "cold in the chest" than for a suspicious infection of the genito-urinary tract, which may have some bearing on the high percentage of cases reported by local physicians (48.5 per cent, as compared to 44.5 per cent for gonorrhea and 22.4 per cent for syphilis).

Further, what becomes of the patient after a diagnosis is made is important. Probably the reporting physician turns many cases of tuberculosis over to an institution for treatment, whereas most physicians treat the gonorrhea and syphilis that they discover. Consequently, choice between a clinic and a physician for reason of cost of treatment may be necessary much less frequently in tuberculosis than in gonorrhea or syphilis.

Boston, as a medical center, has a similar attraction in tuberculosis to that in gonorrhea or syphilis, 51.3 per cent of the 546 migrating cases having been reported from that city. Boston clinics reported 75 per cent of these and Boston physicians 25 per cent (table 13, to be compared with tables 5 and 9).

IOPAX

AN ANALYSIS OF THE RESULTS OBTAINED IN FORTY-FIVE CASES, WITH REPORT OF A CASE SHOWING A SEVERE REACTION FOLLOWING INJECTION OF IOPAX *

JAMES J. JOELSON, M.D.
AND
ROBERT ZOLLINGER, M.D.
CLEVELAND

With the introduction of a satisfactory drug for intravenous pyelography, Swick and von Lichtenberg made a valuable addition to diagnostic methods. How useful this method will become, what its disadvantages and dangers may be, and to what extent it will replace some of the older methods will be determined only by a long experience with its use.

The basis for this report is an analysis of the results obtained with iopax (introduced as "Uroselectan") in forty-five cases in which forty-seven injections were done. In all our cases a sterile, freshly prepared 40 per cent solution of iopax was injected directly and slowly into the vein. The usual dose for adults was 40 Gm., although in a few cases in which there was poor renal function or in which this amount had not given the desired results, larger doses were used. In children smaller doses were used, usually about 25 Gm. Three roentgenograms of the urinary tract were then taken as a routine; the first, fifteen minutes after the injection of the drug; the second, forty-five minutes after the injection, and the third, one hour and fifteen minutes after the injection. In many cases in which these routine three exposures did not give the desired results, further roentgenograms were taken at intervals of one-half hour for several additional hours. In a large percentage of the cases, retrograde pyelography was also carried out.

The cases and results obtained with iopax are briefly summarized in the accompanying tables.

Table 1 deals with six cases of pyelitis. In half of these cases complete bilateral pyelograms were obtained with iopax, and in five of the cases diagnostic pyelograms were obtained. The first four cases represent typical instances of pyelitis of childhood, and in these patients uniformly good results were secured. This may be explained by the relatively larger doses used in children, as compared with the adult dose of 40 Gm.

The cases of renal tuberculosis are summarized in table 2. Our results in this type of renal lesion were disappointing, for in only one of the four cases were diagnostic pyelograms obtained, although in none of them was there sufficient renal destruction to account for this failure. In one of his addresses on the subject of intravenous pyelography, von Lichtenberg prophesied that, in the future, cystoscopy would rarely be used in the diagnosis of renal tuberculosis and that it would be necessary only to demonstrate the tubercle bacilli in the urine from the bladder, for injections of iopax would demonstrate the lesion in the kidney. Our meager experience does not bear out this hope, for not only did iopax fail to give the desired results in three of our four cases of renal tuberculosis, but in studying our other intravenous pyelograms we were struck with the frequency with which the minor calices were not properly visualized, and such visualization is necessary for the early pyelographic diagnosis of renal tuberculosis. Furthermore, cystoscopy is still our only reliable means of determining the function of the individual kidney, for this cannot be accurately gaged by iopax, since it not infrequently happens that a normal kidney shows a poor pyelogram with this method.

In table 3 we have grouped our cases of renal and ureteral calculi. There were four of these cases, and in three, excellent results were obtained with iopax. In all three cases, definite obstruction was present, a condition that has been recognized as an aid in obtaining satisfactory results with intravenous pyelography. In case 11 a large stone which obstructed the ureteropelvic junction prevented a retrograde pyelogram, and the marked degree of hydronephrosis was determined only by means of the iopax pyelograms.

Table 4 presents our cases of obstruction of the upper urinary tract. Usually the various forms of ureteral obstruction tend to improve intravenous pyelograms, but this did not appear to be so in our cases. Only in case 21 were the results satisfactory, and here the pyelograms of both kidneys were excellent and a marked kinking of the right ureter was beautifully demonstrated.

Seven cases presenting various types of obstruction of the vesical neck, including the so-called neurogenic bladder, are summarized in table 5. On the whole, our results in this group of cases were not satisfactory. Renal damage undoubtedly accounted for some of the failures, but in most of the cases the renal function tests did not demonstrate severe degrees of renal damage. Furthermore, in four of the injections, doses greater than the usual dose were used. In the two cases of congenital obstruction of the vesical neck (cases 27 and 28), the results obtained were disappointing. In one case a complete pyelogram was obtained on one side with a dose of 40 Gm.; in the other case (case 28) the results were completely unsatisfactory, although renal function tests and retrograde pyelograms demonstrated the absence of any marked renal damage.

In our small group of congenital anomalies of the kidneys (table 6), uniformly good results were seen,

---

* From the Department of Surgery, the Lakeside Hospital.

and we found intravenous pyelography a definite aid in diagnosis. In two of the cases a double pelvis and ureter were suspected from the retrograde pyelograms of one of the pelves, but in neither case could the second ureter be catheterized.

In case 31 a very severe reaction followed the injection of the drug, and for this reason a more complete case report is given here:

A man, aged 55, was sent to the hospital by the industrial commission for complete urologic investigation. One year and four months before admission to the hospital, he fell from a height, striking and injuring the left lumbar region. Immediately following this injury he had hematuria for a short period and then was troubled with frequency of urination. One month after the accident, acute retention of urine developed, for which he was admitted to another hospital. A benign hypertrophy of the prostate was found, and this obstruction was later relieved by a suprapubic prostatectomy. Since this operation, the patient had been troubled with frequency, nocturia, and occasional questionable hematuria. In addition to this he had had constant indefinite pain in the back.

The patient was well nourished and healthy. The temperature, pulse and respirations were normal. The heart and lungs were normal. The blood pressure was 145 systolic and 110 diastolic. Abdominal examination did not reveal any abnormal conditions. Rectal examination gave negative results.

Laboratory examination revealed: red blood cells, 4,800,000; hemoglobin, 90 per cent; white blood cells, 6,400; blood Wassermann reaction, negative; blood urea, 35 mg. per hundred cubic centimeters; phenolsulphonphthalein, 40 per cent excreted in two hours and ten minutes. The Mosenthal test showed normal variation of specific gravity. The urine was hazy and acid; the tests for albumin and sugar were negative. Microscopic examination revealed a moderate number of white blood cells, but no red blood cells or casts.

On cystoscopic examination the bladder was found to be entirely normal except for a mild degree of generalized cystitis. The cystoscope was easily introduced into the bladder, and no obstruction was met in the urethra. The vesical neck did not show obstructive lesions of any sort. The right ureteral orifice appeared normal and was easily catheterized. Two ureteral orifices were seen on the left side, but only the anterior one could be catheterized. The bladder urine was found to contain a moderate number of white blood cells but no red blood cells. The urine from the right kidney was completely normal. The urine obtained from the upper left renal pelvis (lower ureteral orifice) showed an occasional white blood cell. A divided renal function test (1 cc. of phenolsulphonphthalein intravenously) showed a good function on both sides. Retrograde pyelograms were made, and these demonstrated a normal pelvis on the right and a small upper pelvis of a double kidney on the left side. Following this cystoscopic examination, the patient had no reaction, and the temperature and respirations remained normal. On the following day, at noon, 40 Gm. of iopax was injected directly into the vein as a freshly prepared 40 per cent sterile solution. The pyelograms that were obtained were satisfactory and definitely showed a double pelvis on the left side but no other pathologic condition.

A few hours after injection of the iopax, the patient's temperature suddenly rose to 40 C. (104 F.), the pulse rose to 112, respirations became rapid and labored, and the patient felt very sick. He appeared flushed, hot and acutely ill. The

† The four columns under the main heading of "Pyelograms" show the results obtained after the injection of iopax. The right and the left pyelograms are listed separately in order to record the kind of pyelogram obtained in the normal kidney in cases in which the lesion was unilateral. The results are tabulated as "negative" or "positive." A pyelogram was considered as "complete" only when both the pelvis and the minor calices were distinctly outlined. The outlining of the ureter was not considered, since a satisfactory ureterogram was obtained in only a few of our cases. A pyelogram was considered "diagnostic" when it gave sufficient information to be of diagnostic value in the specific case, even though the pyelogram was not perfect.

leukocyte count increased to 14,800, but there was no change in the urinary observations. The throat showed a very mild degree of congestion. Examination of the chest, which had been normal previously, now showed numerous moist and crackling râles scattered throughout both lungs but most marked at the right base. There was no change, however, in the percussion note or voice sounds, and expansion was equal on the two sides. The heart was normal although rapid. The abdominal examination was negative, and there was no tenderness in either renal region.

The patient was extremely ill for about sixty hours; during this time the temperature remained high, and then it gradually began to come down, reaching normal on the fifth day, as shown in the accompanying chart. The pulmonary signs, which never became more marked than those described, gradually began to disappear after several days, and had entirely disappeared by the fifth day. The sputum during the acute course of the disease was thin and mucoid with occasional streaks of purulent material. Microscopically it showed numerous polymorphonuclear leukocytes but no erythrocytes.

Although this patient recovered completely from this reaction and apparently was not permanently injured by it, still, during the early course of the disease he appeared to be an extremely sick man and we were greatly alarmed about his condition.

Table 7 shows the results obtained in our two cases of renal tumor. In one case excellent results were obtained, whereas in the other case no pyelographic shadows whatever were seen in the roentgenograms.

Table 8 shows the good results that we obtained in our two cases of nephroptosis. The method seems desirable in this type of case, for, when the pyelograms are taken in the upright position, the ureter is not kept rigid by a catheter, thus allowing the ureteral kinks and the degree of ptosis to be clearly demonstrated.

In two cases of carcinoma of the bladder (table 9), we attempted to determine the condition of the upper urinary tract by means of intravenous pyelography. The pyelograms obtained showed a moderate degree of hydronephrosis. In one case, however, no pyelogram was obtained on the right side. Satisfactory cystograms were obtained in both cases.

Table 10 represents a group of miscellaneous cases in which varied results were obtained.

Case 41 is of especial interest. This patient sustained an injury to the left kidney, which resulted in marked hematuria. Two injections of iopax were done, the first on the day following the injury and the second, seventeen days later. Neither time could any shadow

While our series of forty-five cases is much too small to allow any final conclusions to be drawn, certain preliminary conclusions and indications for the use of iopax seem evident.

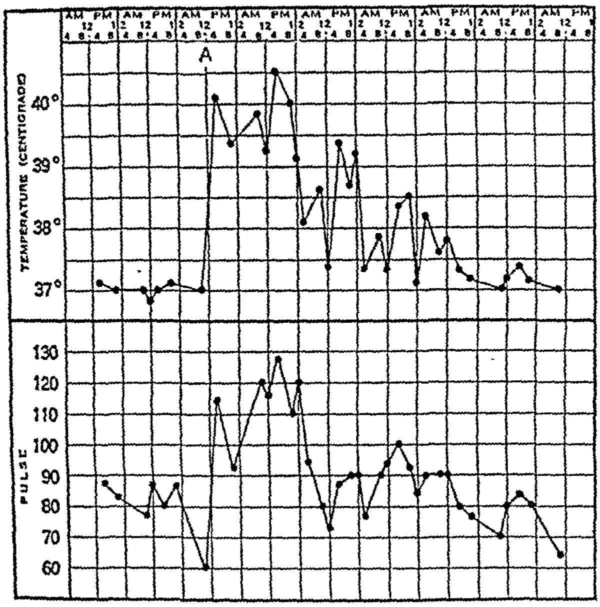
In certain types of cases the method has definite value. In pyelitis of childhood, for example, it gave such consistently good results that it probably should always be used before attempting cystoscopy. A common problem in children is the differentiation between a simple pyelitis and an infection of the urinary tract superimposed on some form of congenital obstruction. It is in these obstructive conditions that an early diagnosis is essential, for severe renal damage may occur while the child is being treated for a simple pyelitis. In the majority of these cases intravenous pyelography will probably give the necessary information (absence or presence of hydronephrosis) and thus obviate the necessity of a cystoscopic examination.

Good results were also obtained in cases of urinary lithiasis, congenital anomalies of the kidneys, and nephroptosis. Our results in the cases of obstruction of the upper urinary tract were not good, but it is likely that better results will be found in a larger group of these cases. Only two renal tumors occurred in our series, but excellent pyelograms were obtained in one case. Our number of vesical tumors is also too small to permit any conclusions, but the results were encouraging.

When the figures for the entire series of cases are examined, however, they are somewhat disappointing, for complete pyelograms were obtained in only about 40 per cent of the cases and diagnostic results in only 51 per cent. Doses of iopax reaching as high as from 60 to 80 Gm. have been recommended for routine use by some investigators, in order that satisfactory pyelograms may be more uniformly obtained. We have hesitated to follow this suggestion because of the frequency with which mild reactions were observed after the injection of only 40 Gm. of the drug. Mild reactions, such as nausea, vomiting, sensation of warmth, pallor, and pain in the arm, occurred in over 55 per cent of our cases. Furthermore, the case in which the severe reaction resulted (case 31) occurred fairly early in our series and made us timid about using larger doses.

An objection that may well be raised to the use of iopax is the expensiveness of the method, for not only are the necessary repeated roentgenograms costly but the drug itself is expensive. When the total cost of the method is compared with only a 50 per cent chance of obtaining any diagnostic information, one hesitates to use the method as a routine in all cases requiring urologic investigation.

Our present impressions concerning intravenous pyelography by means of iopax may be briefly stated as follows: Although the method is undoubtedly a valuable addition to our other methods of diagnosis, it cannot be expected to give consistently good results. In certain selected types of cases it should be used as a routine, whereas in other cases it should be used only when the older methods fail. It is very unlikely that it will ever replace cystoscopy and retrograde pyelography. Larger doses will no doubt tend to give better results, but until sufficient evidence has been collected to show that the drug is nontoxic, a conservative attitude should be maintained concerning this point.



Temperature (upper curve) and pulse (lower curve) in case 31: *A*, injection of iopax.

SUMMARY

An analysis was made of the results obtained with iopax in forty-five cases.

Diagnostic pyelograms were obtained in only 51 per cent of the cases, and completely satisfactory pyelograms in about 40 per cent of the cases.

The best results were obtained in pyelitis of childhood, urinary lithiasis, congenital anomalies of the kidneys, and nephroptosis. Iopax was not satisfactory in our cases of renal tuberculosis.

One of the main deficiencies of the method was that the minor calices were frequently not visualized at all or were incompletely visualized.

The drug may not be entirely nontoxic, as evidenced by frequent mild reactions and one severe reaction.

The method is expensive, and this becomes a valid objection to its routine use when one considers the frequency with which unsatisfactory results occur.

THE PATHOLOGIC BASIS OF SYMPTOMS IN NEPHRITIS *

J. P. SIMONDS, M.D.
CHICAGO

Any attempt at classification of nephritis should take into consideration the following facts: 1. The kidneys are very complex organs composed of about two million physiologic units, each of which is itself a complex structure. 2. The various parts of each physiologic unit are so interrelated and coordinated that serious changes in one part are followed by correlated changes in other parts of the unit. 3. The noxious agents which cause damage to the kidneys are probably multiple in kind, vary in degree of injuriousness, and may act either intermittently, remittently or continuously. 4. The number of types of relatively simple pathologic unit lesions that may be produced in the kidneys by these noxious agents is great. 5. The blood supply of the kidneys is very abundant, and primary changes limited entirely to the blood vessels may induce grave alterations in renal structure and function. 6. Nephritis is not a static condition, but both clinical and anatomic pictures change with the progress of the disease. 7. Effective elimination of waste products by the kidneys depends on a blood flow and blood pressure in the glomeruli adequate to maintain an effective filtration pressure within the glomerular capillaries. 8. The number of mathematically and biologically possible combinations of the foregoing variables makes any too detailed classification of nephritis an almost hopeless and probably a fruitless task.[1]

Two main types of nephritis can be readily differentiated: (1) that in which the secretory portion of the kidneys is primarily damaged and (2) that in which the primary lesion is in the smaller arteries and arterioles. For clinical and even for more scientific purposes such a simple classification meets the essential requirements. More elaborate classifications are likely to be confusing because they attempt to make separate types and clinical and pathologic entities out of (*a*) different stages of the same morbid process or (*b*) different combinations of the same fundamental unit pathologic lesions.

This simple but comprehensive classification is justified by two facts: 1. The basic pathologic changes are distinctly different in the two types. 2. These structural alterations have fundamentally different effects on renal function. Cases in the first group may be either acute, subacute or chronic, and have been variously termed parenchymatous nephritis, glomerulonephritis, and nephrosis. The basic pathologic process common to all these forms is degeneration with inflammation of varying degrees of intensity; the fundamental functional change is an increased permeability of the renal filter. The second group is essentially chronic and includes cases generally classed as chronic interstitial nephritis and primary, genuine or arteriolosclerotic contracted kidneys. The underlying pathologic process is a diffuse hyperplastic sclerosis of the smaller branches of the renal arteries, especially the afferent vessels to the glomeruli. The effect of this change is a reduction in blood flow and blood pressure, and therefore of effective filtration pressure, in the glomeruli, with resultant inadequate excretion of waste products.

---

* From the Department of Pathology, Northwestern University Medical School.

[1] Simonds, J. P.: The Problem of Classification of Nephritis, J. A. M. A. **95**: 930 (Sept. 27) 1930.

In the first of the two aforementioned broad groups the secretory apparatus of the kidney is damaged. The kidneys themselves are swollen and larger than normal and, in the acute and subacute forms, the surface after the capsule has been stripped off is relatively smooth, the cortex is increased in thickness, and the normal cortical markings are indistinct and irregular. Microscopically, there are various types of alterations in glomeruli and retrogressive changes in the tubular epithelium.[1] As the disease progresses and becomes chronic, more and more physiologic units are destroyed and are replaced by fibrous tissue, the surface becomes pitted with small scars, and the cortex shows irregularities in thickness. The glomeruli suffer serious change, even in nephrosis, as shown by Bell.[2] The blood flow through the glomerular capillaries may or may not be interfered with as a result of thrombosis or of swelling or proliferation of the lining endothelium. When, as in lipoid nephrosis, the capillaries are only partially obstructed so that they continue to function, atrophy of the tubules does not occur. The most important functional alteration in this type is an increased permeability of the glomeruli due to alterations in the lining endothelium, damage to the basement membrane and retrogressive changes in the covering epithelium. This explains the absence of retention of waste products and the presence of albumin and even blood in the urine. In spite of the partial disturbance in glomerular blood flow, the increased permeability permits the adequate elimination of waste products. The available filtration pressure within the hyperpermeable glomeruli is adequate for proper functioning of the mechanism.

The increased permeability of the glomeruli in the first type of nephritis permits the escape of albumin in the urine. The lymph which escapes through the capillary walls of all organs contains albumin. There are only three locations in the body in which albumin does not normally escape through the capillary wall; namely, in the glomeruli of the kidneys, in the alveolar walls of the lungs and in the choroid plexus of the brain. In each of these locations the capillary endothelium is covered on its outer surface by a layer of closely adherent flat epithelium. In the glomeruli, at least, as shown by McGregor,[3] these are separated by a thin hyaline basement membrane. Epithelium is normally impermeable to colloidal solutions. It appears probable, therefore, that the presence of albuminuria in the first type of nephritis (which includes the so-called nephrosis and glomerulonephritis) is due to alterations in the basement membrane and retrogressive changes in the epithelium of the glomeruli rather than to changes in their endothelium.

The edema which is so characteristic of this type depends on (1) depletion of the serum albumin of the blood by its loss in the urine, and (2) the retention of crystalloids in the tissues. Barker and Kirk[4] have shown by a series of unique experiments on dogs and by quantitative studies of serum albumin of the blood of nephritic patients that the reduction of the serum albumin of the blood to 1 per cent or below is followed by the accumulation of fluid in the subcutaneous tissues; i. e., by edema. Fahr, Kerkhof and Conklin[5] found that the normal values for the osmotic pressure of the plasma proteins were from 20 to 23 mm. of mercury and that the osmotic pressure of the plasma proteins was 11 mm. of mercury, or lower in all their cases of nephropathic edema. The retention of crystalloids in the tissues is apparently not due to inability of the kidneys to excrete them but to some other mechanism possibly concerned with an effort to maintain the concentration of the proteins of the blood at their normal level. The accumulation of chlorides in the tissues increases the osmotic pressure of the tissue fluids, and this, in turn, leads to the withdrawal of water from the blood, causing concentration of serum albumin in the blood and increasing the fluid content of the tissues, inducing edema.

The presence of large amounts of albumin in the urine together with products of disintegration of the tubular epithelium, which is the seat of various retrogressive changes, furnishes material for the formation of the casts which are a characteristic observation in this type of nephritis. The presence of albumin is also a factor in the increased specific gravity of the urine in this disease.

All forms of this type of nephritis, whether they are called nephrosis, glomerulonephritis or parenchymatous nephritis, show the aforementioned characteristics (exudation, degeneration and increased glomerular permeability) in varying degree throughout the course of the disease. The progressive destruction of physiologic units in very chronic cases may finally result in such a reduction in available glomerular filtration surface that an increase in systemic blood pressure becomes necessary in order to supply a filtration pressure adequate to proper elimination of waste products. Thus, increased blood pressure, not a part of the disease per se, may appear late in the course of this type of nephritis, perhaps as a compensatory mechanism.

In the second or vascular type, conditions are quite different. The glomeruli are not primarily injured, and the filtration apparatus is not rendered more permeable. So far as the glomeruli are concerned, the function of filtering urine from the blood proceeds more or less normally until secondary changes occur in the glomeruli. The primary change in this type is in the smaller arteries and arterioles, especially in the afferent vessels to the glomeruli, and consists of a narrowing of their lumens, as a result either of arteriospasm or, more commonly, of a diffuse hyperplastic sclerosis. This change is quite different from the ordinary type of arteriosclerosis (atherosclerosis). The latter is nodular in distribution, involving only a sector of the circumference of the vascular lumen, and consists of a focus of connective tissue hyperplasia, with fatty degeneration and deposit of lipoids, in the intima. This change may materially interfere with the circulation in small arteries and, as a result of a terminal thrombosis, may entirely occlude the vessel, such as a branch of the coronary or the renal artery. Such a result is focal rather than diffuse. In the hyperplastic type, fibrosis without noticeable fatty degeneration occurs throughout the entire circumference of the intima. The lumen is gradually narrowed and is ultimately obliterated and replaced by a core of connective tissue. This change is not limited to the renal arterioles. In cases of this type of nephritis I have seen it in the smaller arteries and arterioles of the spleen, pancreas and liver, and in the suprarenals and surrounding fat. It has also been observed by Kernohan, Anderson and Keith[6] in the arterioles of skeletal muscles. This second type of

"nephritis" is, therefore, essentially a generalized disease of the arterioles of the body and is not primarily a disease of the kidneys. The occurrence of this change in the arterioles of the kidneys affects renal function and ultimately causes death from uremia if this termination does not occur earlier in the course of the disease from cerebral hemorrhage, decompensation of the hypertrophied heart, or intercurrent infection.

Arteriosclerotic contracted kidneys, unlike the arteriolosclerotic form, may show little or no functional disturbance in spite of the large areas of replacement fibrosis (scars). This is because the vascular changes are focal rather than diffuse. Between the scars enough renal tissue remains with sufficient blood supply for efficient functioning.

The secretion of urine depends on (1) the blood pressure and (2) the rate and volume of blood flow, in the glomerular capillaries. In order to maintain a pressure and blood flow adequate to the normal secretion of urine in the presence of this diffuse hyperplastic arteriolosclerosis, an increase of systemic blood pressure is necessary. This is characteristically the first symptom to manifest itself in this form of the disease. This increased systemic blood pressure at first compensates for the narrowing of the arterioles, and the normal glomeruli receive enough blood under sufficient pressure to excrete the normal waste products of the body. Later, glomeruli are progressively destroyed or rendered incapable of functioning as a result of either (1) the extension of the sclerosing process from the afferent arterioles into the glomerular capillaries or (2) complete occlusion of the afferent vessel by thrombosis or obliterating endarteritis.

The factor of safety of the kidneys is high; i. e., there is four or five times as much kidney substance as is actually necessary to perform adequately the function of these organs. Or, stated differently, three fourths of the total normal kidney substance may be removed without the animal showing any signs of renal insufficiency. Hence a very extensive destruction of glomeruli and their tubules may occur without evidence of renal insufficiency, provided an adequate blood pressure and blood flow are maintained in the remaining intact glomeruli. In this type of nephritis, retention of waste products is not due to primary deficiency in function of the glomeruli but to their failure to receive sufficient blood under adequate pressure to enable them to act as efficient filters. The increased systemic blood pressure is a compensatory mechanism which may, for a time, enable the kidneys to perform their function in a satisfactory manner but may at the same time endanger life by its effect on other organs, especially the brain.

Schapiro has shown, by injecting kidneys which were the seat of this type of disease, that only a part of the capillary loops were open in a glomerulus whose afferent vessel was markedly narrowed. This may be a further compensatory mechanism. If the narrowed artery cannot deliver enough blood to maintain the necessary blood pressure and blood flow in its whole glomerulus, it may be able to maintain these necessary conditions in a part of the glomerulus, so that this structure is not rendered entirely functionless.

The work of Richards[7] and his students has furnished more definite proof of an older view that the glomeruli are merely filters through which passes a fluid containing urea, chlorides and other waste products in the same concentration as that in which they are present in the blood and that the urine is concentrated in the tubules as a result of the action on the tubular epithelium by the absorption of water. In this vascular type of nephritis the kidneys are unable to concentrate the urine in the normal manner. The urine is increased in quantity and its specific gravity becomes "fixed" at a low level. The quantity of voided urine is not as great as the estimated amount (100 liters in twenty-four hours)[8] that passes through the glomeruli of normal kidneys, and it contains urea and other waste products in greater concentration than they are present in the blood but not in as great concentration as they occur in normal urine. Hence some ability to concentrate is still possessed by the kidneys in this type of nephritis.

How, then, are we to account for the increased quantity and lowered specific gravity of the urine in this disease? Two factors are probably concerned: (1) atrophy of the tubular epithelium, and (2) diminished blood flow through the plexus of capillaries which surround the tubules and receive their blood from the efferent vessels of the glomeruli. Attention has already been called to the interrelation of the different parts of the complex physiologic unit of the kidney; namely, the afferent vessel, the glomerulus, the capsule of Bowman and the long tortuous tubule to which it gives rise. In this type of nephritis the function of the glomeruli is interfered with, not by primary disease of their structure but as a result of changes in the vessels which supply them with blood. Destruction or partial or complete loss of function of a glomerulus from this cause is followed by atrophy of the tubule that receives its secretion, and atrophic epithelium cannot function normally.

Perhaps of greater importance is the inadequacy of the blood supply to the tubules. The efferent vessel leaves the glomerulus and breaks up into a plexus of capillaries which surrounds the first and functionally most important part of the renal tubule connected with that glomerulus. A glomerulus supplied by a sclerosed and stenosed arteriole receives a diminished quantity of blood, perhaps only enough to fill a part of its capillary loops, as shown by Schapiro. The amount of blood which reaches the peritubular plexus is therefore below normal. This diminished blood supply results in inadequate nutrition of the tubular epithelium which is concerned with the concentration of the urine. Insufficient nutrition leads to atrophy and to diminished function; i. e., incomplete concentration of the urine. Or if, as is held by some, the function of the tubules is not to concentrate urine but actually to excrete the crystalloids of the urine, the effect on renal function of insufficient nutrition due to these vascular changes would be the same in either case; namely, subnormal excretion and, therefore, retention of waste products.

Hence in a case of this vascular type of nephritis of moderate or great severity, two things occur: 1. The glomeruli do not filter out from the blood the total enormous amount of dilute solution of waste products furnished by the glomeruli of normal kidneys. This is due to reduced circulation of blood in the glomerular capillaries because of the narrowed lumens of the arterioles and afferent vessels. The amount of urine separated in the glomeruli, however, probably greatly exceeds the quantity passed from the bladder. Diminished glomerular filtration must be present to account for the accumulation of waste products in the blood. In diabetes insipidus, in which the filtration mechanism is quite efficient, there is no evidence of renal insufficiency in spite of the very high dilution of the urine. 2. As a result of atrophy of the tubular epithelium due to diminished gomerular function and to reduced blood supply to the tubule, the normal concentration of the urine filtered through the glomeruli does not take place.

[7] Richards, A. N.: Kidney Function, Harvey Lectures, 1920, vol. 16.

[8] Cushny, A. R.: The Secretion of Urine, London, 1926.

In this form of nephritis, therefore, increased quantity of voided urine of low specific gravity actually means both decreased glomerular filtration and incomplete concentration in the tubules.

Fixation of specific gravity is a characteristic clinical manifestation of this type of nephritis. It is probably the result of four factors: 1. As a result of the vascular changes and the structural and functional alterations which they entail, the factor of safety of the kidneys is reduced to or below the critical point. 2. As a consequence, these organs are continually functioning at their maximum capacity. 3. They cannot respond to the normal diurnal changes in blood pressure and blood flow which are responsible for the differences in specific gravity of day and night urines of normal persons. 4. There is even the probability that the normal diurnal changes in blood pressure and rate and volume of blood flow through the kidneys may not occur in this type of nephritis because of the constant hypertension.

While most cases of nephritis fall readily into one or the other of these two groups, combined forms may occur. A clear understanding of the basic pathologic changes characteristic of each type and of their influence on renal function should aid in interpreting the clinical manifestations of these mixed forms.

In the treatment of these two types, quite different methods would appear to be rational. In the first type a high protein diet should aid in restoring the depleted serum albumin. Reduction of water intake and of salt in the diet should aid in relieving the edema. In the second type a high protein diet would add to the nitrogenous waste products which the kidneys are already unable adequately to excrete. Normal or abundant water intake might aid in flushing out the accumulated waste products.

SUMMARY

1. Two types of nephritis can be differentiated: (*a*) that in which the essential damage is to the secretory portion of the kidneys, and (*b*) that in which the smaller arteries and arterioles are characteristically involved. This second type is not so much a primary disease of the kidneys as a generalized disease of the arterioles of the body.

2. The basic changes in the first type are degenerative and exudative (inflammatory) resulting in increased permeability of the renal filter without retention of nitrogenous products but with loss of albumin in the urine, depletion of blood serum albumin, retention of crystalloids in the tissues and edema. In the second type the fundamental pathologic change is a hyperplastic sclerosis of the smaller renal arteries and arterioles with narrowing of their lumens, (*a*) reducing blood pressure and blood flow in the glomeruli below that required for adequate filtration and (*b*) interfering with the nutrition and therefore with the function, of the tubules, thus causing retention of nitrogenous waste products.

3. More elaborate classifications are confusing because they attempt to make separate entities and types out of (*a*) different stages of the same morbid process or (*b*) different combinations of the same fundamental unit pathologic lesions.

4. If due recognition is given to the fact that nephritis is a progressive disease, it is possible, by means of this simple classification, to make a reasonably satisfactory correlation between its clinical manifestations and their pathologic basis, and to elaborate the principles of rational treatment.

Clinical Notes, Suggestions and New Instruments

SUBACUTE BACTERIAL ENDOCARDITIS WITH LARGE BRAIN ABSCESS *

MEYER A. RABINOWITZ, M.D.; ISRAEL H. MARCUS, M.D.,
AND JOSEPH WEINSTEIN, M.D., BROOKLYN

But few cases of definite subacute bacterial endocarditis associated with brain abscess have been reported. Zolotowa[1] recently described a case with purulent meningo-encephalitis. Kimmelsteil,[2] in an excellent article on the subject, reports several cases with brain abscesses of very minute or microscopic size. Nathan[3] reports a case with microscopic brain abscesses. Winkelman and Eckel[4] cite a case with multiple small brain abscesses. Nadler and Herndon[5] report a case with a pea-sized purulent area in the internal capsule. Gilmore[6] observed a case with two brain abscesses, each about one-half inch in diameter.[7] Dr. Emanuel Libman, who has seen probably more cases of subacute bacterial endocarditis than any one else in America, advises us that he has never observed a case with a brain abscess.[8]

Because of the rarity of the occurrence of brain abscess in subacute bacterial endocarditis, and because in most cases previously reported the brain abscesses have been small or microscopic, the following case of subacute bacterial endocarditis with large brain abscess is recorded:

History.—H. S., a schoolboy, aged 15, admitted to the Jewish Hospital of Brooklyn, Dec. 6, 1929, whose family history was entirely negative, had had an attack of poliomyelitis at the age of 9. At 13 he had had scarlet fever, following which he suffered from frequent attacks of sore throat, and was admitted to the St. Marks Hospital in New York, where a diagnosis of rheumatic endocarditis was made. He remained in that institution for one month and was then confined to bed at home for a period of eight months. Tonsillectomy was performed at the age of 14. He did not suffer at any time from precordial pain, dyspnea, palpitation on moderate exertion or edema.

Six weeks prior to admission he had begun to have sore throat, headache and an irregular fever, which reached as high as 103 F. Two weeks before admission, for a period of three days, he had complained of soreness of his finger tips. Five days prior to admission there had occurred a complete left sided paralysis, without loss of consciousness. On the day before admission he had passed deep red urine. He had lost 16 pounds (7.3 Kg.) in the six weeks of his illness.

Physical Examination.—The temperature was 104 F. and the pulse 130; respirations were 44. The blood pressure was 132 systolic and 0 diastolic. The patient was thin, pale and emaciated. He appeared acutely ill and lay in bed on his right side with his head turned to the right. Sordes was present on both lips. There were numerous nevi on his body. There were many petechiae in the conjunctivae and over the axillary folds, abdomen and chest; many of these petechiae had white centers. The movements of the eyeballs were normal. Examination of the ear was negative. The tongue was dry. The neck was rigid. Examination of the lung revealed nothing abnormal. The heart was slightly enlarged to the left. On percussion the aorta was not enlarged. There were marked pulsations in the peripheral arteries. The apex beat was diffuse and in the fourth interspace just outside the nipple line. There was a presystolic thrill at the apex. A double murmur was heard over the apex and also over the entire precordium. At the aortic area the second heart sound could not be heard, and the double murmur was especially loud here. The heart beat was regular in rate and force. The abdomen was flat. The spleen was hard, and its edge was felt one finger-breadth below the costal margin. There was tenderness in the left lower quadrant of the abdomen but no spasticity. The liver was not palpable. There was a lower left facial palsy. The tongue protruded to the left. There was difficulty in swallowing. There was a paralysis of the upper and lower extremities on the left side. The knee jerks were weakly present on the left and completely absent on the right side, where there existed a pes cavus due to the old poliomyelitis. There was no Babinski sign nor any of its modifications. Bed sores were developing on the sacrum, the left elbow and the left heel.

[7] *Gilmore: Personal communication to the authors.*

[8] Libman, Emanuel: Personal communication to the authors.

The diagnosis was made of old rheumatic heart disease with mitral stenosis and regurgitation and aortic regurgitation, with subacute bacterial endocarditis engrafted on the old rheumatic endocarditis, and with embolization to the middle cerebral artery on the right side, to the meninges, and possibly also to the intestines. The possibility of a subarachnoid hemorrhage was likewise considered. A spinal tap was done and clear fluid obtained under moderately increased pressure. The fluid showed 30 cells per cubic millimeter, consisting of 10 red blood cells, 15 lymphocytes and 5 polymorphonuclear cells. The culture of the spinal fluid was sterile.

Eyeground examination revealed slight blurring of the margins of the right disk. There was a reddish patch below the disk margin, which was probably a hemorrhage. Slight arterial pulsations were present. No other hemorrhages or exudate in the fundi were seen.

An electrocardiogram showed a ventricular rate of 136 and regular sinus rhythm. P was upright in all leads, slightly slurred in lead I. T was upright in all leads. There was sinus tachycardia.

No histiocytes were found in the blood. The Wassermann and Kahn tests of the blood were negative. All the blood cultures, five in number, were sterile. The red cell count on admission was 4,000,000 with 48 per cent hemoglobin, and before the patient died it had fallen to 2,700,000 with 30 per cent hemoglobin. The white blood cells varied from 17,000 with 92 per cent polymorphonuclears to 30,000 with 89 per cent polymorphonuclears. The urine was normal on admission but later showed occasional red cells and a faint trace of albumin. Chemical examination of the blood gave normal figures.

The patient's temperature usually was between 102 and 104 F., showing usually a daily variation of from 2 to 3 degrees. During his course in the hospital he showed repeated crops of white centered petechiae in the conjunctivae and skin. He was treated with sodium cacodylate intravenously and with transfusions, but his condition showed no improvement and he died, Jan. 7, 1930.

Autopsy.—The brain weighed 1,275 Gm. It was extremely pale. There was a subpial hemorrhage 3 by 4 cm. in extent over the left frontoparietal region. The brain was hardened in solution of formaldehyde and later, on section, was found to contain an abscess with pus cells in the right frontoparietal region. There was a definitely organized membrane wall 3 cm. in diameter surrounding this abscess. Unfortunately, because of the action of the formaldehyde, no culture could be made from this pus. The lungs showed early terminal bronchopneumonia. The heart weighed 300 Gm. The pericardial surface was rough and had a thin fibrinous exudate. The atria appeared normal. On the anterior cusp of the mitral valve was a large pedunculated friable vegetation, mulberry shaped. On the posterior cusp, near the margin, was a verrucose, firm vegetation. On the same cusp on the auricular surface was also a similar vegetation. The whole valve was thicker than normal. The chordae tendineae were of normal thickness and not shortened. There was no stenosis of the orifice. The aortic valve presented some rolling in of the edges, which latter were moderately thickened. The tricuspid and pulmonic valves appeared normal. The endocardium showed no changes. The myocardium was of normal color, size and consistency. The foramen ovale was closed. The stomach and intestines showed nothing abnormal. The liver weighed 1,659 Gm. The capsule was smooth and glistening. The consistency was moderately firm. On section, it presented a yellow brown color and was somewhat congested. Microscopically it showed congestion and cloudy swelling. The gallbladder was normal. The spleen weighed 720 Gm. It was moderately firm in consistency. The capsule had lost its glistening appearance. On the surface were numerous small white plaques and one large reddish area. On section the tissue presented a varied appearance. It was for the most part of a light pink color with the malpighian corpuscles standing out rather prominently. Numerous gray strands ran through it. There was a triangular dark red infarcted area in which were seen numerous small white nodules (old infarcts). The pancreas and suprarenals were normal. The right kidney weighed 150 Gm., the left 117 Gm. Their capsules stripped with some difficulty, leaving a smooth surface. There were numerous small hemorrhages, varying in size. On section the markings were somewhat indistinct. The cortex was of normal thickness. In the left kidney was a white firm nodule just below the surface, probably an old infarct. Microscopically, focal glomerular nephritis and a large area of necrosis was observed. The ureters, bladder and prostate were normal. The bone marrow showed an erythrogenic hyperplasia.

The anatomic diagnosis was thrombo-ulcerative endocarditis, pericarditis, chronic interstitial myocarditis, bronchopneumonia, parenchymatous hepatitis, infarction of the spleen and kidney, focal glomerulonephritis, abscess of the brain, and erythrogenic hyperplasia of the bone marrow.

COMMENT

The case here described is one of subacute bacterial endocarditis with a brain abscess 3 cm. in diameter. It is impossible in the present state of knowledge to declare why in some few cases of subacute bacterial endocarditis a brain abscess has developed. There is the possibility that it may be due to an unrecognized mixed infection. Nathan[3] appears to believe that it may be due to a massive invasion of the bacteria. There is also the possibility that, owing to the relative paucity of phagocytes in the brain,[9] the viridans organisms are here able to infect bland emboli and form abscesses, whereas in the abdominal viscera, where phagocytes are more numerous, they cannot do this. All these are possibilities; but at present there is no evidence in favor of any one of them.

Although we have observed many cases of subacute bacterial endocarditis, we have in no other instance noted such high leukocytosis and polynucleosis. If, therefore, we were again to encounter a case of subacute bacterial endocarditis with suddenly occurring hemiplegia and very high leukocytosis and polynucleosis, and if there were no other suppurative lesion present, we should be very strongly suspicious of the existence of a complicating brain abscess.

The Results of Scientific Investigations.—It has been stated, by some, that science is ruthless, cold and inhuman. Inasmuch as the aim of science is the search for truth, the prosecution of research cannot in its course pay much respect to conventionalities of thought or hold inviolate traditions of any kind. The results of scientific investigations may often oppose and offend current ideas and cherished opinions. Much the same can be said, however, of new methods of expression by great artists. The music of Bach was almost incomprehensible to his generation, and certainly Wagner at first was not accepted with enthusiasm.—Longcope, W. T.: Methods and Medicine, *Bull. Johns Hopkins Hosp.* **50**:4 (Jan.) 1932.

Special Article

CONTRACT PRACTICE*

R. G. LELAND, M.D.
Director, Bureau of Medical Economics, American Medical Association
CHICAGO

Contract practice is not a new development in medical care; it began as an essential feature of many pioneering projects in mining, railroad construction and lumbering; it is now assuming new forms, becoming highly competitive, using unethical methods and involving a large number of physicians.

Ever since men achieved the first stages of civilization, there has been nothing they have refused to do to obtain health when they have been sick. They have been willing to be half drowned, to be buried alive in earth up to their chins, to be pierced with needles and branded with hot irons, to have leeches suck their blood and to swallow vile tasting concoctions—and to pay for all this—in the hope of attaining cure from disease and of regaining health.[1] Now it may be added that many are willing to bargain with the lowest bidder on a contract basis for incomplete and inadequate medical services, and that for only a part of the family, because some solicitor tells them they will receive the best medical care at a ridiculously small sum.

NUCLEUS IS PLANTED FOR CONTRACT PRACTICE

About the middle of the last century, two types of medical practice were developed which were destined to be the forerunners of a dangerous, complicated, commercial medical system. One of these types was the Mutual Benevolent Hospital Association, philanthropic in character, having liberal endowments, extensive hospital properties and hospital staffs of high grade reputable physicians, all organized and maintained for the membership only; the other type was the medical service developed by the railroad, mining and lumbering companies for their workmen employed in places in advance of or apart from communities with medical facilities. The Mutual Benevolent Hospital Associations were organized to provide for their memberships the best obtainable medical services at the most reasonable cost. The mining, railroad and lumbering companies were moved by two factors to provide medical care for their employees: first, because necessary medical services could not be secured otherwise, and, second, to avoid or to minimize the liability that might arise from neglect of medical care and to reduce the loss to the companies in working hours thus affecting production, because of accidents or illness.

The precedent of such plans, developed by the exigency of the situation, the enactment of state workmen's compensation laws and the popular lay revolt against the costs of medical care, are now used as ample justification for the present systems of contract practice. All the contract plans now operating are essentially forms of sickness insurance. A study now being made by the American Dental Association, from which I shall quote briefly, shows how clear is the trend in the field of contract practice toward sickness insurance:

> Workmen's compensation legislation has been an almost invariable forerunner of general sickness insurance. In 1910 no state had such legislation. Today all but four have more or less elaborate systems of protection in this field. There is no agitation for their repeal, and little opposition to their continual extension.
>
> That extension has already made "occupational disease" compensable in several states and more are added annually.[2] The tendency is clearly described in a recent report of the Industrial Commission of South Dakota: "The original idea of the workmen's compensation law was that of helping the injured worker to bridge over his troubles until he was again able to resume his ordinary labor. But by actions of legislatures, courts and commisions it is beginning to approach that of a general plan of health and accident insurance." [3]
>
> About 17,000,000 workers are paid more than $150,000,000 annually under these laws at present, an amount *fully* comparable to that expended by many European countries on complete systems of compulsory health insurance. Dentists have been brought under this law in many places and in various capacities.
>
> *This legislation gains greatly in significance* when it is considered as the foundation and framework of future and vastly more extensive systems of insurance, for it now contains nearly all the features of the more extensive European systems to which physicians and dentists most strenuously object. There is little "free choice of practitioner," professional confidence is not respected, there is a mass of lay interference, the tendency to reduce fees to a minimum is already apparent, and charges of undue influence on professional testimony by employers or insurance companies on one side and by malingering employees upon the other are already common.

TYPES OF CONTRACT PRACTICE

The types of contract practice vary according to the organization providing the medical service and the form of contract used. There exist definite conditions under which contract practice is both legitimate and ethical, but these instances cannot be used in defense of unethical, highly competitive and economically unsound methods used by unscrupulous individuals or groups to further commercial or professional avarice.

The type of contract and the services rendered will therefore depend much on the integrity of those who devise and operate the system and are influenced by both the exigencies that call the system into operation and the motives that underlie its operation.

Contract coverage may be one of three types: (*a*) for employment connected injuries; (*b*) for employment connected illness and injuries; (*c*) for injuries and illness which are either employment connected or which may have no relation to employment.

The types of organizations or groups engaged in contract practice are as follows. It is not possible at this time to enumerate all the companies, associations, groups and individuals that would fall in each classification.

A. Large corporations:
    1. Railroads.
    2. Mining companies.
    3. Oil companies.
    4. Logging and lumber companies.
    5. Canneries.
    6. Shipbuilding and allied shipping companies.
    7. Other manufacturing companies.
B. Mutual benefit associations.
C. Hospital associations.
D. Medical groups.
E. Individual physicians.
F. County medical societies.
G. Hospitals.
H. Newspapers.
I. Cooperative groups.

[2] Stewart, Ethelbert: Occupational Diseases and Workmen's Compensation, Monthly Labor Review, February, 1930, p. 93.

[3] Bulletin Association of Casualty and Surety Executives, October, 1930, pp. 9-10.

J. Industrial associations:
  1. Mutual benefit associations.
  2. Trade unions.
K. Lodges.

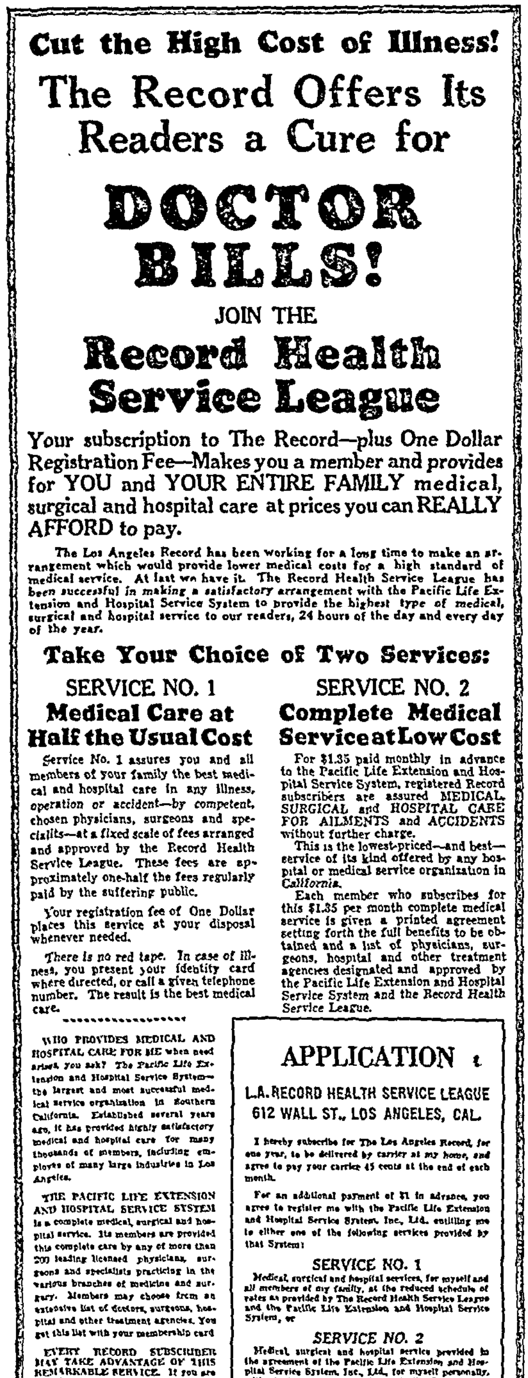
Many large corporations own and operate their own hospitals. Physicians are employed by contract and the employees are cared for on a monthly payroll deduction basis. Some mutual benefit associations also own their own hospital properties and employ physicians in a manner similar to the large corporations, but all this medical service is maintained at the low monthly pay rate for members only. Because of the limited amount of income from members on such low monthly rates, these associations would soon be obliged to discontinue their service were it not for generous endowments left by members and the profit that accrues from hospital care of the public at regular rates.

Hospital associations are misnomers. In most instances they are merely the business offices of groups having medical contracts for sale. These "associations" usually have a few "staff physicians" on salary, but most of the physicians who care for the contract cases are paid on a "piece work" basis. Not infrequently, these physicians have no little difficulty in securing payment for services rendered and then at the amount allowed by some lay business manager whose business it is to deal with the profession as well as with the employers and the employees. It is not uncommon for these czaristic adjusters to dictate to physicians the extent to which their services shall go in an individual case.

Since some of the best medical groups are doing contract practice, naturally the type of service they render is superior to that given by many of the "hospital associations." Even while engaged in contract medicine, these medical groups claim that they are not satisfied with this type of practice; but their disavowal of the practice lacks sincerity, since they continue to use all the methods of the system to hold present contracts and to get new ones.

Much of the anxiety on the part of the profession over contract practice has grown out of the methods used by individual physicians in the field. For instance, one organization of this type is owned and operated by one physician with a large number of associates operating in many communities. A copy of the contract used by this physician will be found in the Appendix marked T-1.

In one particular instance which comes to mind the owner and operator of the contract plan views medical practice with an extremely cold-blooded business attitude. He appears to have no interest in any form of medical charity; he thinks very poorly of organized medicine; his respect for medical ethics is apparently negligible; he realizes that he is under fire but hopes he will be able to retain his county medical society membership. He thorougly believes that his system is the only correct one and that all physicians must ultimately solicit business, but he is sure that organized medicine cannot do this. He refuses to give out the details of his plan, stating that it is worth money to him and if described or published would be used by his competitors to his disadvantage. He is honest in the belief that his is the only "scientific medical insurance," but he is operating his system without any supervision by the state insurance department. He admits that his plan would not be successful in agricultural districts and he prefers not to contract with individuals or with other members of the families of employees, since such contracts require too much bookkeeping and the pay is not assured.



Cut the High Cost of Illness!

The Record Offers Its Readers a Cure for

DOCTOR BILLS!

JOIN THE

Record Health Service League

Your subscription to The Record—plus One Dollar Registration Fee—Makes you a member and provides for YOU and YOUR ENTIRE FAMILY medical, surgical and hospital care at prices you can REALLY AFFORD to pay.

The Los Angeles Record has been working for a long time to make an arrangement which would provide lower medical costs for a high standard of medical service. At last we have it. The Record Health Service League has *been successful in making a satisfactory arrangement* with the Pacific Life Extension and Hospital Service System to provide the highest *type of medical*, surgical and hospital service to our readers, 24 hours of the day and every day of the year.

Take Your Choice of Two Services:

SERVICE NO. 1

Medical Care at Half the Usual Cost

Service No. 1 assures you and all members of your family the best medical and hospital care in any illness, *operation or accident*—by competent, chosen physicians, surgeons and specialits—at a fixed scale of fees arranged and approved by the Record Health Service League. These fees are approximately one-half the fees regularly paid by the suffering public.

Your registration fee of One Dollar places this service at your disposal whenever needed.

There is no red tape. In case of illness, you present your identity card where directed, or call a given telephone number. The result is the best medical care.

SERVICE NO. 2

Complete Medical Service at Low Cost

For $1.35 paid monthly in advance to the Pacific Life Extension and Hospital Service System, registered Record subscribers are assured MEDICAL, SURGICAL and HOSPITAL CARE FOR AILMENTS and ACCIDENTS without further charge.

This is the lowest-priced—and best—service of its kind offered by any hospital or medical service organization in *California*.

Each member who subscribes for this $1.35 per month complete medical service is given a printed agreement setting forth the full benefits to be obtained and a list of physicians, surgeons, hospital and other treatment agencies designated and approved by the Pacific Life Extension and Hospital Service System and the Record Health Service League.

WHO PROVIDES MEDICAL AND HOSPITAL CARE FOR ME when need arises, you ask? *The Pacific Life Extension and Hospital Service System*—the largest and most successful medical service organization in Southern California. Established several years ago, it has provided highly satisfactory medical and hospital care for many thousands of members, including employes of many large industries in Los Angeles.

THE PACIFIC LIFE EXTENSION AND HOSPITAL SERVICE SYSTEM is a complete medical, surgical and hospital service. Its members are provided this complete care by any of more than 200 leading licensed physicians, surgeons and specialists practicing in the various branches of medicine and surgery. Members may choose from an extensive list of doctors, surgeons, hospital and other treatment agencies. You get this list with your membership card

EVERY RECORD SUBSCRIBER MAY TAKE ADVANTAGE OF THIS REMARKABLE SERVICE. If you are already a subscriber, your agreement to continue having The Record delivered at your home or office for one year makes you eligible for either service offered through The Record Health Service League. If you are NOT a subscriber, you become eligible for League membership and service by agreeing to take The Record by carrier for one year.

NO MATTER WHERE YOU LIVE IN SOUTHERN CALIFORNIA, YOU MAY AVAIL YOURSELF OF THIS UNUSUAL SERVICE. Write or call up The Record, TUcker 2121, at any time, and a representative of The Record Health Service League will be glad to explain any detail of the medical and hospital service provided for members.

Reach for Your Scissors Now and Cut the High Cost of Illness by Clipping This Application.

APPLICATION

L.A. RECORD HEALTH SERVICE LEAGUE
612 WALL ST., LOS ANGELES, CAL.

I hereby subscribe for The Los Angeles Record, for one year, to be delivered by carrier at my home, and agree to pay your carrier 45 cents at the end of each month.

For an additional payment of $1 in advance, you agree to register me with the Pacific Life Extension and Hospital Service System, Inc., Ltd., entitling me to either one of the following services provided by that System:

SERVICE NO. 1

Medical, surgical and hospital services, for myself and all members of my family, at the reduced schedule of rates as provided by The Record Health Service League and the Pacific Life Extension and Hospital Service System, or

SERVICE NO. 2

Medical, surgical and hospital service provided in the agreement of the Pacific Life Extension and Hospital Service System, Inc., Ltd., for myself personally, without charge, as long as I pay to the System $1.35 per month, the reduced rate arranged for me by The Los Angeles Record.

It is understood and agreed that my membership in The Record Health Service League, and eligibility for service at the rates quoted under either of the above plans, shall continue only as long as I am a subscriber to The Record.

I select Service No.........

I enclose $1 for registration.

Display advertisement occupying three full columns of a western newspaper early in November, 1931.

From reliable sources it is reported that this physician has stated that his contract practice is only 40 per cent of his entire business. In this instance, as in most contract practices, the exemptions (not covered by contract) and the patients not covered by contract but brought in by contract covered individuals help to increase the gross income. This physician is very inflexible in his attitude toward the organized profession and he is determined to influence employers to demand of the state legislature that the present contract system be retained and protected. This attitude is held by many contract physicians.

In an effort to meet the growing competition of contract individuals and medical groups, one or more county medical societies have devised plans to take contracts as organized bodies. These societies were motivated by the desire to furnish to the low income group a medical service at a small cost, to render the same quality of service as that given their regular fee patients, to offer free choice of physician, and to eliminate unfair competition among the physicians in the community. In attempting to solve the problem, the county society has been drawn into using some of the same methods of contract getting used by other contract groups; viz., the business manager or solicitor. A copy of the type of contract used by one county medical society group will be found in the Appendix marked T-2. It was found impossible to enlist the support of the entire county medical society membership in this project, only about 50 per cent agreeing to the plan.

Hospitals have entered the field of contract practice by assuming the business management of contract solicitation. This form of contract practice is no less devoid of the unethical and undesirable features than the types already mentioned.

A recent venture in contract practice is a plan announced by a western newspaper, a display advertisement of which appeared in an early November, 1931, issue of the paper in question. The advertisement, a reduced reproduction of which appears in the accompanying illustration, says:

> Cut the High Cost of Illness!
>
> The [paper] offers its readers a cure for Doctor Bills!
>
> Join the ——— Health Service League. Your subscription to the [paper] plus one dollar Registration Fee—Makes you a member and provides for you and your entire family medical, surgical and hospital care at prices you can really afford to pay.
>
> The [paper] has been working for a long time to make an arrangement which would provide lower medical costs for a high standard of medical service. At last we have it. The ——— Health Service League has been successful in making a satisfactory arrangement with the ——— System to provide the highest type of medical, surgical and hospital service to our readers, 24 hours of the day and every day of the year.
>
> Take your choice of two services:
>
> Service No. 1, medical care at half the usual cost: Service No. 1 assures you and all members of your family the best medical and hospital care in any illness, operation or accident—by competent, chosen physicians, surgeons and specialtists—at a fixed scale of fees arranged and approved by the ——— Health Service League. These fees are approximately one-half the fees regularly paid by the suffering public.
>
> Your registration fee of One Dollar places this service at your disposal whenever needed.
>
> There is no red tape. In case of illness, you present your identity card where directed, or call a given telephone number. The result is the best medical care.
>
> Service No. 2, complete medical service at low cost: For $1.35 paid monthly in advance to the ——— System, registered ——— subscribers are assured medical, surgical and hospital care for ailments and accidents without further charge.
>
> This is the lowest-priced—and best—service of its kind offered by any hospital or medical service organization in the state of ———.
>
> Each member who subscribes for this $1.35 per month complete medical service is given a printed agreement setting forth the full benefits to be obtained and a list of physicians, surgeons, hospital and other treatment agencies designated and approved by the ——— System and the ——— Health Service League.
>
> Who provides medical and hospital care for me when need arises, you ask? The ——— System—the largest and most successful medical service organization in [state]. Established several years ago, it has provided highly satisfactory medical and hospital care for many thousands of members, including employees of many large industries, in [city].
>
> The ——— System is a complete medical, surgical and hospital service. Its members are provided this complete care by any of more than 200 leading licensed physicians, surgeons and specialists practicing in the various branches of medicine and surgery. Members may choose from an extensive list of doctors, surgeons, hospital and other treatment agencies. You get this list with your membership card.
>
> Every ——— Subscriber may take advantage of this remarkable service. If you are already a subscriber, your agreement to continue having the [paper] delivered at your home or office for one year makes you eligible for either service offered through the ——— Health Service League. If you are not a subscriber, you become eligible for League membership and service by agreeing to take the [paper] by carrier for one year.
>
> No matter where you live in [state], you may avail yourselves of this unusual service. Write or call up the [paper], [telephone number] and a representative of the ——— Health Service League will be glad to explain any detail of the medical and hospital service provided for members.
>
> APPLICATION
>
> ——— Health Service League at [address]
>
> I hereby subscribe for the [paper] for one year, to be delivered by carrier at my home, and agree to pay your carrier 45 cents at the end of each month.
>
> For an additional payment of $1 in advance, you agree to register me with the ——— System, Inc. Ltd., entitling me to either one of the following services provided by that system:
>
> SERVICE NO. 1
>
> Medical, surgical and hospital services, for myself and all members of my family, at the reduced schedule of rates as provided by the ——— Health Service League and the ——— System; or
>
> SERVICE NO. 2
>
> Medical, surgical and hospital service provided in the agreement of the ——— System, Inc., Ltd., for myself personally, without charge, as long as I pay to the System $1.35 per month, the reduced rate arranged for me by the [paper].
>
> It is understood and agreed that my membership in the ——— Health Service League, and eligibility for service at the rates quoted under either of the above plans, shall continue only as long as I am a subscriber to the [paper].
>
> I select Service No ....
> I enclose $1 for registration.
> I $\left(\begin{smallmatrix}\text{am}\\ \text{am not}\end{smallmatrix}\right)$ a subscriber to the [paper].
> Name ....
> Address ....
> City .... Phone ....
>
> To the Subscriber:
>
> If you do not receive your membership card within five days of making application, please notify the ——— Circulation Manager, [telephone at] [address].
>
> Reach for your scissors now and cut the high cost of illness by clipping this application.

From such a glaring account it would appear that health and medical relief is indeed at the crossroads of the bargain counter. But to those who know it is perfectly clear that the rates quoted are utterly inadequate to provide any medical services except the barest first aid for minor afflictions. The proposition is thoroughly unsound economically since to provide complete medical services at such prices would mean swift bankruptcy for any honest and conscientious individual or group.

The most recent venture in contract practice is announced from another section of the country where certain groups of cooperatives in a certain industry are being led into a scheme for cut rate medical care by a physician not in active practice who defies all medical organizations to interfere with his experiment. This plan is so new that no details of its working can be obtained; suffice it to say that the physician promoter flatly refuses to take into his confidence for council, assistance or guidance the local medical societies in the territory over which the scheme is to operate.

MUTUAL BENEFIT ASSOCIATIONS AND TRADE UNIONS

Industrial mutual benefit associations and trade unions have not strongly entered the field of contract practice. These organizations have, for the most part, confined their interests in and efforts toward the protection of the income of their members. In some instances, however, sick benefit funds have been established but participation in these funds is usually limited to those cases not entitled to payments under the workmen's compensation laws.

A study of mutual benefit associations recently made by Brundage and reported in *Public Health Reports* shows that an appreciable number of these associations provide some medical service and care to their members.

LODGE PRACTICE

Lodge practice, as usually found, consists in the employment of a physician by a local fraternal organization to serve its members on contract, by salary or for a stipulated sum per member annually. Medical and surgical services and hospital care are provided for members on the basis of a monthly membership fee. In most instances, medical and hospital benefits provided by the lodge for its members are contingent on the member using the physicians or hospitals approved and designated by the lodge. It is not known what considerations govern in the selection of physicians and hospital facilities.

Lodge practice assumes its largest proportions in the care of tuberculous and the aged or retired members. Several large institutions for these purposes have been established for many years. Tuberculosis sanatoriums are also maintained by some of the trade unions.

METHODS OF OPERATION AND QUALITY OF SERVICE

Throughout the contract proponent groups there exists a definite fear or obsession lest the organized medical societies object or interfere with contract operations. Likewise, there is a craftiness in business dealings and a circumvention of accepted ethics in many contract plans.

As long as contract practice remained in the field of practical necessity, it created little or no alarm. But, as the exigencies of pioneer projects passed, the emergency methods of medical care were not discarded but were retained to become the basis of new schemes to compete with regularly established medical practice. Workmen's compensation laws were passed and funds became available with which to pay for the medical care of the injured employee. These funds, which assured the payment of fees for hundreds of thousands of potential patients, became the envy of the conniving contract cliques. At this point a method was introduced in contract practice similar to pressure selling in the business world.

In the medical profession, in which no ethical individual advertises, he who first adopts the practice, although by so doing he becomes unethical and is marked a quack, wins interest at once with very little expenditure. Certain types of contract schemes would not be successful if contract physicians were obliged to wait until business and industry sought them out for their particular services. Therefore, an advertising method was adopted to carry the message, at first, to organizations having a large number of employees, later to small industries, laundries, garages, business houses, apartment houses and even individuals. The business agent, manager, capper, adjuster or solicitor thus became the advertising agent of the contract physician or group. With the incorporation of this element into contract practice methods, pressure of getting business became greater, new groups or associations were formed to enter the contract field, and definite unfair competition with private medical practice was created. It was then a short and easy step to underbidding and misrepresentation to get contracts.

Although it is claimed that the quality of service is as good as can be had anywhere, there is sufficient evidence to show that this is not universally true. Under some contracts, patients are treated by remote control, at long distances. Patients often prefer to pay the family physician to manage a serious illness or to do an operation rather than to accept the services of the contract physician or staff. It is charged that some contract physicians do as little as possible for their contract patients since to treat them well would encourage them to demand more treatments, calls or medicine than are considered necessary by these contract physicians.

It is appropriate here to quote the following statements taken from a report on contract practice prepared by a special committee of the ——— County Medical Society appointed to study the question of contracts operating under the state law and to define the position of the medical profession with respect to this subject:

> Early in 1930 the ——— County Medical Society ordered a fact finding investigation and the initiation of efforts to correct certain conditions which were known to have progressed to the point of having become public health problems.
>
> Official action of the medical society limited the activities of the committee to three specific problems:
>
> 1. Certain contracts under the ——— law.
> 2. Certain so-called medical contracts executed by doctors contracting under the ——— law.
> 3. Commercial solicitation of professional business, particularly to secure the above contracts, either by physicians themselves or by lay agents hired direct or through corporate agencies.
>
> The ——— law has been in operation thirteen years. Conceived in altruism toward the workmen to ease the financial burden incident to the surgical care of injuries, it has made possible the exploitation of the medical aid fund by contract doctors for profit to the possible tragic detriment of the injured, a condition contrary to good financial policy and good public health policy.
>
> The law legalizes contracts and provides that the employer and employees in conference may choose the contract alternative. It does not provide nor does it specifically prohibit, nor was it the intent of the law that doctors should take the initiative, go themselves or send their hired lay representative to employers and groups of employees to solicit the contracts as they have done and are now doing.
>
> Under the terms of the contracts as executed by contract doctors, ten cents on the dollar of the medical aid trust fund goes to the state for administrative expense; ninety cents on the dollar, at the time of collection from labor and industry, is turned over to the contract doctor. He is custodian of the fund; he administers it, determining what services shall be rendered, including his own professional services, hospital, nurses, drugs, appliances, and even professional consultants. He disburses for all services and keeps as his own the unexpended portion.
>
> Therein lies the censurable financial policy, and therefrom arise the possibilities of detriment to public health.
>
> In exploiting financial possibilities for personal gain under the law, contract doctors sometimes reduce services to injured workmen to the point of inadequacy and inefficiency. Under their administration of the fund a leg may be amputated to save the hospital expense incident to effort to save the leg, or workmen with fractures and serious internal injuries may be allowed to succumb without effort to determine and treat the internal injuries because of the hospital expense entailed during repair of the fractures in case life is saved. They hire laymen to solicit the contracts, thereby diverting a considerable portion of the fund to channels of commercialism, and as a corollary to the ——— law contracts, contract doctors are carrying on a wildcat health insurance business. They are known to have paid up to 20 per cent of the gross revenue derived from the contract and up to $600 a month to lay agents through whom the contracts were secured. Through the use

of hired lay agents they secure contracts remote from their home town, then sublet to local doctors for 25 per cent of the total revenue, their sole service being to secure and to sublet the contract, or they hire the cheapest available local doctor to render service under the remote contracts and often require him to pay them 50 per cent of the gross revenue derived from all private practice developed while in their employ.

In some instances a local physician has secured the necessary signature to the petition intending to take over the contract for the industry. Remote organizations hearing of the fact, through influence they could bring to bear, caused word to be sent to the mill that the employees should rescind their signatures immediately or if necessary every employee would be fired and an entire new crew hired. In these instances the workmen contributed 50 per cent of the revenue and under the law are supposed to have equal authority with the employer regarding who shall do their medical work under the law. A remote group of physicians is so intrenched that they are able to take the bread and butter from the mouths of laborers, their wives and children unless the medical aid contract is awarded to them. The workmen have grievances on this score and about the adequacy and efficiency of the services to the injured, but they dare not protest.

The groups of workmen included under the ——— law comprise convenient groups to bring into the wildcat health insurance activities. For from seventy-five cents to one dollar and fifty cents a month, contract doctors agree to render all professional services and pay all costs incident to the care of accidents not included under the ——— law and all sicknesses with specific limited exceptions. This contract is a limited health and accident insurance policy with all the evil possibilities of wildcat insurance, to wit:

1. The contract doctor is the insurer.
2. The insurer is unsupervised as to financial resources, and as to performance under his contract.
3. He determines the rates, administers the insurance fund, determines what services shall be rendered, renders that service personally or through agents in his hire, and retains the unexpended portion.

Any insurance actuary will testify to the fact that the rate is utterly inadequate; every man operating would go bankrupt in a short time if he fulfilled the terms of the contract. Any unprejudiced physician will testify to instances of failure of the insurer to fulfil his contract.

A man with a perforating ulcer of the duodenum went nine times to the contract doctor. The eighth and ninth times he was so ill his son had to take him after refusal of the contract doctor to call at the home. No adequate history was obtained, absolutely no examination was made. He was given a box of pills, some ten cents in value, which proved so laxative that their use had to be discontinued. He then consulted his family physician, who rendered proper service, including hospitalization and operation, incurring some $400 expense. The contract doctor wilfully and negligently evaded financial obligation, the professional responsibility and effort to save for himself the cost of hospitalization and special nurses.

The ideals and ethics of the medical profession have through all time paralleled very closely the ideals and ethics of the legal profession. The ——— act of the state of ——— specifically prohibits the use of hired lay solicitors for securing professional work for lawyers. It is declared to be against public policy. The ——— act of the state of ——— does not contain any similar clause, although seventeen states and territories do have laws prohibiting the practice with revocation of license as the penalty.

CLOUDING OF CONTRACT CLAUSES

Not all patients having contract privileges understand the coverage or exemptions of the contract. Under the pressure of increasing competition, the agent or solicitor may have misrepresented the coverage when making the sales. The patient suffers from these fraudulent methods when he finds that conditions for which he presents himself for treatment are not included in the contract and therefore he must pay for the treatment or seek a private physician. Almost all types of contracts, except those used by the cooperative groups and newspapers, cover the industrial workers only. It is claimed that there is too much bookkeeping to warrant taking contracts with individuals not on a payroll or members of the employee's family. Whatever the advantages claimed for strictly industrial contract practice, these benefits cannot accrue to women, unless they are employees, and in no case to children.

PREVENTIVE MEDICINE DISREGARDED

In only one instance that has come to our notice is any attention ever given, under contract coverage, to preventive medicine. Generally speaking, contract practice is essentially curative medicine and the person who wishes to keep well by such means as the periodic health examination must still use his family physician or pay the contract group. Even though preventive medicine were to be practiced in contract medicine, two groups with which prevention is most important and effective, viz., women and children, would not be touched except for the few women who might be employed in the contract covered groups.

FREE CHOICE OF PHYSICIAN A MISREPRESENTATION

It is claimed that some contract plans offer the individual covered a free choice of physician. It is possible that there are such plans contemplated but, as far as is known at present, there is no plan which includes all the physicians in a community. It is usually stipulated that such free choice of physician is limited to those physicians who are associates of or who are approved and designated by the contract holders. Use of the term "free choice of physician" is, under these conditions, definitely misleading if not fraudulent misrepresentation.

EFFECT OF CONTRACT PRACTICE ON THE PUBLIC

Contract practice has created in the minds of both the individual and the public a false impression of physicians and medical service. In contract practice not only the financial or business but also the intimate professional relationships between patient and physician are changed. These relations, which for centuries have been peculiarly close and personal, are now robbed of that intimacy and friendliness of understanding which characterizes medical practice.

Now contract advocates come out with a new, high powered model of medical service characterized by mass production methods, short cuts and abbreviations in procedure which benefit the physician or group not the patient, cold impersonality, long distance remote control and cash-in-advance payments.

There is little occasion for surprise that the layman who comes in contact with such a pseudoprofessional process and who analyzes it should consider the physician in the scheme a mere robot and his treatment procedures only stereotyped mechanical mimicry.

Most types of contract practice are devised for the promoters and not for the patients. It is because of this fundamental fallacy that confidence in the profession is disturbed. Nor is the quality of medical service the only element that influences profoundly the establishment and maintenance of confidence. The rates charged for contract work imply that all other medical fees are unreasonably high. When the truth is known, contract practice is not a complete coverage. Were it not for the exemptions, the dodging of responsibility and the almost 100 per cent collection guarantee, the holders of contracts would be forced to discontinue the practice because of its economic impracticability.

Contract rates also imply that physicians have a sliding range of fees. Medical and surgical treatment are indefinite scientific services measured in nature and amount according to the demands of the individual. Medical service, therefore, is not comparable to commodities sold by units of measure or weight, which are always constant. The bidding and underbidding and bargaining and adjusting practiced in securing contracts places medical services on a level with ordinary merchandise.

CONTRACT PRACTICE DEFINED

This brief discussion, with the few examples cited, is intended to stimulate an earnest, exhaustive examination of the methods of providing medical service rather than to describe completely the complex and disturbing system known as contract practice.

The Judicial Council has defined "contract practice" in the following words:

> By the term "contract practice," as applied to medicine, is meant the carrying out of an agreement between a physician or group of physicians as principals or agents and a corporation, organization or individual, to furnish partial or full medical services to a group or class of individuals for a definite sum or for a fixed rate per capita.

This definition, I believe, will be found to cover every form of contract practice. It will be observed that in the definition no mention is made of the ethics of the practice for the reason that contract practice per se is not an ethical question, ethics being concerned with the form of the contract and the conditions under which it is made. That there are many conditions under which contract practice is not only legitimate and ethical, but in fact the only way in which competent medical service can be provided, becomes evident on analysis. For instance, when large numbers of workmen are employed remote from urban centers, as in some mining or logging camps, efficient medical service can be secured only by contracting with some competent physician to do the work. Certain industrial situations arise wherein large employers of labor are compelled by law to provide medical services for their employees under certain conditions, and this at times can be secured only by some form of contract. A community too small to offer sufficient inducements to a competent physician to locate therein may secure one by some form of contract or agreement as to compensation. It is perfectly evident, therefore, if one is to judge whether a contract is ethical or not, that the form and terms of the contract must be known, as well as the particular circumstances under which it is made. As there is such a great variety of contracts, and as their form and the circumstances under which they are made differ so widely, it seems impossible, or at least inadvisable, to attempt to define what constitutes an ethical contract. Each case must be judged on its own merits after all the facts pertaining thereto are known. There are certain points, however, that may be formulated which, when present, one or more of them, definitely determine a contract to be unfair or unethical. These may be stated as follows:

1. When the compensation received is inadequate, based on the usual fees paid for the same kind of service and class of people in the same community.
2. When the compensation is so low as to make it impossible for competent service to be rendered.
3. When there is underbidding by physicians in order to secure the contract.
4. When a reasonable degree of free choice of physicians is denied those cared for in a community in which other competent physicians are readily available.
5. When there is solicitation of patients directly or indirectly.

In the interpretation of the rules of ethics as applied to the practice of medicine: (1) By the word "practice" is meant the performance or application of medical knowledge; (2) by "solicitation" is meant to bespeak professional patronage by oral, written or printed communications either directly or by an agent; (3) by "patient" is meant any person ill or otherwise.

SO-CALLED HOSPITAL AND HEALTH ASSOCIATIONS

In its report to the House of Delegates at Philadelphia, the Judicial Council gave consideration to the ethical and economic status of so-called hospital and health associations, controlled by groups of laymen, or by individuals, offering medical and hospital service to any who will buy "membership" and pay a nominal sum each month as "dues."

The Judicial Council's report states: "Such schemes have been put into operation in various places and have failed within a few weeks or months because of inadequate income or because of failure to render good service. The Judicial Council has regarded these schemes as being economically unsound, unethical and inimical to the public interest.

"Within the last year, (1930-31) some community hospitals have announced their intention to provide medical, surgical and hospital service to families on a flat rate basis. In at least one instance, such service has been offered to families for $35.00 a year, irrespective of the number of members in such families. In most instances, certain exceptions are made in that persons with chronic diseases are not entitled to receive the benefits of the plan and obstetrical service is not supplied without additional compensation. The members of the Judicial Council doubt that it is wise to lead the people in any community to believe that all necessary medical and hospital service, even though chronic diseases and obstetrical care be excepted, can be provided for the average family for $35.00 a year. In the cases presented to it the Judicial Council has advised against adoption of such plans by community hospitals because it is believed that they are not economically sound in that they may be unfavorably affected by conditions entirely beyond control under which contracts cannot be fulfilled. There are other aspects of the matter that readily present themselves for consideration involving the interests of physicians in the community who cannot participate in such plans."

With these definitions and explanations it should not be difficult to determine the ethics of any type of contract practice. Personal interests and professional advantages must be eliminated when judging the merits of each plan; the welfare of patients, the integrity and competence of those operating the plan, and the method and adequacy of meeting the medical fee should receive first consideration.

TIME FOR THOROUGH INVESTIGATION AND MODIFICATION

The organized profession has no desire to obstruct reasonable and honest efforts to provide the best medical care possible to persons receiving low incomes. In examining the methods now being promoted to accomplish this end, it is essential that the welfare of the individual be kept always foremost.

It is believed that the success of any system must be predicated on the separation of the medical service rendered by the profession and the collection and administration of funds with which to pay for the service. Furthermore, it is believed that the practice of requiring physicians to certify to cash benefits must be modified or entirely eliminated. The physician's chief interest and duty should be in the care appropriate to returning his patient to normal health as soon as possible; his is a service benefit to the patient and he should not be made the "goat" in passing judgment by certificates or otherwise on cash benefits in which his patient may share.

Since contract practice is essentially a form of insurance benefit, it becomes necessary to consider well the method of certifying incapacity for work in any modification of the present system.

It is well, also, to consider whether we are undertaking, in the preparation of physicians, to produce a brand of professional attainment which we shall not be able to use because of the cost. Is the medical profession entering an era of transition or must it develop a changed method of practice to meet changing social trends?

Is the culmination of centuries of development, research and refinement in medicine to become a mere mechanical manipulation controlled by a few nonmedical managers or shall the medical profession perfect its own methods of providing sound, scientific service at prices people can pay?

SUMMARY

Although there are many details of contract practice which deserve much more detailed description and comment than is possible in this report, it may be stated that contract practice

1. Took its origin largely from necessity;
2. Has been legalized, in certain places by state statute;
3. Under certain conditions and in some forms is both ethical and legitimate;
4. In general, has become highly commercialized and competitive;
5. Is largely limited to the pay roll class;
6. Does not, in most cases, extend its provisions to women and children;
7. Concerns itself, almost without exception, to curative medicine and does not include preventive measures;
8. Shows no interest in public or individual welfare;
9. Furnishes medical care which is often inferior in character;
10. In many instances is characterized by underbidding, subletting, misrepresentation and racketeering;
11. Is economically unsound in many of its present forms;
12. Is essentially sickness insurance usually not supervised or regulated;
13. Is often used by the operators thereof to influence legislation in favor of extension of the plan;
14. In many of its present forms, lowers the confidences of both the individual and the public in the medical profession;
15. Has some features that deserve refinement and extension and others that are unethical and dangerous and should be abolished.

535 North Dearborn Street.

APPENDIXES

The following appendixes are examples of some of the contracts to which reference has been made in the foregoing article. The form and wording of the contracts are based on information that has been received by the American Medical Association and documents on file in its headquarters.

APPENDIX T-1

THIS AGREEMENT, entered into between THE ——— CLINIC of ———, party of the first part, and ———, of ———, party of the second part,

WITNESSETH: The party of the first part in consideration of the payment by the party of the second part of the sum of money herein mentioned hereby agrees to furnish, perform, and render to the employes of the party of the second part the following medical service:

HOSPITAL SERVICES: Care in a ward bed of the ——— or ——— General or ——— Contagious Hospital as long as necessary, but not to exceed six months, for such conditions as are ordinarily accepted by the management of aforesaid hospital. Private room and private nurse in necessary cases will be furnished at the discretion of the party of the first part.

Operating room, laboratory work, plaster cast, x-rays and all drugs and medicines, will be furnished while at the hospital.

SURGICAL SERVICES: All surgical services for operations or injuries not provided for under the State Compensation Act will be furnished.

SICKNESS: All diseases, including contagious diseases, such as smallpox, diphtheria, scarlet fever, etc., will be taken care of at the above mentioned hospitals, or at home, or our office.

ADDITIONAL SERVICE: All medicines, drugs, prescriptions at authorized drug stores, crutches, braces, surgical belts, dressings, plaster casts, and splints will be furnished. All necessary laboratory work, x-rays, including dental x-ray, and all examinations for glasses (but not including glasses), will be furnished. Insulin will be furnished for a period of six months.

House calls when necessary will be made.

Ambulance service in necessary cases will be furnished.

A physical examination, including dental examination and x-ray of teeth when necessary, will be given free of charge to the employees and prospective employees when desired by the employer.

First aid training will be given to the safety men of the firm at stated intervals. Necessary first aid kits and supplies will be furnished.

EXCEPTIONS: Venereal diseases, conditions peculiar to sex, and conditions existing before commencing to pay medical fees under this contract.

GENERAL AGREEMENTS: Party of the first part agrees to at all times maintain a staff of at least a Major Surgeon, Physician, Eye, Ear, Nose and Throat Specialist and a Dentist.

Complete x-ray, physiotherapy, and laboratory departments and 24-hour telephone service will be maintained.

The party of the second part agrees to notify the party of the first part of any sickness or injury requiring medical or surgical services. In no event will the party of the first part pay for services of any physician or surgeon other than those designated by said party of the first part, nor be liable for or pay for any services, bills or expenses, unless authorized and approved by the party of the first part.

When deemed necessary by the party of the first part, services of a specialist to be designated by said first party will be furnished.

PAYMENTS: That the said party of the second part shall collect from each of its employes the sum of ten cents per day for the first ——— days of each month or any fraction thereof that each man in their employ works, and that the moneys so collected is a trust fund as provided by Chapter 136 of the Session Laws of 1929, and that the second party shall hold same in trust and pay same to the party of the first part on or before the 20th day of the month following collection.

This contract shall become effective ——— and continue for a period of ——— years.

THE ——— CLINIC,
Party of the First Part,
By ——— .
———, Party of the Second Part,
By ———.

APPENDIX T-2

THIS AGREEMENT, made this first day of ———, 193, between the ——— COUNTY INDUSTRIAL MEDICAL AND SURGICAL SERVICE BUREAU, INC., of ———, party of the First Part, and ———, Party of the Second Part:

WITNESSETH:

HOSPITAL SERVICE:

That in consideration of the prompt payment by said Party of the Second Part of the amount hereinafter set forth, said Party of the First Part agrees to furnish medical and surgical treatment to those employes of said Party of the Second Part who may require same. Such services and care to be prompt and efficient, without discrimination or favoritism, and to cover injuries occurring at all times not covered by the First Aid Law, and illness, with exceptions as hereinafter noted.

Said treatment to consist of medical and surgical attendance, including operations, drugs, medicines, nursing, bed and board in a ward of the

——— General Hospital, or ——— Hospital (at the option of the patient), in the City of ———. The use of an ambulance will be allowed when necessary. Said service and treatment not to exceed ninety days (accidental injuries and surgical operations excepted).

NON-HOSPITAL SERVICE:

In the event of any employee or said Party of the Second Part needing the services of a physician, but not needing hospital care, said Party of the First Part agrees to furnish treatment at the office of the physician chosen or at the home of the employee if necessary. Said treatment to include all necessary drugs, medicines, dressings, etc. Prescriptions will be filled free of charge at drug stores designated. Said treatment and service not to exceed ninety days (accidental injuries and surgical operations excepted).

Eye injuries and diseases of the eye shall receive the immediate attention of an eye specialist.

PAYMENTS:

The employees of said Party of the Second Part shall be divided into two groups as regards payment.

The first group shall include all those employees who come under the State Medical Aid Law, and who are covered by the First Aid contract which is a joint contract herewith. The Party of the Second Part agrees to pay to the Party of the First Part for each employee of the group, the sum of ——— per month, which together with the amount provided in the First Aid Contract, shall constitute full payment.

The second group shall include all those employees who do not come under the provisions of the State Medical Aid Law. The Party of the Second Part agrees to pay the Party of the First Part for each employee of the second group, the sum of ———.

All payments to be made on or before the 15th of each month for the pay-roll of the previous month.

The Party of the First Part reserves the right to inspect the pay-roll of said Party of the Second Part to ascertain the number and identity of employees. The said Party of the First Part shall not be held liable for treatment under this contract while said Party of the Second Part shall be in default of any monthly payment.

EXCEPTIONS:

Illness not common to both sexes; illness or disability caused by or received while insane; injuries incurred while fighting, rioting, or otherwise violating the law; caused by or resulting from the use of narcotics or intoxicants; venereal diseases and tuberculosis are not entitled to care or treatment under this contract.

GENERAL AGREEMENTS:

The employees of said Party of the Second Part shall be entitled to select any physician, surgeon or specialist, who is a member of the Bureau, a list showing said membership to be posted at the place of employment.

The party of the first part shall not be liable for the bill of any physician who is not a member of the Bureau.

Any employee entitled to medical attendance or hospital care, shall present to his physician an order for treatment properly filled out and signed by some one representing said Party of the Second Part with authority to issue same.

Employees entering the hospital must comply with the rules and regulations thereof and the orders of the physician in charge of the case and in case of their failure to do so, they may be excluded therefrom and shall not be entitled to further services hereunder.

Said Party of the First Part shall not be held liable for treatment of any injury or sickness existing prior to the employees entering the employment of said Party of the Second Part, or before commencing to pay medical dues. Said Party of the First Part shall not be held liable for treatment of sickness or injury after the termination of this contract, or after the patient has left the employ of said Party of the Second Part.

Said Party of the First Part shall pay for all x-ray pictures when authorized. Appliances such as glasses, atomizers, rubber stockings, and plates, shall not be paid for by the Party of the First Part.

This contract is a joint contract with the State First Aid Contract of even date herewith between the parties hereto, and shall terminate jointly with said First Aid Contract in case of legislative change, or it may continue from year to year, and may be canceled by either party giving thirty days' written notice to the other party of its intentions so to do.

IN WITNESS WHEREOF, the parties hereto have caused this agreement to be executed in duplicate by their proper officers on the day and year first above written.

By ———, Party of the First Part.
By ———, Party of the Second Part.

APPENDIX L R-1

Copy of Identification used in plan 1
Personal Identification Card
for members of
——— HEALTH SERVICE LEAGUE

This is to certify that the bearer, whose name is signed hereto, is a member of The ——— Health Service League, and as such is entitled to the benefits of the special rates for medical, surgical and hospital services by physicians and surgeons and other treatment agencies provided by The ——— System, for bearer and family.

It is understood that in consideration of the special arrangement, the bearer is to pay cash for services or comply with the credit requirements of the respective systems.

It is further understood that the bearer's membership in The ——— Health Service League, with accompanying benefits, is contingent upon his remaining a subscriber to The ——— for one year from this date.

Date ———.

Member's Signature ———.

APPENDIX L R-2

APPLICATION FOR "DESIGNATED AND APPROVED" PHYSICIAN & SURGEON OF THE ——— SYSTEM, ———, - ———.

Date ———, *193—.*

TO ———
——— System, Inc., ———.

I hereby make application for appointment as one of your "designated and approved" physicians and surgeons.

I declare that I am a graduate, licensed, registered physician and surgeon in the State of ———.

I further declare that I am now or my qualifications are such that I am eligible to become a member of the medical society in the county in which I reside.

I agree to faithfully fulfil my professional obligations to my patients to the best of my ability and to cooperate with the instructions, rules and regulations of your "System."

I understand that I am to charge for my professional services in accordance with your approved fee schedule, which is based upon fees the same as or similar to those as set forth in that which is generally referred to as the ——— Compensation Fee Schedule.

I graduated from ——— Medical School in [year].

Signed ———, M.D.
Office Address ———.
Office Telephone Number ———.
Residence Address ———.
Residence Telephone Number ———.

City ———.

Council on Pharmacy and Chemistry

NEW AND NONOFFICIAL REMEDIES

THE FOLLOWING ADDITIONAL ARTICLES HAVE BEEN ACCEPTED AS CONFORMING TO THE RULES OF THE COUNCIL ON PHARMACY AND CHEMISTRY OF THE AMERICAN MEDICAL ASSOCIATION FOR ADMISSION TO NEW AND NONOFFICIAL REMEDIES. A COPY OF THE RULES ON WHICH THE COUNCIL BASES ITS ACTION WILL BE SENT ON APPLICATION.

W. A. PUCKNER, Secretary.

DIPHTHERIA IMMUNITY TEST (SCHICK TEST) (See New and Nonofficial Remedies, 1931, p. 383).

Eli Lilly & Company, Indianapolis.

Diphtheria Toxin for Schick Test, Diluted Ready for Use-Lilly.—A diphtheria toxin diluted with physiological solution of sodium chloride containing 0.1 per cent gelatin and having a p_H of 7.8 to 8.0. The diluted toxin is of such strength that 0.1 cc. (one dose) given intracutaneously constitutes one-fiftieth minimum lethal dose for a guinea-pig of 250 Gm. weight. It is marketed in packages of one vial containing sufficient for ten tests (V-926), and in one vial containing sufficient for 100 tests (V-928).

NORMAL HORSE SERUM (See New and Nonofficial Remedies, 1931, p. 346).

Lederle Laboratories, Inc., Pearl River, N. Y.

Normal Horse Serum (1:10 Dilution) for the Conjunctival Test.—Normal horse serum one part, diluted with physiological solution of sodium chloride nine parts, and containing 0.4 per cent chlorbutanol. Marketed in packages of one vial with dropper outfit. To determine hypersensitiveness to the proteins of horse serum, one drop is placed in the conjunctival sac.

SCARLET FEVER STREPTOCOCCUS ANTITOXIN (See New and Nonofficial Remedies, 1931, p. 353).

The Gilliland Laboratories, Inc., Marietta, Pa.

Scarlet Fever Streptococcus Antitoxin (Refined and Concentrated).—It is prepared by the method of Drs. Dick under U. S. patent 1,547,369 (July 28, 1925; expires 1942) by license of the Scarlet Fever Committee, Inc. The serum is concentrated by the method employed in concentrating diphtheria antitoxin. Marketed in packages of one syringe containing 2,000 units (prophylactic dose), and in packages of one syringe containing 10,000 units (therapeutic dose).

TRICHLOROETHYLENE. — Trichloroethylenum. — Trichlorethylene.—$CHCl:CHCl_2$.—1-chloro-2-dichloro-ethylene.

Actions and Uses.—The actions of trichloroethylene have not been investigated comprehensively, and it was introduced into therapeutics following some observations on man. Trichloroethylene appears to have a selective action on the sensory endings of the trigeminal nerve, whereby it affords relief in trigeminal neuralgia, but it is not clear that the action even of therapeutic doses is limited to these endings, and different individuals seem to show rather wide differences in susceptibility to this action; hence the dose necessary to afford relief varies correspondingly. Therapeutic doses sometimes cause transitory giddiness, with lassitude, distress, palpitation and nausea. Large doses cause narcosis, and excessive doses cause death. There was no perceptible injury to the lungs, heart or liver after narcosis repeated several times in the dog, but there was slight hyperemia of the gastric mucous membrane and marked reddening of the duodenum. The liquid is irritant; hence it should not be allowed to come in contact with the nose when the vapor is inhaled.

Dosage.—Fifteen minims by inhalation, to be repeated after a few minutes if necessary; but it appears probable that not more than 60 minims should be inhaled within twenty-four hours when it is used for any considerable period of time.

Trichloroethylene occurs as a clear, colorless, mobile and volatile liquid, possessing an odor similar to that of chloroform. It is miscible with ether and very soluble in alcohol; it is practically insoluble in water. The specific gravity is from 1.458 to 1.460 at 25 C. The refractive index is from 1.4770 to 1.4780 at 20 C.

Transfer 25 cc. of trichloroethylene to a distilling flask. Determine the distillation range according to Method I of U. S. Pharmacopeia X. Ninety-five per cent distils over at from 86 to 88 C. (corrected) at 760 mm. The refractive index of the distillate is the same as that of the material before distillation.

Transfer 5 cc. of trichloroethylene to a glass stoppered cylinder, add 5 cc. bromine water and shake the mixture vigorously at intervals of fifteen minutes: at the end of an hour a white turbid solution forms in the lower layer. Agitate gently 5 cc. of trichloroethylene with 2 cc. of silver ammonium nitrate solution in a narrow glass stoppered cylinder of from 10 to 15 cc. capacity: no turbidity is observed in either layer at the end of ten minutes (*acetylene*).

Agitate 20 cc. of trichloroethylene with a 50 cc. portion of water and repeat, using a 25 cc. portion of water; transfer the combined aqueous layer to a flask and add to the aqueous solution two drops of methyl red indicator solution: if the color of the solution is yellow, not more than 0.1 cc. of tenth normal hydrochloric acid is required to assume a pink color; if the color of the solution is pink, not more than 0.1 cc. of tenth normal sodium hydroxide is required to assume a yellow color.

Agitate 10 cc. of trichloroethylene with 25 cc. of water and allow the liquid to separate completely. Separate 10 cc. portions of the aqueous layer are affected as follows: No turbidity is noted five minutes after the addition of 0.1 cc. of nitric acid and 0.1 cc. of silver nitrate solution (*chlorides*); no blue color is observed after the addition of 0.1 cc. of potassium iodide test solution and 0.1 cc. of starch test solution (*readily oxidizing substances such as free chlorine*).

Add 0.1 cc. of alcohol to 5 cc. of trichloroethylene: a turbid solution is formed (*distinction from chloroform*).

Evaporate 25 cc. of trichloroethylene in a platinum or porcelain dish on a steam bath and dry to constant weight at 100 C.: No weighable residue is obtained.

Trichlorethylene-Calco.—A brand of trichloroethylene-N. N. R.

Manufactured by Calco Chemical Co., Inc., Bound Brook, N. J. No U. S. patent or trademark.

Tubes Trichlorethylene-Calco, 1 cc.

REPORTS OF THE COUNCIL

THE COUNCIL HAS AUTHORIZED PUBLICATION OF THE FOLLOWING REPORT.

W. A. PUCKNER, Secretary

FERRO-COPRAL TABLETS NOT ACCEPTABLE FOR N. N. R.

Ferro-Copral Tablets, proposed for use "whenever iron is to be used in the treatment of anemia," were presented for the Council's consideration by Brewer & Co., Inc. Each tablet is stated to contain: saccharated ferric oxide-N. F., 1 grain; manganese citrate, 10 grains; copper proteinate, one-fourth grain; cocoa and sugar q. s., 16 grains. The copper proteinate is stated to be prepared by interaction of egg albumin and copper citrate and is stated to contain from 4.6 to 4.7 per cent of copper (Cu).

Brewer & Company, Inc., submit no evidence of clinical trials carried out with their product. In the submitted advertising the firm emphasizes anything that favors the use of iron, copper and manganese, citing evidence dealing with animal experiments and some cases of clinical trials with copper and iron which do not constitute acceptable evidence for the value of the administration of copper and iron or of copper, iron and manganese. While reports of experiments have been published indicating the value of copper when added to a copper free diet, these do not prove that it has any value when added to ordinary diets that already contain copper. The latter is indeed improbable since it is necessary to take extreme precautions to exclude copper from foods in order to demonstrate that its addition has any effect. The evidence cited by the firm does not constitute conclusive proof of the value of such a product as Ferro-Copral Tablets containing iron, copper and manganese, and the implied claim that this combination is more efficacious than iron alone must be held an unwarranted therapeutic claim until positive clinical evidence for the value of the mixture over simple iron preparations becomes available.

Because of lack of originality, a proprietary name cannot be recognized for a mixture of saccharated ferric oxide, manganese citrate, and copper proteinate; the name "Ferro-Copral" is therefore objectionable.

The Council declared Ferro-Copral Tablets unacceptable for New and Nonofficial Remedies because it is marketed under a nondescriptive proprietary name and because the claims made for it are unwarranted.

Committee on Foods

THE FOLLOWING PRODUCTS HAVE BEEN ACCEPTED BY THE COMMITTEE ON FOODS OF THE AMERICAN MEDICAL ASSOCIATION FOLLOWING ANY NECESSARY CORRECTIONS OF THE LABELS AND ADVERTISING TO CONFORM TO THE RULES AND REGULATIONS. THESE PRODUCTS ARE APPROVED FOR ADVERTISING IN THE PUBLICATIONS OF THE AMERICAN MEDICAL ASSOCIATION, AND FOR GENERAL PROMULGATION TO THE PUBLIC. THEY WILL BE INCLUDED IN THE BOOK OF ACCEPTED FOODS TO BE PUBLISHED BY THE AMERICAN MEDICAL ASSOCIATION.

RAYMOND HERTWIG, Secretary.

CLOVERDALE MINERAL WATER (CARBONATED)

Manufacturer. — Cloverdale Spring Company, Newville, Cumberland County, Pa., and Baltimore, Maryland.

Description.—A bottled highly carbonated spring water of very low mineral content; free of pathogenic micro-organisms.

Manufacture.—The water is pumped from Cloverdale Springs through a wrought iron pipe line to the bottling plant and discharged into a glass lined tank, from which it is run through three different filters: a bed of fine sand, artificial stone, and five white filter papers. The sand filter is treated with chlorine solution each week and is inspected several times a month to assure that it is in good condition; if not, the sand is removed, washed, treated and replaced. The stone filter is treated with chlorine solution at least once a week. The filter papers are changed every day. The paper filters act as a check on the other filters and come off clean each day. The filtered water is refrigerated over block tin or german silver coils to 1 C., is carbonated to contain 4.7 volumes of carbon dioxide, and is delivered to the filling machine through a pure block tin pipe.

The bottles used are processed for twenty minutes in a 5 per cent solution of caustic soda at 82 C., drained, rinsed with pure water, drained, and immediately automatically filled and capped without contact with human hands.

Analysis (submitted by manufacturer).—

(Analysis of uncarbonated water)

	parts per million
Phosphate (PO_4)	trace
Metaborate (BO_2)	0.0
Arsenate acid (AsO_4)	0.0
Silica (SiO_2)	14.0
Sulphate (SO_4)	22.0
Carbonate (CO_3)	0.0
Bicarbonate (HCO_3)	99.0
Nitrate (NO_3)	trace
Nitrite (NO_2)	0.0
Chloride (Cl)	1.0
Bromide (Br)	0.0
Iodide (I)	0.0
Iron (Fe)	4.0
Manganese (Mn)	trace
Calcium (Ca)	29.0
Magnesium (Mg)	7.0
Potassium (K)	2.0
Sodium (Na)	trace
Ammonium (NH_4)	0.1
Oxygen (Calculated) (O)	0.2
(Sanitary analysis)	
Ammonia nitrogen	0.15
Albuminoid nitrogen	0.10
Nitrite nitrogen	0.002
Nitrate nitrogen	0.000
Oxygen consumed	2.0

Micro-Organisms.—

Colonies per cc. (37 C., 96 hours)	10
Colonies per cc. (25 C., 96 hours)	15
Gas producers (5 cc.)	0
B. coli-communis	absent
Streptococci	absent

Claims of Manufacturer.—A pure highly carbonated spring water of a low mineral content.

DEBUS SLICED BREAD AND DEBUS QUALITY BREAD

Manufacturer.—Debus Baking Corporation, Hastings, Neb.

Description.—A white bread made by the sponge dough method.

Manufacture.—The sponge dough ingredients, patent flour of Northwest wheat, water, salt, sucrose, yeast and a yeast food containing calcium sulphate, ammonium, chloride, sodium chloride and potassium bromate, are mixed in a high speed mixer. The sponge dough is fermented for from four to five hours, after which are added flour, water, salt, sucrose, lard, malt syrup, and sweetened condensed skim milk to make the completed dough, which is cut into pieces of desired weight. The pieces are fermented for a short time, molded into loaf form, panned, further fermented, baked for from thirty to thirty-five minutes, cooled, and wrapped in wax-paper.

The factory, equipment and storage rooms are kept in strictly sanitary condition.

Analysis (submitted by manufacturer).—

	per cent
Moisture (entire loaf)	34.7
Ash	0.9
Fat (direct ether extraction method)	1.1
Protein (N × 6.25)	9.1
Crude fiber	0.2
Carbohydrates other than crude fiber (by difference)	54.0

Calories.—2.6 per gram; 74 per ounce.

Claims of Manufacturer.—A bread of good quality.

BANNER BLUE CORN SYRUP WITH CANE FLAVOR

Packer.—D. B. Scully Syrup Company, Chicago.

Description.—A table syrup; corn syrup flavored with refiners' syrup.

Manufacture.—The corn syrup ingredient is manufactured from a purified corn starch. Corn is soaked in warm water containing 0.2 per cent sulphur dioxide until softened to enable the separation of the germ, hull, gluten and starch. The starch is repeatedly washed until almost completely free from the other materials.

The purified starch in 0.2 per cent hydrochloric acid suspension is cooked under pressure at about 140 C. until the starch has been sufficiently hydrolyzed to produce 43 per cent reducing sugars as dextrose on the basis of the solids content of the final product. The mixture is almost completely neutralized with sodium carbonate, which throws out of solution the protein and other nonsugar constituents. The hot sugar liquor is filtered through cloth filter presses, concentrated, and filtered through bone-black, yielding a water clear solution which is concentrated in "vacuum" pans to the desired density.

The manufacturing process is under laboratory control. The finished syrup has a p_H of 5.0 for mixing syrups and 5.5 for confection syrups. The ash consists essentially of sodium chloride.

A representative analysis of the corn syrup follows:

	per cent
Moisture	19.5
Ash	0.3
Protein (N × 6.25)	0.03
Reducing sugars as dextrose	34.6
Dextrins (by difference)	45.6
Sulphur dioxide	0.002
p_H	5.0

The refiners' syrup ingredient conforms to the United States Department of Agriculture Standard for that product.

The corn syrup and a relatively smaller quantity of refiners' syrup are heated to 80 C. and mixed together in a tank, which acts as a reservoir to the filling machines for packing the syrup in air tight tins.

Analysis (submitted by manufacturer).—

	per cent
Moisture	23.0
Ash	0.7
Fat (ether extract)	0.0
Protein (N × 6.25)	0.2
Reducing sugars, as dextrose	31.0–41.0
Reducing sugars, as dextrose after invertase inversion	40.0–50.0
Sucrose (estimated from reducing sugars)	8.0–11.0
Dextrins (by difference)	37.1–24.1
Sulphur dioxide	0.001

No methods are available for accurately determining the composition of syrups of this nature; therefore the foregoing analysis is roughly approximate.

Calories.—3.1 per gram; 88 per ounce.

Claims of Manufacturer.—A syrup for cooking, baking and table use. It is suitable as a carbohydrate supplement for milk modification for infant feeding.

HYGEIA PURE STRAINED MIXED VEGETABLES WITH RICE AND BEEF EXTRACT

Contains Vitamin D

Added Irradiated Ergosterol

Manufacturer.—Snider Packing Corporation, Rochester, N. Y.

Distributor.—Hygeia Nursing Bottle Company, Buffalo, N. Y.

Description.—A mixture of strained potatoes, carrots, celery and rice with beef extract prepared under conditions which largely retain the natural mineral and vitamin content; with added vitamin D (irradiated ergosterol), 60 D units per fluidounce; packed in glass jars. The D units are those defined by the Council on Pharmacy and Chemistry of the American Medical Association (New and Nonofficial Remedies, 1931, p. 414). One fluidounce is equivalent in vitamin D to the D content of one teaspoonful of cod liver oil. No sugar or seasoning is added.

Manufacture.—The potatoes are put through an onion peeler to remove the outer skin, are cleaned, and the eyes are cut out. The celery is cleaned and scrubbed by hand; the root, butt end and leaves are cut off and the stalks separated in order that each stalk may be washed separately and scrubbed. A definite quantity of water plus the ground potatoes, carrots and celery are placed in a tin lined steam jacketed kettle and heated to from 71 to 76 C. After fifteen minutes the beef extract is added. The batch is cooked for a definite period, when the boiled rice is added, after which the entire batch is cooked for five minutes.

The cooked vegetables are then passed through a puréeing device similar to that used for peas. All subsequent steps are similar to those described for the preparation of the Strained Peas (THE JOURNAL, Feb. 13, 1932, p. 555).

Irradiated ergosterol is incorporated in the product, as described for the Strained Peas.

Analysis (submitted by manufacturer).—

Specific gravity 20 C./20 C. 1.03

	per cent
Moisture	92.0
Total solids	8.0
Ash	0.5
Fat (ether extract)	0.1
Protein (N × 6.25)	1.0
Starch (acid hydrolysis method)	3.3
Crude fiber	0.4
Carbohydrates other than crude fiber (by difference)	6.0
Calcium (Ca)	0.02
Iron (Fe)	0.001
Phosphorus (P)	0.01

Calories.—0.3 per gram; 8 per ounce.

Vitamins and Claims of Manufacturer.—See these sections for Strained Peas.

CHECK BREAD

(Sliced and Unsliced)

Manufacturer.—Banner Baking Company, Birmingham, Ala.

Description.—A white bread made by the sponge dough method.

Manufacture.—The sponge dough ingredients, "short patent" flour from Southwest wheat, water, yeast and a yeast food containing ammonium chloride, calcium sulphate, sodium chloride and potassium persulphate, are mixed in a high speed mixer. The sponge dough is fermented for from four to five hours, after which are added flour, water, salt, sucrose, lard and powdered skimmed milk to make the completed dough, which is cut into pieces of desired weight. The pieces are fermented for a short time, molded into loaf form, panned, fermented, baked for from thirty to thirty-five minutes, cooled, and wrapped in wax-paper.

The factory, equipment and storage rooms for the materials used are kept in strictly sanitary condition.

Analysis (submitted by manufacturer).—

	per cent
Moisture (entire loaf)	37.2
Ash	0.9
Fat (direct ether extraction method)	1.9
Protein (N × 6.25)	10.0
Crude fiber	0.2
Carbohydrates other than crude fiber (by difference)	49.8

Calories.—2.6 per gram; 74 per ounce.

Claims of Manufacturer.—A bread of good quality.

SATURDAY, MARCH 5, 1932

DUODENAL ULCERS AFTER LOSS OF PANCREATIC JUICE

While, *a priori,* the total loss of any one of the digestive fluids should not prevent entirely the conversion of the foodstuffs to assimilable forms, the chemical characteristics of certain of these secretions, apart from the content of appropriate hydrolytic enzymes, are such that total loss is usually followed by grave consequences. McCaughan[1] has recently discussed the factors involved in the death resulting from complete drainage of pancreatic juice to the outside in experimental animals. It appears that, save for the terminal increase in urea of the blood, there is little demonstrable alteration in the blood, on chemical examination. The loss of water in the daily secretion of pancreatic juice, which amounts to from 300 to 450 cc., was thought to be an important factor in the fatal outcome. Pancreatic juice given by mouth in these studies had a beneficial effect, whereas intravenous injection of the juice or the dialysate from it proved ineffective. Other studies on the same theme but from a somewhat different point of view have lately been reported by Elman and Hartmann.[2] In this investigation an effort was made to determine the etiology of the peptic ulcers, which almost invariably occurred proximally to the pylorus in the duodenum after the total loss of pancreatic juice for a comparatively short time.

The animals were prepared for the experiment by ligation and subsequent intubation of the pancreatic duct. The external secretion of the entire gland was obtained in this way under sterile conditions and collected for the entire twenty-four hours. To avoid the fatal outcome of this procedure, intraperitoneal injections of 500 cc. of a solution containing sodium chloride, potassium chloride, calcium chloride, sodium lactate and dextrose were given each day. The animals were fed a mixed diet and remained in good condition. After intervals of from thirteen to eighteen days had elapsed, duodenal ulcers were found at necropsy. They were generally round or oval, frequently showed bleeding, and although perforation did not occur there was no evidence of healing. Abnormalities were not found in the stomach, pancreas or elsewhere in the body.

The absence of definite chemical changes in the blood leads to the conclusion that the main factor concerned in the development of the duodenal ulcers is not a general metabolic one. It appears that after gastro-enterostomy the development of peptic ulcers is frequent on the distal side of the exit from the stomach, irrespective of the portion of the small intestine to which it is joined, provided the pancreatic juice is not permitted to enter the intestine. Under ordinary circumstances there is evidence that the neutralization of the acid chyme takes place on the proximal side of the pyloric sphincter as a result of the regurgitation of the alkaline pancreatic juice. According to Elman and Hartmann the duodenal ulcers, in their studies, represent a local tissue erosion brought about by the acid material from the stomach. Supporting evidence is at hand that partial pyloric occlusion is followed by high gastric acidity and ulcers in the gastric mucosa.

These conclusions naturally direct attention to the normal mechanism of the opening of the pyloric sphincter. The recent review by Murlin[3] summarizes the conflicting evidence bearing on this question and the consequent difficulty in formulating a sound hypothesis. The foregoing discussion provides important supplementary information on the normal functions of this pyloric structure. It indicates that the opening of the pyloric sphincter is significant not only in permitting the egress of material but also in allowing the neutralizing fluids from the intestine and pancreas to enter the stomach, thus guarding the functional and structural integrity of both stomach and duodenum.

THE DISCOVERY OF THE TUBERCLE BACILLUS, 1882

The science of bacteriology is one of the youngest of the biologic disciplines on which the development of modern medicine rests. Bacteria were probably seen by the pioneer Leeuwenhoek before the end of the seventeenth century. Generations passed, however, before the beginnings of the remarkable progress that resulted in the formulation of the germ theory of disease. The doctrine of contagium vivum had, indeed, been proposed in earlier days; but it failed to take firm root and gradually disappeared from men's minds. There was some revival, after 1840, of the theory that contagious disease might be due to microscopic forms of life; but it remained for the great triumvirate—for the work of Pasteur, Koch and Lister—to build the firm foundation on which the present germ theory of disease rests.

March 24, the entire world of biologists and men of medicine will celebrate the fiftieth anniversary of a great event in the history of medicine—the discovery of the tubercle bacillus by Robert Koch in 1882. It formed the basis for an entirely new approach to the understanding of a disease that was not only baffling but also extremely devastating. The attack on a secret enemy or the defense against it is usually fraught with great difficulties. When its identity and location are ascertained, intelligent effort can supplant empiric undertakings in the plans for conquest. Important as the identification of the bacillus of tuberculosis is, this contribution is only one of many researches by Koch that attained the goal of success and have greatly promoted the development of medicine.

---

[1] McCaughan, J. M.: Am. J. Physiol. 97: 459 (June) 1931.

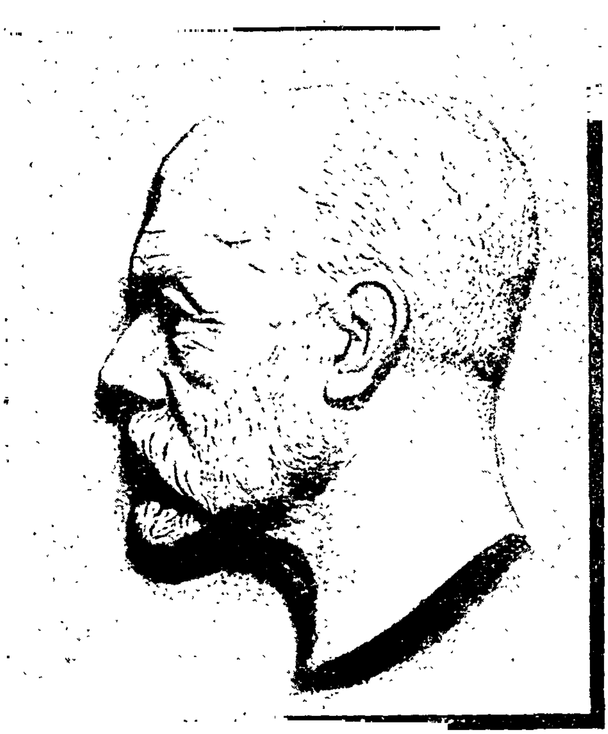
[2] Elman, Robert; and Hartmann, A. F.: Spontaneous Peptic Ulcers of Duodenum After Continued Loss of Total Pancreatic Juice, Arch. Surg. 23: 1030 (Dec.) 1931.

[3] Murlin, J. R.: J. Nutrition 2: 311 (Jan.) 1930.

In his volume on biology and its makers, Locy[1] has pointed out that Koch, with the rigorous scientific spirit for which he is noteworthy, established four necessary links in the chain of evidence to show that a particular organism is connected with a particular disease. These four postulates of Koch are, first, that a microscopic organism of a particular type should be found in great abundance in the blood and the tissue of the sick animal; second, that a pure culture should be made of the suspected organism; third, that this pure culture, when introduced into the body of another animal, should produce the disease; and, fourth, that in the blood and tissues of that animal there should be found quantities of the particular organism that is suspected of producing the disease. "Koch's postulates," establishing the pathogenic character of a given microorganism, were first outlined in the classic description of the finding of the tubercle bacillus.[2] Special methods of culture and staining were probably of help in the discovery. In Microbe Hunters, de Kruif,[3] in a chapter on Koch, pays his respects to

> the man who really *proved* that microbes are our most deadly enemies, who brought microbe hunting near to being a science, the man who is now the partly forgotten captain of an obscure heroic age.

Let us hope that before the centennial anniversary, in 1943, of the birth of this distinguished German savant, medicine, aided by his great discovery, will have secured a firm mastery over tuberculosis.



Robert Koch

NEW HAVEN'S PUBLIC HEALTH RECORD FOR 193

The medical profession is striving for the day when the well trained physician will enjoy fully the wholehearted and intelligent cooperation of the layman. Given such collaboration and the present achievements of the science of medicine, anxiety over the elimination of specific infectious diseases could probably be largely eliminated. In 1931, for the first time, New Haven was without a death from diphtheria and in this year there were only four cases of this disease, a new low record for this city of 162,670 inhabitants. Furthermore, this was the third year, in recent times, during which no death from scarlet fever has occurred. Not only were there forty-seven fewer cases of tuberculosis reported in 1931 than in the immediately preceding year, but the mortality rate was the lowest in history. Two epidemics were experienced, yet even in respect to these the death rates were unusually low; of 4,636 cases of measles only 2 were fatal, and there were 150 cases of poliomyelitis with 9 deaths, a rate much lower than that in the cities in the general vicinity of New Haven.

The record for health established in this community is important because of the methods whereby such distinction was attained. As with most noteworthy achievements, individual records of this sort represent the fruition of progressive improvement, not only national but world-wide. In regard to diphtheria, for instance, real progress in its eradication began with the establishment of the relationship between the diphtheria bacillus and the disease in 1884 by Löffler. There followed the demonstration of first the toxin, then later the antitoxin, and in 1910 Schick's studies, on which modern prophylaxis so largely rests. A general tendency to decrease in diphtheria has been noted. In New Haven the number of deaths per hundred thousand of population was 184 in 1877 and 130 in 1890; by 1910 it had fallen to 12.7. In 1920 there were 466 cases with 17 deaths, and in 1923 an active campaign was begun to root out this disease. The work was carried out for the most part in the schools and up to the middle of 1931 the toxin-antitoxin treatment had been administered to 35,496 children. Of these, 11,936 had received treatment previously as babies or preschool children. In addition, the Schick test showed that 13,739 individuals were already protected aganist diphtheria. Whereas for the ten years prior to the beginning of this work in 1923 the average number of cases was 313 a year with 20 deaths, the number of cases of diphtheria in 1930 was 14, with 1 adult death. The past year, with only 4 cases and no deaths, completes a remarkable record of preventive medicine on a large scale. The 49,235 children who have been treated not only were protected against the disease but have taken part in a public health demonstration of national importance.

Vital statistics similar to these are available for many cities in this and other countries. They are the occasion for a feeling of civic pride on the part of those who read them; they represent, to a relatively small group of workers, dear results obtained after many discouragements, especially during unfavorable times; they indicate to many citizens a new appreciation of the power of knowledge and the value of preventive medicine; finally, such data mean more effective cooperation with the physician on the part of the layman. Not the least value in an accomplishment of this kind is the incentive and example for similar attacks on other diseases.

Current Comment

WHAT IS BONE?

Every beginner in physiology knows that bone consists of water and about equal parts of organic and inorganic material. If he has had some chemical training he has learned to identify the organic basis of bone with the albuminoid collagen, the precursor of gelatin. He is surely aware, too, that bone is rich in the elements calcium and phosphorus. This mineralization of the osseous tissue serves at once to explain the rigidity of the structures that form the skeleton and thus determine to some extent the form of the body. The more detailed studies of recent years have demonstrated, however, that the inorganic make-up of bone is not adequately expressed by the assumption that it consists of calcium phosphate. The application of the newer methods of roentgen analysis, such as the chemist now applies to the study of crystals, indicates that bone has a crystalline structure which may be compared with that of the apatite minerals. According to Roseberry, Hastings and Morse[1] of the University of Chicago, the chemical composition of untreated bone is similar to that of the mineral dahlite. This has been verified by Bogert and Hastings[2] in the same laboratories. The chief inorganic constituent of bone is probably a crystalline salt, $CaCO_3.nCa_3(PO_4)_2$, n approximating the value 2 in untreated bone. This new information may serve to throw light on the factors governing the precipitation of calcium salts from body fluids not only in normal bone formation but in such pathologic deposits as calcified tissues, hardening of the arteries and gallstones. The bones are looked on today not only as structural parts of the body but also as storehouses of calcium. This element can easily be laid down in the skeleton and easily removed. The mineral ingredients are in a state of flux. Obviously the mobilization of this element from the skeletal units must be determined or modified to some extent by the nature of the inorganic sources in the bones. The newer knowledge also indicates that many tissues, but especially bone, contain an enzyme, phosphatase, that can liberate phosphate from hexose phosphate widely present in the body. It probably plays some part in bringing about a local increase in phosphate ions and thereby facilitating the deposition of calcium phosphate in growing bone. The story of the chemistry of bone is thus growing into a larger chapter of biochemistry.

THE BACTERIA OF FOOD POISONING

Reports of cases of food poisoning are interesting, especially if the allegedly causative organism has been isolated from the food, from the excreta of persons ill or, perhaps, more rarely, from both. Geiger[1] and his associates have recently reported three outbreaks, two of which occurred in hospitals. The organisms isolated were B. enteritidis, B. paratyphosus B (Aertrycke type) and B. paratyphosus A. The contaminated foods were incompletely cooked veal, rice pudding and an egg soufflé, respectively. It is particularly important to note the absence of infections, as would be indicated by prolonged fevers, in the outbreak apparently due to B. paratyphosus A, in which the food was contaminated by a carrier, the assistant chef of the hospital. That outbreaks of food poisoning may be caused by the paratyphoid-enteritidis group of organisms only has been long questioned by workers in this field. Seemingly, many organisms may be isolated that do not lend themselves to serologic classification with the well known members of the accepted groups. In fact, the isolation of organisms so general in nature as B. proteus and many others closely allied in type from food involved in outbreaks may lead public health officials astray in interpreting the causative factors. Furthermore, the involving of the cocci group, notably the staphylococcus, by Jordan[2] and his co-workers, may further confuse the situation. The evidence seems clear, however, that this organism, so universal and so closely associated with the human skin and therefore with the preparation of food, may be isolated and, in suitable medium, produce a poison that is a gastro-intestinal irritant in man. The significance of the staphylococcus and of other organisms that may be isolated from foods suspected of causing outbreaks may be accepted as sufficient. Presumably the clinical symptoms described as well as the incubation period of the intoxication from bacterially contaminated food are similar in all outbreaks, despite the specific organism responsible.

Association News

ABSTRACT OF MINUTES OF BOARD OF TRUSTEES HELD AT ASSOCIATION HEADQUARTERS, FEB. 18 AND 19, 1932

A meeting of the Board of Trustees was held at the Association headquarters, Feb. 18 and 19, 1932.

APPOINTMENTS OF REPRESENTATIVES

Dr. Dean Lewis, Baltimore, was appointed to serve as the Association's representative on the Committee on Autopsies, under the auspices of the American Hospital Association.

Dr. E. P. Sloan, Bloomington, Ill., was appointed to represent the Association at the second International Conference on Goiter, which will be held in Bern, Switzerland, in August, 1933.

THIRD INTERNATIONAL CONFERENCE ON GOITER TO BE INVITED TO THE UNITED STATES

It was decided to add the Association's invitation to the invitations of other national bodies in the hope that the third International Congress on Goiter may be held in the United States in 1937.

ELECTIONS

Nominations to fill vacancies on the editorial boards of the special journals, on councils and on committees were considered and the following appointments were made:

Drs. Isidore Friesner, Ludvig Hektoen, Frederick Tilney, Wallace I. Terry, George M. MacKee and Fritz Talbot were elected to succeed themselves on the editorial boards of the *Archives of Otolaryngology, Archives of Pathology, Archives of Neurology and Psychiatry, Archives of Surgery, Archives of Dermatology and Syphilology* and the *American Journal of Diseases of Children*, respectively.

Dr. J. D. Heard, Pittsburgh, was elected to succeed Dr. Joseph L. Miller on the editorial board of the *Archives of Internal Medicine.*

Dr. Sanford R. Gifford was named to succeed himself, and Dr. Walter R. Parker to succeed Dr. George S. Derby (deceased) on the editorial board of the *Archives of Ophthalmology.*

Dr. C. C. Bass was appointed to succeed himself on the Committee on Scientific Research.

Dr. Reid Hunt and Dr. W. W. Palmer were elected to succeed themselves, and Dr. Alfred F. Hess, New York, to succeed Dr. A. J. Carlson on the Council on Pharmacy and Chemistry.

Dr. Charles A. Doan, Columbus, Ohio, was appointed to succeed Dr. William F. Petersen on the Division of Medical Sciences, National Research Council.

RESIGNATION OF DR. FRANCIS CARTER WOOD FROM COUNCIL ON PHYSICAL THERAPY

The Board accepted with regret the resignation of Dr. Francis Carter Wood from the Council on Physical Therapy, the tendering of which was made necessary because of the burden that has been placed on his time by his duties as editor of the *American Journal of Cancer.*

BUREAU OF HEALTH AND PUBLIC INSTRUCTION

Dr. John M. Dodson, who has acted in the capacity of director of the Bureau of Health and Public Instruction over a period of years, was retired on account of ill health.

Dr. W. W. Bauer, who has recently been employed to act as assistant director of that bureau, was made director.

SURVEY OF HOSPITALS FOR THE CARE OF NERVOUS AND MENTAL PATIENTS

The Board approved the employment of a trained psychiatrist to analyze the information procured through the questionnaire sent out by the Committee on Mental Hygiene and through other sources, with a view to the preparation of a report and the adoption of certain standards.

TESTIMONY OF DR. BEVAN BEFORE SENATE COMMITTEE

The Board of Trustees approved the editorial in THE JOURNAL concerning the testimony of Dr. Arthur Dean Bevan before a Senate committee, and instructed the editor so to inform Dr. Bevan.

MISCELLANEOUS

Appropriations were made to carry on the work of the various councils and bureaus, as well as for the Committee on the Protection of Medical Research and for the committees on scientific and therapeutic research. Other more or less routine matters were given careful consideration.

THE NEW ORLEANS SESSION

Indications Point to Well Attended Meeting

Reports received from Dr. W. H. Seemann, general chairman of the Committee on Arrangements for the New Orleans Session of the American Medical Association, May 9 to 13, indicate a large attendance. Advance hotel reservations are being received in large numbers by the New Orleans Hotels Committee, of which Dr. Emmett L. Irwin is chairman.

Dr. Irwin reports that the Hotel Roosevelt is booked to capacity with advance reservations and has been obliged to turn a number of requests for rooms over to his committee for placement with other New Orleans hotels. A large number of reservations have already been placed with the St. Charles and Monteleone, and scattering reservations have been handled through all the larger hotels of New Orleans.

The New Orleans committee assures adequate housing facilities through its large number of fine hotels. The convention city's hotel committee urges, however, that for choice of accommodations members should mail requests for reservations without delay. A list of hotels with rates appeared on advertising page 41 of THE JOURNAL, February 6. Hotel reservations should be mailed to Dr. Emmett L. Irwin, Chairman, Hotels Committee, Post Office Box 1460, New Orleans, La.

Women's Auxiliary Planning Entertainments

Mrs. Walter J. Freeman, president of the Women's Auxiliary of the American Medical Association, visited New Orleans, February 25 and 26, and met with the local committee, of which Mrs. Joseph Hume is chairman. The Hotel Bienville has been designated as headquarters for the Women's Auxiliary, and plans are materializing for what promises to be one of the most enjoyable entertainment programs ever arranged for the Women's Auxiliary. Mrs. Hume points out that New Orleans holds so much of interest, particularly to womankind, that the only difficulty existing in planning the entertainment program is to find time to include opportunities for observing the many historical and romantic points of interest, beautiful gardens of semitropical and native flowers, interesting old patios, and the other innumerable attractions of the South's metropolis.

MEDICAL BROADCAST FOR THE WEEK

American Medical Association Health Talks

The American Medical Association broadcasts on Monday from 12 noon to 12:05 p. m. over Station WBBM (770 kilocycles, or 389.4 meters) and other stations of the Columbia Broadcasting System, and on Wednesday and Friday from 2:25 to 2:30 p. m. over Station WBBM, Chicago.

The program for the week is as follows:

March 7. Principal Causes of Illness in Typical American Community.
March 9. Common Sense and the Open Window.
March 11. Why We Run Away.

There is also a fifteen minute health talk sponsored by the Association on Saturday from 11:15 to 11:30 a. m. over Station WBBM, Chicago.

The program for the week is as follows:

March 12. The Sign on Your House.

Medical News

(Physicians will confer a favor by sending for this department items of news of more or less general interest: such as relate to society activities, new hospitals, education, public health, etc.)

CALIFORNIA

Diploma and Certificate Missing.—Dr. Paul P. E. Michael, a graduate of McGill University, May 30, 1928, licensed as a physician and surgeon in California, Aug. 30, 1928, reported, February 2, that his California certificate (number A-04771) was recently lost along with other things when a bag of his disappeared. A diploma from Northwestern University Medical School, 1904, belonging to Dr. Claire Willard Fulton, Los Angeles, was stolen from his office, February 7.

University News.—Dr. John C. Meakins, professor of medicine and director, department of medicine, McGill University Faculty of Medicine, will be at the University of California Medical School as university lecturer from March 11 to April 2. The university lectureship was established at the medical school in 1930. Dr. Lewellys F. Barker, Baltimore, was the first lecturer, and Dr. Herman M. Adler, the second. The physician serving as lecturer conducts clinics and demonstrations at the medical school during his month's incumbency.

COLORADO

Licenses Renewed.—At a recent meeting of the state board of medical examiners, the license of Dr. Silvius S. Craig, Wilmar, Calif., was renewed. Dr. Craig's license had been revoked, July 1, 1930, for unprofessional and dishonorable conduct in advertising. The license of Dr. Toros Sarkisian, Denver, was renewed at a meeting of the board, January 5. Dr. Sarkisian's license had been revoked in 1923 for performing an abortion.

White House Conference.—A continuation committee, appointed at the last session of the Colorado White House Conference on Child Health and Protection, Denver, January 14-16, is now endeavoring to discover ways by which the findings may be used to guide future activities in the different counties of the state. F. J. Kelly, Ph.D., Washington, D. C., representing the national conference, and Dr. Estella F. Warner, U. S. Public Health Service, were the guest speakers. Dr. Franklin P. Gengenbach, Denver, was director of the conference. The chairmen of the four divisional sessions were: medical service, Dr. Maurice H. Rees, Denver, president, Colorado State Medical Society; public health service and administration, Dr. Samuel R. McKelvey, Denver, secretary, state board of health; education and training, Mrs. Inez Johnson Lewis, state superintendent of public instruction; the handicapped, Miss Eunice Robinson, president, state conference of social work.

DISTRICT OF COLUMBIA

Cancer Clinic.—Dr. Joseph C. Bloodgood and his associates at Johns Hopkins University School of Medicine and Johns Hopkins Hospital, Baltimore, conducted a bone and cancer clinic in the department of pathology, Howard University School of Medicine, February 19-20.

Personal.—At the bicentennial convocation of George Washington University, February 22, the honorary degree of doctor of laws was conferred on Dr. Luther Halsey Reichelderfer, and the degree of doctor of science on Dr. Sterling Ruffin. Both physicians, who are residents of Washington, are alumni of George Washington University School of Medicine.

Dr. Allemann Retires.—Dr. Albert Allemann retired at the end of February from active duty in the library of the surgeon general's office, where he has been since 1900. Dr. Allemann was born in Soleure, Switzerland, in 1860, and came to the United States in 1884. He entered the library in 1900 and began the study of medicine, graduating from George Washington University School of Medicine in 1904. Dr. Allemann was for fifteen years principal assistant librarian and editor of the *Index Catalogue*. At one time he was assistant editor of the *Index Medicus* and later was on the staff of the *Quarterly Cumulative Index Medicus*. Dr. Allemann will be remembered for his editing on the *Index Catalogue*, including four volumes of the second and all of the third series. Testimonials of the esteem and affection of his fellow workers at the library were presented to Dr. Allemann at the time of his retirement.

Annual Banquet of Society.—Dr. E. Starr Judd, Rochester, Minn., President of the American Medical Association, was the guest speaker at the annual reunion of the George Washington University Medical Society, February 20. His subject was "Research and Practical Studies of Diseases of the Biliary Tract." Among the other guests of honor were Cloyd Heck Marvin, LL.D., president of George Washington University; Dr. Earl Baldwin McKinley, dean of George Washington University School of Medicine; Dr. Alan M. Chesney, dean, Johns Hopkins University School of Medicine; Dr. William Gerry Morgan, dean, Georgetown University Medical School; Surg. Gen. Robert W. Patterson, U. S. Army; Surg. Gen. Charles E. Riggs, U. S. Navy; Surg. Gen. Hugh S. Cumming, U. S. Public Health Service; Dr. Luther H. Reichelderfer, chairman, board of commissioners of the District of Columbia, and Dr. Joel T. Boone, physician to President Hoover. Dr. Frederick A. Reuter, president of the society, presided.

Society News.—The International Medical Club gave a dinner, February 4, in honor of Dr. Georges Portmann, professor of laryngology, University of Bordeaux. At a business meeting later, Dr. Adolphus B. Bennett was elected president, and Dr. Panigiotes S Constantinople, secretary.——The Washington Society of Pathologists furnished the program for the meeting of the Medical Society of the District of Columbia, January 27. Major George R. Callender, Baltimore, spoke on "Prognosis of Melanoma of the Eye"; Dr. Wallace M. Yater, Major Paul E. McNabb and Dr. Edmund Horgan, "Clinicopathologic Types of Hemochromatosis," and Dr. Walter Freeman, "Cerebral Metastases in Primary Carcinoma of the Lung."——Dr. Francis R. Hagner addressed the Society of Hospital Interns, January 13, on "The Use and Abuse of the Catheter."——The Hippocrates-Galen Medical Society furnished the program for the February 17 meeting of the Medical Society of the District of Columbia; among others, Dr. George B. Trible spoke on "Present Status of Sims Surgery."

ILLINOIS

Society News.—Dr. Francis Eugene Senear, Chicago, addressed the Will-Grundy County Medical Society, March 2, on the present status of antisyphilitic treatment.——The Aurora Medical Society was addressed, March 3, by Dr. Lowell D. Snorf, Chicago, on "Complications of Peptic Ulcer."

Chicago

Dr. Campbell to Give Gehrmann Lectures.—Dr. Charles Macfie Campbell, professor of psychiatry, Harvard University Medical School, will deliver the Gehrmann Lectures at the University of Illinois College of Medicine, March 15-17, in room 221 of the new building at 1853 Polk Street. The lectures will be devoted to mental hygiene. Dr. Campbell will speak at 4 o'clock, March 15, on "Schizophrenic Disorders"; March 16, 1 o'clock, "Preoccupation and Environmental Problems of the Patient," and, March 17, 4 o'clock, "Personal and Environmental Problems and Resources Available for Treatment."

Personal.—Mr. Paul H. Fesler has been appointed superintendent of Wesley Memorial Hospital, effective May 1, to succeed the late Mr. E. S. Gilmore. Mr. Fesler has been superintendent of the University of Minnesota Hospitals, Minneapolis, since Jan. 17, 1927. For twelve years previous to that time, he had served in a similar capacity at the University of Oklahoma. Mr. Fesler, for a number of years, was secretary of the Oklahoma Hospital Association, and at one time its president. He also served as president of the Minnesota Hospital Association. He is now president of the American Hospital Association.——Dr. James W. Hall was appointed criminologist on the coroner's staff, December 17.

New Regulations at Medical School.—Graduation in medicine eight years after entering college, instead of the present nine years, will be possible at the School of Medicine of the Division of Biological Sciences, University of Chicago, with the beginning of the spring quarter, according to regulations approved at a meeting of the faculty of the division, February 18. The intern year will be included in the eight years. Abolishment of the bachelor of science degree as an admission requirement was also approved. For admission to the medical school, adequate training in physics, chemistry, biology and mathematics is recommended, in addition to a reading knowledge of German or French. After 1933, a reading knowledge of German will be required. It is expected that this preparation will ordinarily be completed in the first year in the division. Selection by the committee on admissions will be based on character, aptitude and scholarship. Evidence of interest and ability in research will commend applicants to this committee. Requirements for the granting of the degree of doctor of medicine, as approved at this meeting, provide that group examinations be abandoned and general departmental examinations be substituted for them. The student will be required to pass a general departmental examination in each department during the quarter in which he completes his work in that department. The requirement of a thesis for graduation is abolished. The degree of doctor of medicine with honors in one department will be given when, in addition to meeting with distinction the requirements for the degree of doctor of medicine, the student has also completed a satisfactory thesis constituting a contribution to knowledge. This degree will be awarded on recommendation of the department and approval of the faculty of the division. The official name of the medical school will be the School of Medicine of the Division of the Biological Sciences.

Society News.—The Chicago Society of Industrial Medicine and Surgery held a joint meeting with the Chicago Urological Society, March 2; Drs. Kellogg Speed and Edward William White spoke on "Pelvic Fractures" and "A Study of Certain Urological Complications Associated with Pelvic Fractures," respectively.——Dr. Arthur Weil addressed the Chicago Society of Internal Medicine, February 22, on "Presence of Myelolytic Substances in the Urine of Multiple Sclerosis Patients" and Dr. Oswald H. Robertson and Helen M. Wallace, "Distribution of Pneumococci in Lungs During Lobar Pneumonia."——The Chicago Pediatric Society was addressed, February 15, among others, by Drs. Benjamin Gasul and Philip Rosenblum on "An Attempt to Use the Spinal Fluid as a Biologic Test for the Diagnosis of Tuberculous Meningitis."——Dr. John A. Larson, among others, spoke before the Chicago Neurological Society, February 18, on "Postural Precedence in Postencephalitis."——The Society of Medical History of Chicago was addressed, March 1, by Dr. Arno B. Luckhardt on "History of Hemostasis," and Dr. P. Arthur Delaney, "Michael Servetus and the Discovery of the Pulmonary Circulation." There was also an exhibition of old medical books in Billings Library, University of Chicago.——Dr. Stanton K. Livingston, Hines, Ill., among others, addressed the Chicago Orthopedic Club, February 12, on "Maggot Treatment of Chronic Osteomyelitis."——Dr. Tadeus Dundulis addressed the Lithuanian Medical Association of America, February 23, on "Elbow Fractures Treated in Extended Position."——A symposium on mucin therapy will comprise the program of the Chicago Medical Society, February 16; members of the faculty of Northwestern University Medical School will conduct the program.——Dr. Austin A. Hayden, among others, will address the Chicago Laryngological and Otological Society, March 7, on "Medical Advertising."——The Chicago Surgical Society was addressed, March 4, among others, by Drs. Loyal Davis and Hale A. Haven on "Surgical Treatment of Trigeminal Neuralgia," and Charles B. Huggins, "Further Experiments on Bone Formation."——Dr. Edward H. Cary, Dallas, Texas, President-Elect, American Medical Association, addressed the students and faculty of the University of Illinois College of Medicine, February 26, on "Medical Education, Past and Present."

INDIANA

New Biologic Collection.—The discovery and collection of nearly 700 biologic species of insect life new to science were announced on the return to Indiana University, Bloomington, of Alfred C. Kinsey of the zoology department from a 10,000 mile scientific trip through Mexico. The Kinsey expedition collected more than 100,000 individual specimens.

University News.—The department of medicine of Indiana University School of Medicine, Indianapolis, has been divided into two sections to be known as the department of cardiology and the department of internal medicine, according to the press, January 30. This reorganization was necessary to take care of steadily increasing work, it was said. Dr. George S. Bond will head the department of cardiology, and Dr. James O. Ritchey the department of internal medicine. Both of these physicians were on the staff of the former department of medicine.

Society News.—The Marshall County Medical Society was addressed at Plymouth, February 3, on "Treatment of Sinusitis."——Dr. Foster J. Hudson, Indianapolis, addressed the Hancock County Medical Society, February 12, on "Toxemias of Pregnancy: Threatened, Incomplete and Inevitable Abortion."——At the meeting of the Madison County Medical Society in Anderson, February 15, Dr. Heyworth N. Sanford, Chicago, spoke on "Convulsions in Infancy" with especial reference to treatment.——Dr. Edgar F. Kiser, Indianapolis, addressed the Delaware-Blackford County Medical Society, February 16, on "The History of Medicine."——Dr. Louis H. Clerf, Philadelphia, addressed the Tippecanoe County Medical Society, February 11, on "Bronchoscopic Aid in Diagnosis and Treatment."——The Floyd County Medical Society was addressed, February 12, by Dr. Elihu P. Easley, New Albany, on "Relation of Doctors to Each Other and to the Public."——Dr. Charles O. McCormick addressed the Indianapolis Medical Society, February 23, on "Fewer and Better Babies (From the Viewpoint of Eugenic Sterilization)," and Dr. Delbert O. Kearby, "Bronchoscopy as an Aid to Diagnosis."

KENTUCKY

Bills Introduced.—S. 350, to amend the nursing practice act, proposes to require all nursing of the sick to be done by a registered or trained nurse, except (1) gratuitous nursing "by a friend or member of the family"; (*2*) "strictly charitable nursing by established hospitals"; (3) services of "nurses who do not assume to be trained or registered nurses, who shall have had ten years practical nursing of the sick at the time of the passage of this act." Further, the bill proposes to make it "unlawful for any doctor or hospital . . . to employ or use any nurse unless that nurse be a registered or trained nurse." S. 353 proposes to create a board of barber and beautician examiners and to regulate the practice of barbering and beauty culture. S. 360 proposes to make it unlawful for any person to possess, sell, manufacture or distribute in any other than its natural state, any marihuana, Indian hemp or hasheesh, "except under the direction and in the course of treatment by a licensed physician." S. 374 and H. 724 propose to levy on licensed physicians a tax of one third of their fees for issuing prescriptions for intoxicating liquors or for narcotic drugs. S. 395 and H. 635, to amend the workmen's compensation act, propose to make an employer liable without any limit, other than the discretion of the compensation board, for such medical, nursing and hospital services as are necessary during the first ninety days after an injury to an employee. H. 521, to amend the laws defining the duties of coroners, proposes (1) to give coroners jurisdiction in cases of deaths occurring without medical attention; (*2*) to make it the duty of any person discovering or having in his possession the body of a person violently killed or dying without the attendance of a licensed physician to notify the coroner of the facts, and (3) apparently, to permit coroners to hold inquests without juries. H. 617, to amend the workmen's compensation act, proposes (1) to make the employer liable without any limit as to amount or time for such medical and hospital services as are necessary to treat an injured employee, and (2) to permit an injured employee to select his own physician.

MARYLAND

Child Health Activities.—About 25 per cent more children were examined last year at child health conferences in the counties throughout Maryland than in 1930. Dr. James H. Mason Knox, Jr., chief, bureau of child hygiene, state department of health, announced that a total of 8,423 children under school age, representing more than 5,000 families, were examined in 1931, as compared with 6,169 in the preceding year. Of the 8,423 children, 3,797 were under 5 years old, and the remainder from 5 to 7 years old. Including the stops made by the "healthmobile" in a tour of the Eastern Shore and southern Maryland last year, 388 different places were visited by health officers and 545 health conferences were held.

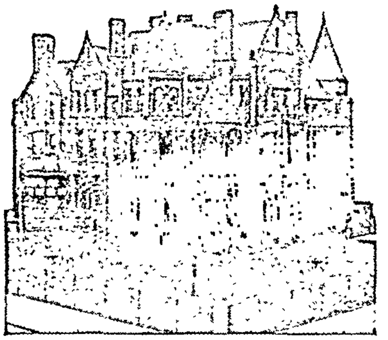
MICHIGAN

Society Opposes "Sheppard-Townerism."—The council of the Wayne County Medical Society recently adopted a resolution opposing further "Sheppard-Townerism." This action followed the recent introduction in Congress of two bills (H. R. 7525, S. 572) intended to revive "Sheppard-Townerism." These bills propose to appropriate money from federal taxes, raised largely from city populations, and apply it for rural hygiene generally and maternal and infant hygiene more particularly, in the rural districts of the various states.

Society News.—A symposium on tuberculosis in pregnancy comprised the program of a joint meeting of the Wayne County Medical Society and the Detroit Obstetrical and Gynecological Society, February 23; the speakers were Drs. Richard H. Morgan, William A. Hudson, Plinn F. Morse and Harold Henderson. The county society held "open house," February 22, in honor of Washington's anniversary.——Dr. John J. Corbett, Detroit, addressed the Macomb County Medical Society, January 4, on "Treatment of Hemorrhoids."——Drs. Wadsworth Warren, Jr., and Arthur E. Hammond, Detroit, addressed the Oakland County Medical Society, February 18, at Pontiac, on bronchoscopy. A film on "Vaginal Hysterectomy" was also shown.

Foundation Aids Study of Morphine.—The Rockefeller Foundation has provided for an extension of an investigation of the chemistry and pharmacology of morphine, with the object of removing the dangerous properties of the drug. This study has been carried on at the Universities of Michigan and Virginia, under the auspices of the National Research Council through its drug addiction committee. The Ann Arbor *Tribune* states that the results already obtained have been so promising that the foundation has granted a sum that will not only provide for the extension of the work to Jan. 1, 1936, but also allow some increase in the yearly budget. Drs. Charles W. Edmunds and Nathan B. Eddy are in immediate charge of the work at the University of Michigan.

Wayne County Society's New Home Dedicated.—The new headquarters of the Wayne County Medical Society, Detroit, was dedicated with a housewarming, January 29. More than 1,200 of the approximately 1,600 members of the society were present. The new home of the society contains fifty rooms. In 1893, a year of depression, the society's bulletin states, the expenditures for the building were said to be $400,000 for the house, $250,000 for decorations and glazing, and $300,000 for art treasures. The house, which was built by Mr. David Whitney, took four years to erect. The mansion is famous for its carved woodwork and parquet floors, its stained glass windows and its twenty fireplaces, each of different marble or tinted brick. The first floor of the building has been given over to the committee rooms, lounges and dining rooms of the society. The second floor contains the executive offices together with the offices of the Detroit Physicians Business Bureau, the collection department of the society. The smokers' room and the billiard and ping-pong room will occupy paneled space in the basement. A new feature of the society's headquarters is the Seniors' Room, set aside for physicians who have been in practice more than twenty-five years. The Noon Day Study Club, composed of physicians under 40 years of age, also occupies space in the building. Elaborate entertainment was provided at the housewarming and forty-three valuable door prizes were awarded. The Wayne County Medical Society had occupied its home in the Maccabees Building for five years.



MINNESOTA

Liquor Prescribing in Minnesota.—The Winona, Minn., *Republican Herald* cites an interview with S. B. Qvale, district superintendent of the Bureau of Industrial Alcohol in Minneapolis, in which he says that the total number of permits in Minnesota is 1,600. Of those who have permits, few physicians use the limit. Some physicians keep their books for two or three years without completely using them, and less than 7 per cent of physicians in the state use the full number of prescriptions allowed.

NEBRASKA

Health at Omaha.—Telegraphic reports to the U. S. Department of Commerce from eighty-three cities with a total population of 36 million, for the week ended February 20, indicate that the highest mortality rate (21) appeared for Omaha and the rate for the group of cities as a whole, 12.5. The mortality rate for Omaha for the corresponding week last year was 13.7. The annual rate for the eighty-three cities for the seven weeks of 1932 was 12, as against a rate of 14.4 for the corresponding period of 1931. Caution should be used in the interpretation of weekly figures, as they fluctuate widely. The fact that some cities are hospital centers for large areas outside the city limits or that they have large Negro populations may tend to increase the death rate.

Society News.—The Nebraska section of the American College of Surgeons held its annual assembly in Omaha, February 23-24. Among speakers listed on the program were Drs. Frank C. Mann, Rochester, Minn., who spoke on "Physiology of the Biliary Tract"; William E. Lower, Cleveland, "The Prostatic Problem"; Vilray P. Blair, St. Louis, "Surgery of the Ocular Appendages and Related Structures," and Louis J. Hirschman, Detroit, "Umbilical Colostomy in Carcinoma of the Rectum."——Drs. William L. Shearer and Rodney W. Bliss, Omaha, addressed the Otoe County Medical Society, Nebraska City, January 11, on "Upper Respiratory Infection."——Drs. Frederick W. Niehaus and John P. Lord, Omaha, addressed the Omaha-Douglas County Medical Society, February 9, on "Cardiac Enlargements with Special Reference to Orthograms" and "Deformities and Disabilities of the Lower Extremities," respectively.

NEW JERSEY

Society News.—Dr. Thomas McCrae, Philadelphia, addressed the Mercer County Medical Society, in January, on "Troubles of the Colon."——Dr. Frederick T. Van Beuren, Jr., New York, presented a paper before the Morris County Medical Society at the New Jersey State Hospital, Greystone Park, January 21, on "Symptoms of Acute Intestinal Obstruction with Relation to Other Acute Surgical Conditions of the Abdomen."——Drs. Matthew Walzer and Albert F. R. Andresen, Brooklyn, addressed the Passaic County Medical Society, Paterson, January 14, on "Allergy of the Respiratory Tract" and "Allergy of the Gastro-Intestinal Tract," respectively.——Dr. John A. Kolmer, Philadelphia, addressed the Gloucester County Medical Society, Pitman, January 22, on "Specific Treatment of Pneumonia."

Bills Introduced.—S. 189 proposes (1) to require every motor vehicle to be covered by adequate indemnity insurance and (2) to permit all persons injured by motor vehicles without regard to the negligence of either party, to recover specific amounts from the insurers of the motor vehicles causing the injuries. The indemnity recoverable is to include "indemnity for medical, surgical, hospital and nursing services, and the cost of medicines and appliances, actually incurred as a result of the accident." A. 215, to amend the workmen's compensation act, proposes to eliminate the statutory definition of hernia as ordinarily a disease and only rarely an accident, and as presumptively of either congenital or slow development in the absence of a tear or puncture of the abdominal wall. Proof of the industrial origin of a hernia may be by preponderance of evidence and need not as at present be conclusive proof. Time for the manifestation of symptoms after the event alleged to have caused the injury, within which industrial origin is to be presumed, is extended. Detailed provisions of the present law defining the relative responsibilities of employer and employee for the treatment of an industrial hernia will be eliminated if this bill is passed.

NEW YORK

Society News.—Dr. William H. Park, New York, addressed the Medical Society of the County of Rensselaer, January 12, on prevention of diphtheria, scarlet fever and poliomyelitis. Dr. Eugene F. Connally, Troy, retiring president, presented a paper on Welch bacillus infection.——Dr. Joseph C. Doane, Philadelphia, addressed the Broome County Medical Society, Binghamton, January 5, on "Relations Between the Medical and Nursing Professions and the Hospitals."——Dr. Harry R. Lohnes, Buffalo, presented a paper on "Anemia in Infancy and Childhood" before the Genesee County Medical Society, Batavia, January 13.

Prizes for Essays.—The Medical Society of the State of New York announces two prizes to be awarded this year. The Merritt H. Cash Prize will be given to a member of the state society who submits the best original essay on a subject to be designated by the committee on prize essays. This prize, established in 1863, has been awarded only four times. The second prize is the Lucien Howe Prize, a medal to be given for the presentation of the best original contribution to the knowledge of surgery, preferably ophthalmology. Competitors need not be members of the New York society. Essays must be submitted before May 9, to the Committee on Prize Essays, Medical Society of the State of New York, 2 East One Hundred and Third Street, New York. Members of the committee are Drs. Edwin MacD. Stanton, Schenectady, Albert C. Snell, Rochester, and Edgar A. VanderVeer, Albany.

Bills Introduced.—S. 959 and A. 1168 propose that the state commissioner of health assume and continue the functions of the bureau of venereal diseases in the state department of health. S. 1083 and A. 975, to amend the medical practice act with respect to the practice of osteopathy, propose (1) to denominate osteopaths as osteopathic physicians; (2) to provide that "a license to practice osteopathy shall not entitle the holder thereof to perform any surgical operation involving incision for the opening of a natural body cavity, for the removal of cancer or other tumor, for the amputation of an extremity or an appendage, or for the removal of any gland or organ, or part thereof, of the human body; nor shall such license permit the holder thereof to administer drugs, except narcotics, anesthetics, antiseptics, serums, vaccines and antitoxins," and (3) to omit that portion of the present law which prohibits osteopathic licentiates from administering drugs or performing surgery with the use of instruments. A. 996 and S. 1270 propose to prohibit hospitals, supported wholly or partly by public revenue, from collecting any fee for medical services rendered while operating public clinics. A. 1165 proposes to authorize the state commissioner of health to establish in every county one or more cancer clinics. A. 1191 and S. 1273 propose to prohibit experiments on living dogs. A. 1217 proposes to create a board of hairdressers and cosmetologists and to regulate the practice of hairdressing and cosmetology. A. 1477 proposes to accord liens to charitable or governmental hospitals, treating persons injured in accidents, on any judgments or settlements obtained by the injured persons, by reason of such injuries.

New York City

Course for Psychiatric Social Workers.—The New York State Department of Mental Hygiene is conducting an institute for the social workers of the state institutions under its direction, at the New York State Psychiatric Institute and Hospital, February 15 to March 25. Among other lecturers taking part in the course, Dr. Howard W. Potter will conduct a course in child guidance, and Dr. Leland E. Hinsie a course in psychiatry.

Academy Afternoon Lectures.—Coming lectures in the afternoon series at the Academy of Medicine are as follows:

March 11, "Consecutive Clinical and Pathological Events in Cancer," Dr. Harrison S. Martland, Newark, N. J.
March 18, "Practical Points in Surgical Diagnosis," Dr. Frederic W. Bancroft.
April 1, "Chronic Colitis," Dr. Walter A. Bastedo.
April 8, "Ultraviolet Therapy," Dr. Edgar Mayer, Saranac Lake.
April 15, "The Influenzal Cold," Dr. William R. Williams.
April 22, "A Discussion of the Prostatic Problem," Dr. William E. Lower, Cleveland.

Dr. Nathan Rosenthal gave the lecture, March 4, on "Diseases of the Blood," with special reference to treatment.

Child Guidance Bureau to Open Clinic.—The new Bureau of Child Guidance of the Board of Education recently announced that a clinic for the treatment of cases of maladjustment is to be opened at the school at 228 East Fifty-Seventh Street under the direction of Leon W. Goldrich, Ph.D., director of the bureau. In its first experimental year the clinic will concentrate on the district from Forty-Fourth to Eighty-Seventh Street between Fifth Avenue and the East River. The work of the bureau has been organized into three divisions: the educational division, which will concern itself with parent education; the "liaison" division, consisting of representatives of city schools to serve as a link between the bureau and the schools, and a third division, to maintain relations with social agencies.

Graduate Course in Physical Therapy.—A six weeks' course in physical therapy for qualified graduates in medicine will be given at Columbia University College of Physicians and Surgeons, beginning March 15. The course will be limited to twelve and will not be given unless eight apply. It is divided into two weeks of lectures and demonstrations, which will be given at the College of Physicians and Surgeons, two weeks of clinical demonstrations, and two weeks of supervised clinical practice in several hospitals in the city. Instructors will be Drs. Norman E. Titus, William Bierman, Charles R. Brooke, Harold M. Herring, Cassius Lopez-de Victoria, Madge C. L. McGuinness, Robert Muller, Randolph Raynolds and William B. Snow, Jr. The fee for the course is $150.

Demonstrations in Physical Therapy.—The Medical Society of the State of New York, through its committee on public health and medical education, sponsored a series of conferences and demonstrations on physical therapy in traumatic conditions for members of medical societies of New York and Bronx counties at the New York Academy of Medicine during February. Physicians in charge were Drs. William V. Healey, "Indications and Contraindications"; Heinrich F. Wolf, "Uses and Technic of Superficial Health Measures"; William Bierman, "Uses and Technic of Diathermy"; Kristian G. Hansson, "Uses and Technic of Massage and Therapeutics"; Richard Kovacs, "Electrodiagnosis: Galvanic and Low Frequency Currents," and Herman L. Reis, "The Compensation Viewpoint."

Society News.—Dr. Joseph H. Globus addressed the Medical Society of the County of Queens, February 23, on "Brain Tumors: Anatomy, Diagnosis and Management." The society has recently authorized the formation of a section on internal medicine and pathology.——Among other features a symposium on the heart was given at the meeting of the International and Spanish-Speaking Association of Physicians, Dentists and Pharmacists, February 19, by Drs. Russell L. Cecil, Harold E. B. Pardee and Carl P. Sherwin.

Physicians' Art Exhibit.—Two hundred and eighty-one exhibits of paintings, sculpture, prints and objects of art created by seventy-three American physicians make up the annual show of the New York Physicians Art Club, now in progress at the New York Academy of Medicine. According to the New York *Times*, the work is conservative and there is a preponderance of outdoor subjects, which indicates that for the physician art is largely a vacation activity. Thirteen contributors from outside New York are represented, including two from California. Dr. Louis C. Schroeder is secretary of the club.

NORTH DAKOTA

Society News.—At a meeting of the Cass County Medical Society, Fargo, January 25, speakers were the following physicians from Minneapolis: Drs. Chester A. Stewart, "Resolving Parenchymal Tuberculosis of First Infection in Infancy"; Solon Marx White, "Groundwork for Medical Service"; James M. Hayes, "Treatment of Acute Empyema of the Gallbladder"; Walter A. Fansler, "Cancer of the Rectum," and Dr. Edward L. Tuohy, Duluth, Minn., "Chronic Nontuberculous Lung Lesions."——Dr. Avery D. Prangen, Rochester, Minn., was the guest speaker at the midwinter meeting of the North Dakota Academy of Ophthalmology and Oto-Laryngology, Fargo, February 13; his subjects were early management of strabismus, operative treatment of strabismus, and problems and procedures in refraction.

OREGON

Meeting of Medical Alumni.—The annual meeting of the Alumni Association of the University of Oregon Medical School will be held at the university, March 7-9. Disorders of the heart will be the principal topic for discussion, with Dr. William C. Munly, San Francisco, as the guest speaker. Eighteen clinics covering general and special phases of medicine and surgery are scheduled.

PENNSYLVANIA

Society News.—Dr. Hugh R. Robertson, Warren, discussed the history of anatomy in his address as retiring president of the Warren County Medical Society, January 18.——Dr. George Harlan Wells, Philadelphia, addressed the York County Medical Society, January 16, on treatment of pneumonia. At the society's annual banquet, January 7, Drs. Spencer M. Free, DuBois, and Wilmer Krusen, Lansdowne, spoke on "Sentiment in a Doctor's Life" and "The Doctor in Literature," respectively.——Dr. John R. Caulk, St. Louis, will address the Pittsburgh Urological Association, March 14, on "Use of the Cautery Punch in Relief of Urinary Obstruction Caused by Carcinoma of the Prostate."——At a meeting of the Pittsburgh Academy of Medicine, February 23, Dr. Charles C. Guthrie presented a "Summary of Results of Twenty-Years' Experimental Study of the Heart," and Dr. Robert C. Grauer, a paper on "Practical Aspects of Calcium Metabolism in the Light of Recent Experimental Study."——Drs. Elmer H. Funk, Philadelphia, and Samuel B. English, Glen Gardner, N. J., were the guest speakers at the forty-second winter meeting of the Lehigh Valley Medical Association in Allentown, January 28. Dr. Funk spoke on diseases of the kidneys and Dr. English on compression of the lungs.——Dr. John A. McGlinn, Philadelphia, addressed the Berks County Medical Society, February 9, on "Control of Uterine Bleeding."——Dr. Donald Guthrie, Sayre, addressed the Erie County Medical Society, Erie, February 2, on early diagnosis and treatment of acute intestinal obstruction.

Philadelphia

Society News.—Dr. William H. Kraemer, Wilmington, Del., was elected president of the Alumni Association of Jefferson Medical College at the thirty-sixth annual meeting, February 18, at the college.——Dr. Calvin M. Smyth, Jr., delivered the postgraduate seminar of the Philadelphia County Medical Society, February 26, speaking on traumatic surgery.——At a meeting of the Philadelphia Neurological Society, February 26, speakers were Drs. Melbourne J. Cooper, "Tumors of the Gasserian Ganglion"; Ross H. Thompson, "Focal Enlargement of the Temporal Bone as a Sign of Brain Tumor"; George Wilson and Murray M. Friedman, "Hereditary Cerebellar Ataxia."

Personal.—Dr. Charles E. Bricker, said to be the oldest city police surgeon in point of service, has resigned, effective, March 1, because of ill health. He was appointed in 1884.——

Dr. Robert A. Schless was appointed acting chief of the Bureau of Charities and Correction, February 11, by Clinton R. Woodruff of the department of public welfare.

Da Costa Lecture.—The second annual lecture under the John Chalmers Da Costa Foundation, established in 1930, will be delivered by Dr. Thomas A. Shallow, professor of surgery, Jefferson Medical College, before the Philadelphia County Medical Society, March 9, on "Diverticulum of the Esophagus." Dr. Da Costa delivered the lecture in 1931, reviewing his forty years' work in surgery (The Journal, March 14, 1931, p. 871).

SOUTH CAROLINA

Personal.—Dr. D. Lesesne Smith, Spartanburg, has been appointed a member of the state board of health to succeed the late Dr. Davis Furman, it is reported.

Bills Introduced.—S. 1286, to amend the pharmacy practice act, proposes to permit any licensed physician to obtain, without examination, a license to practice pharmacy. H. 1520 proposes to create a commission of charitable institutions to assume and exercise all powers, duties and functions now exercised by the superintendents of the state hospital, the state training school and the John de La Howe industrial school. H. 1521 proposes to abolish the board of medical examiners and the board of pharmaceutical examiners and to vest their respective powers, duties and functions in the state medical college.

VIRGINIA

Third McGuire Lecture.—Dr. James S. McLester, Birmingham, Ala., delivered the third annual Stuart McGuire Lecture of the Medical College of Virginia, in Richmond, March 4, on "Nutrition in Its Newer Aspects." The McGuire Lecture was established in recognition of the service of Dr. McGuire to the college, to medical education and to surgery.

Bills Introduced.—H. 181 proposes that the health commissioner (1) shall be the executive officer of the state board of health; (2) shall be a physician, a graduate of a medical college recognized by the Virginia State Board of Medical Examiners, and (3) shall be skilled and experienced in the administration of public health duties and versed in sanitary science. H. 196 proposes to accord liens to hospitals treating persons injured in accidents, on any judgments or settlements obtained by the injured persons by reason of their injuries. H. 222 proposes to repeal that section of the law regulating the sale of "hypnotic drugs" which requires that such drugs shall not be sold or given away except on the written prescription of a licensed physician, dentist or veterinarian. S. 270, to amend the medical practice act, proposes (1) that in proceedings against a person for practicing medicine or any branch thereof, without a license, the burden of proof shall be on the defendant to establish his right to practice; (2) to authorize the board of medical examiners, to revoke or suspend a license of a person who is grossly ignorant or careless in his practice, and (3) to state in detail the procedure to be followed in revoking a license.

GENERAL

Change in Date of Meeting.—The American Association of Pathologists and Bacteriologists will meet in Philadelphia, April 28-29, instead of March 24-25, as previously announced. Dr. Howard T. Karsner, 2085 Adelbert Road, Cleveland, Ohio, is the secretary.

Memorial to War Dietitians.—A memorial to the dietitians who served in the World War, given by the American Dietetic Association, was unveiled in the American Red Cross Building, February 6. Among the speakers was Major-Gen. Robert U. Patterson, surgeon general of the U. S. Army, on "The Future of the Dietitian."

Midwinter Clinic.—The American Association of Obstetricians, Gynecologists and Abdominal Surgeons will hold its midwinter clinic in Philadelphia, March 7. The group will visit in turn for surgical, gynecologic and obstetric clinics the following hospitals: Joseph Price Memorial, Temple University, Stetson and Jefferson, including Curtis Clinic. After a dinner at the Union League the guests will hear addresses by Drs. James W. Kennedy and Barton Cooke Hirst, on "Joseph Price, the Man, Philanthropist and Surgeon" and "Development of Obstetrics and Gynecology in Philadelphia," respectively, and will see a motion picture on the "Ectopic Heart," presented by Dr. I. Charles Lintgen.

Pacific Coast Obstetrical and Gynecological Society.—At a recent meeting in San Francisco, the Pacific Coast Obstetrical and Gynecological Society was organized. Dr. Frank W. Lynch, San Francisco, was elected president, and Dr. Albert L. Mathieu, Portland, Ore., was made president-elect. Dr. Clarence A. DePuy, Oakland, was elected secretary. The object of the society will be to organize members of the medical profession who limit their practice to obstetrics and gynecology for the promotion of the highest ethics of the specialties. The membership is composed of active, senior and honorary members. The active membership is limited to fifty. The next meeting of the society will be held in Los Angeles in November.

Society News.—The American Psychiatric Association will hold its annual meeting in Philadelphia, May 30-June 3.——The American Urological Association will meet, May 30-June 2, in Toronto.——Dr. Ira Solomon Wile, New York, was elected president of the American Orthopsychiatric Association at its annual meeting in Baltimore, February 18-20; Dr. Frederick H. Allen, Philadelphia, was elected vice president, and Dr. George S. Stevenson, New York, reelected secretary.——The American Association of School Physicians will hold its fifth annual meeting in Washington, D. C., October 21-22, preceding the meeting of the American Public Health Association, October 24-27.——Dr. Clarence A. Shore, Raleigh, was elected president of the Tri-State Medical Association of the Carolinas and Virginia, at the annual meeting in Raleigh, N. C., February 15-17. Among speakers at the meeting were Drs. John Shelton Horsley, Richmond, on "Double Harelip"; Wingate M. Johnson, Winston-Salem, N. C., "Influence of General Infections on Local Lesions"; Charles S. White, Washington, D. C., "Reidel's Thyroiditis," and Tom Douglas Spies, Cleveland, "Pellagra a Disease of Unknown Etiology—Response to an Unorthodox Diet." Dr. Henry Mason Smith, Tampa, Fla., made an evening address, February 15, on "The Cerebral Mechanism of Sleep and Some of Its Disorders."

Medical Bills in Congress.—*Changes in Status:* S. 100 has passed the Senate, authorizing any institution heretofore incorporated under the laws of the District of Columbia, operating exclusively in a foreign country, to use the words "American," "Federal," and similar words in its title. S. 695 has been favorably reported to the Senate, with amendment (Senate Report No. 295). The bill originally proposed among others things to authorize an appropriation for $20,877,000 for additional hospitals and domiciliary and outpatient facilities. The amendments offered by the committee strike from the bill everything relating to such proposed construction and only provide for a reduction in payments to veterans under the Disabled Emergency Officers Retirement Act while they are being maintained in institutions by the Veterans' Administration. S. 894 has passed the Senate, directing the retirement of acting assistant surgeons of the United States Navy at the age of 64 years. S. 3110 has passed the Senate, with an amendment, authorizing the Secretary of the Interior to arrange with the states for the education, medical attention and relief of Indians. H. R. 9699, the Treasury and Post Office Departments appropriation bill, has been reported favorably to the House. It carries an appropriation of $11,421,413 for the United States Public Health Service, including the sum of $300,000 for special studies of, and demonstration work in, rural sanitation. The bill also proposes an appropriation of $1,625,000 for the Bureau of Narcotics. *Bills Introduced:* S. 3759, by Senator Norbeck, South Dakota, to construct and equip a hospital for Indians at Wagner, S. D. S. 3766, by Senator Thomas, Oklahoma, to provide that any ex-service person shown to have had a tuberculous disease of a compensable degree for a period of five or more consecutive years, and whose disability on account of such disease during such period has been rated as total and temporary, shall be held to be totally and permanently disabled for all purposes under the World War Veterans' Act. S. 3781, by Senator Costigan, Colorado, to authorize an appropriation of $100,000 to recondition the buildings at the veterans' hospital, Fort Lyon, Colorado. S. 3800, by Senator Copeland, New York, to provide for federal cooperation with the several states in the physical restoration, education, vocational guidance and vocational education of "any person below the age of twenty-one years who by reason of physical defects or infirmities, whether congenital or acquired by accident, injury, or disease, are or may be expected to be totally or partially incapacitated for participation in the educational and vocational activities expected of normal persons." S. 3818, by Senator Copeland, New York, to provide for the vocational rehabilitation of persons disabled in industry or otherwise. S. 3819, by Senator Copeland, New York, granting permits for the importation or manufacture for nonbeverage purposes of spirituous liquors of a particular kind or quality where the supply in the United States is insufficient to meet the current needs therefor. H. Res. 161, by Representative Rayburn, Texas, to provide a special rule for the consideration of H. R. 7525, the Bankhead rural health, and maternity and infancy hygiene bill. This resolution is before the House Committee on Rules. H. R. 9260, by Representative Crowe, Indiana, to provide additional compensation for World War veterans for the loss of use of an eye in active service in line of duty. H. R. 9307, by Representative James, Michigan, to repeal the Emergency Officers' Retirement Act.

Deaths in Other Countries

Geheimrat Max von Frey, Ordinarius at the Physiological Institute, University of Würzburg, Bavaria, Germany, known for his research in the field of tactile, pain and caloric sensibility, died, January 25, in his eightieth year.

Government Services

U. S. Public Health Service

The following physicians have recently entered the public health service and have been assigned to active duty as follows: Asst. Surgs. David C. Elliott assigned to the marine hospital at Louisville; Benton Oliver Lewis, assigned to duty at Roma, Texas; Charles T. Meacham, Jr., Kinston, N. C., assigned to the marine hospital, Stapleton, N. Y., and Henry L. Wollenweber, Los Angeles, assigned to the marine hospital at San Francisco; Asst. Surg. Ralph Gregg has been promoted and commissioned as passed assistant surgeon, effective Dec. 28, 1931; P. A. Surg. Langdon R. White, relieved at Helena, Mont., and assigned at Albuquerque, N. M.; P. A. Surg. Elmer A. Carberry, relieved at San Francisco, and assigned at Manila, P. I.; P. A. Surg. George G. Holdt, relieved at Honolulu, Hawaii, and assigned at marine hospital, San Francisco; Surg. Henry A. Rasmussen, relieved at Cebu, P. I., and assigned at marine hospital, San Francisco.

Change of Station in the Navy

Lieut. Warren G. Wieand from navy hospital, Parris Island, S. C., to second brigade, U. S. Marines, Nicaragua; Lieut. Comdr. Oscar Davis, from navy hospital, Pensacola, Fla., to first brigade, U. S. Marines, Port au Prince, Haiti; Lieut. Comdr. Francis E. Locy from first brigade, U. S. Marines, Haiti, to navy hospital, League Island, Philadelphia; Lieut. Comdr. Leon W. McGrath from first brigade, U. S. Marines, Haiti, to navy hospital, Annapolis, Md.; Lieut. Comdr. John T. Stringer from first brigade, U. S. Marines, Haiti, to navy academy, Annapolis; Lieut. Edward P. Kunkel from navy station, Guam, to Navy Medical School, Washington, D. C.; Lieut. Edward T. Knowles from navy hospital, Mare Island, California, to navy station, Guam; Lieut. Comdr. Russell I. Craig from navy yard, New York, to Asiatic Station; Lieut. Bruce M. Summers, from navy training station, Newport, R. I., to Asiatic Station; Lieut. Burr Dalton, from navy hospital, Newport, to Asiatic Station; Lieut. Freeman C. Harris, from navy hospital, New York, to second brigade, U. S. Marines, Nicaragua; Lieut. Comdr. Elmer F. Lowry, from second brigade, U. S. Marines, Nicaragua, to treatment, Norfolk Navy Hospital, Portsmouth, Va.; Comdr. Gordon D. Hale, from Guardia Nacional Managua, Nicaragua, to navy hospital, Mare Island, Calif.: Comdr. John F. Riordan, from Norfolk Navy Hospital, Portsmouth, Va., to navy hospital, Pearl Harbor, T. H.

The Government Needs Physicians

Examinations are announced by the U. S. Civil Service Commission for the position of senior medical officer, medical officer and associate medical officer (cancer diagnosis and treatment). Applications must be on file with the U. S. Civil Service Commission at Washington, D. C., not later than March 22. Examinations are to fill vacancies in the veterans' administration throughout the United States. The entrance salaries range from $3,200 to $4,600 a year, less $570 a year for quarters, laundry and full subsistence when furnished. Competitors will not be required to report for examination at any place but will be rated on their education, training and experience. Applicants must have been graduated with a degree of doctor of medicine from a medical school of class A standing, senior medical officers or medical officers not more than twenty years and associate medical officers not more than three years prior to March 22, 1932. In addition, certain specified experience is also required. Further information may be obtained from the secretary of the U. S. Civil Service Board of Examiners at the postoffice or customhouse in any city, or from the U. S. Civil Service Commission, Washington, D. C.

Foreign Letters

LONDON

(From Our Regular Correspondent)

Jan. 30, 1932.

Malformations of the Body from a New Point of View

In his lectures at the Royal College of Surgeons, Sir Arthur Keith said that fifty years ago Sir John Bland Sutton wrote a book to prove that in making its great evolutionary advances nature used methods akin to those of disease. An illustration was to be seen in the human body during the second and third months of development. Hernia was then produced outside the abdominal cavity and within the umbilical sac, where the greater part of the intestine underwent differentiation and growth. At the same time, preparations were being carried forward within the abdomen for their final fixation there. It was interesting to compare the modern operation for the radical cure of hernia with that which had been discovered by nature. At the end of the third month of development, the hernia at the umbilicus was cured automatically in a few days; the intestine was drawn back into the abdomen and the opening closed. Prof. J. E. S. Frazer has shown how this takes place. First, the walls of the abdomen expand by growth, so that room is made within for the intestine. Secondly, the mesenteries which attach the intestine to the posterior abdominal wall shorten and widen their attachments and draw in the intestine in a fixed and orderly manner. Thus the hernia, which has served a developmental purpose, is cured. But this process fails in 1 child in 3,000, who is born with an umbilical hernia.

How did hernia at the umbilicus become a normal process in the development of the higher animals? It began when a part of the intestine had to undergo a premature development to contain a store of yolk for the developing fish or frog until it could fend for itself. The developing bowel of the dogfish grows over, envelops and encloses its stock of yolk. At first the fish swims about with the yolk sac suspended from its body, being born with a congenital umbilical hernia, the covering of which is supplied by the body wall. As the yolk sac empties, the hernia is reduced, leaving no scar. When land-living, air-breathing vertebrates were evolved, the skin covering the yolk sac became more important than the sac itself. By precocious development and enormous expansion of the covering of the yolk sac, a hood was formed. This grew over and enclosed the developing embryo in a double envelop, the inner of which contained water. Thus the delicate tissues of the embryo were submerged in and supported by water, as are the eggs of the fish or frog, which can develop only in a fluid medium. The outer envelop serves as a lung. The umbilicus is the scar left at the point of detachment. Part of the body wall has been sacrificed for the development of the individual, and the umbilical scar is the token of this. In the higher mammals, including man, matters are carried a stage further. In the earlier stages of development, all efforts are expended on an extensive formation of that part of the body wall which in lower vertebrates (reptiles and birds) forms the envelops of the embryo. Development within a rigid shell and development within a living contractile uterus require different methods. The developing human ovum has to burrow into the living membrane of the uterus and in this position throw out its envelop—amnion and chorion. During this early period, from the eighth to the fourteenth day, the embryo itself remains in abeyance; all efforts are spent on the development of the coverings and the placenta, which have been evolved out of that part of the body wall which covers the yolk sac of fish and frog. The epithelial covering of the skin becomes the wildly growing devouring trophoblast. Part of the body wall becomes drawn out to form the umbilical cord. It is therefore not surprising that at a certain stage of development the cord contains coils of intestine, nor, when the elaborate processes for the withdrawal of the intestine from the sac are considered, that children should occasionally be born with a developmental hernia unreduced.

Sphalinger Discloses His Secrets

For many years, Sphalinger's treatment of tuberculosis has been brought before the British public. Extravagant claims were made for it, principally in the lay press, where campaigns describing him as a scientist who had spent his fortune in investigation for the benefit of humanity have been carried on from time to time. In 1922 the British Red Cross voted a large sum to enable him to produce his remedies, and the ministry of health offered facilities for their trial under scientific supervision. But while appealing for funds, Sphalinger resolutely refused to disclose the method of production of his vaccine, declaring that this would lead to improper exploitation. Hence the medical profession, with a few exceptions, ignored him. At last he has changed his tactics, and at a meeting held in a private house in London attended by some persons of social but not of medical importance (many of whom had given him financial support) he announced that his vaccine for immunization of cattle is prepared by culture of tubercle bacilli obtained from the slaughterhouse. A bovine body fluid (defibrinated serum, organ or tissue extract) is coagulated in an incubator at 65 C. When cold, there is spread on the coagulated surface a small quantity of normal (nonheated) bovine body fluid. These mediums are inoculated with native bovine bacilli (unaltered by passages on artificial mediums or through another animal species) and are incubated in the dark at from 38.5 to 39 C. As soon as the culture has sufficiently grown it is reinoculated on specific normal (unheated) bovine mediums, preferably liquid, consisting of defibrinated blood, serum, organ extract or tissue extract. These cultures are again incubated in the dark at the same temperature. The bacilli from them are collected and made into an emulsion, in the absence of oxygen, with distilled water or physiologic solution of sodium chloride. The emulsion is kept cool and in the dark until all the bacilli have died a natural death. It is necessary to keep a vaccine a year or more before it can be used. It is then harmless, though effective for immunization. For man the vaccine comprises a mixture of three types of vaccine: (1) the bovine vaccine described, (2) a vaccine made from bovine bacilli grown in the dark at 37.5 C. on human defibrinated blood, serum, ascitic or pleural fluids, and (3) a vaccine made from human bacilli grown on the last mentioned mediums. The human bacilli should be isolated from a human lesion without animal passage to avoid adaptation to another species. The human and bovine culture mediums must come from tuberculosis-free bodies. Sphalinger says that, while there are fifteen kinds of tuberculin on the market, his is the only one that confers immunity.

Poisoning by Arsenic in Wall Paper Rendered Gaseous by Molds

An inquest was held on a girl, aged 7 years, who lived in the forest of Dean. The county analyst found 2.65 mg. of arsenic in her body. In the sitting room of her house he discovered that arsenic was being given off in gaseous form from the wall paper, which was affected by mold. In samples of the paper from the dry parts of the wall he found 8.3 parts of arsenious oxide per million, but where the mold grew there were only 2.3 parts; in the plaster there were 91 parts. The spores of the mold attached themselves to the damp paper, grew vigorously, and generated a gaseous form of arsenic. He also found traces of arsenic in the systems of other members of the family. Prof. H. A. Scholberg, honorary pathologist to the Cardiff Infirmary, said that what he considered had happened was that the flour paste used for putting on the paper provided a medium for the growth of the mold, which then liberated the arsenic. The jury returned a verdict of death from dysentery, with arsenical poisoning as a contributory cause.

Crystalline Vitamin D

At a meeting of the Royal Society, F. A. Askew, R. B. Bourdillon, H. M. Bruce, R. K. Callow, J. St. L. Philpot and T. A. Webster reported that further purification of vitamin D had been achieved by esterification of the distillate formerly described as "calciferol." The purified product has an activity twice as great as any previously recorded and appears to be identical with vitamin D_2 of Linsert and Windhaus. It produces toxic effects when given in excessive doses. A simplified process was described for preparing the pure product from the irradiation products of ergosterol without distillation.

Annual Assembly of the Confederation of French Medical Syndicates

The annual assembly of the confederation of the French medical syndicates is a convention of the delegates chosen by the medical syndicates of the various departments of France and is devoted solely to the consideration of professional problems. This last assembly was characterized by considerable agitation and gave rise to heated discussions on problems that are disturbing the minds of French practitioners. The most important question considered was the law pertaining to social insurance. By their concerted action and by threatening to refuse to cooperate with the government in the application of this law, the syndicates have succeeded in creating for themselves a tolerable situation, since persons holding such social insurance are compelled to pay their physician immediately themselves and are then reimbursed by the departmental sick benefit funds for a certain proportion of the sum expended. In this manner the physician is always certain of being paid the fee that he asks, and the patient is absolutely free to choose the physician that he prefers. But this situation is threatened in various ways; for the law is based on an unfortunate conception that is costly for the insured, for the employers and for the state, and the government is seeking to take away from the physicians, in a roundabout way, a part of the guarantees that it was obliged to concede to them at the time the law was voted on. Thus, a new bill has been proposed that provides for the administration of the sick benefit funds by the old mutual aid societies, which have not ceased to exist, in spite of the fact that they fulfil the same purposes as the law, and which continue to exert a wide influence, from the political point of view, on the members of parliament. The confederation of the medical syndicates has decided to oppose this bill by every available means; for these societies apply a much lower fee schedule than the regular fee schedule of the physicians. Furthermore, the societies pay the physician according to the societies' schedule; the physicians do not collect from the patient. If the pending bill is passed, all the advantages that the syndicates secured for the medical profession at the time the law was voted on will be lost. The confederation protested likewise against a proposed bill that would lower the fee schedule agreed on for occupational accidents, on the ground that, since this agreement was entered into, there has been a decline in the cost of living. The statement is inaccurate, and, furthermore, there has been considerable increase in the professional taxes imposed on physicians. Long discussions were carried on with regard to the creation of centers of diagnosis, a proposal originating with the administration of the sick benefit funds. Many of the representatives of the medical syndicates were systematically opposed to the idea, because they feared it would result in the diminution of fees for the physicians who specialize in radiologic and biologic examinations. The general secretary of the confederation, Dr. Cibrié, who was attacked at first for the support he gave the project, succeeded, by force of eloquence, in convincing the assembly that the syndicates would find it to their advantage to take the lead in the creation of such centers, provided the physicians serving in the centers would agree not to accept private patients outside the centers, would confine themselves to patients sent to them by the practitioners, and would accept the fee schedule adopted by the syndicates. This would be the best means of preventing the health insurance societies from establishing such centers themselves, which would entail a much heavier financial loss for the members of the syndicates.

A Model Radiologic Service in Paris

At the Hôpital St. Louis, a large radiologic service has been created that embodies all modern improvements imaginable. The minister of public health attended in person the opening of the new service. The institute was erected through the initiative of Dr. Belot, director of the service, who supervised himself all the details of the construction. A thick wall sheathed with sheets of lead insulates completely the roentgen apparatus from the booth occupied by the patients and the operators. The operators control the apparatus from a distance. The floor is entirely insulated by a thick layer of rubber. In addition to numerous dressing rooms for the patients, there are three rooms for radiologic diagnosis. The physician dictates his observations to secretaries, seated in an adjoining room, by means of a microphone and loud-speaker. The roentgenologist is enclosed in a special booth that assures him absolute protection. A powerful generator enables the operator to make roentgenograms of the lung at the rate of one every 2/100 second. Dummy lifts are used to transfer the plates at once to the laboratories on the ground floor, where they are immediately developed and then placed in an electric drier. The radiotherapeutic service comprises ten rooms. The patients are enclosed in a booth and the nurses control the apparatus from without, while they supervise the patient through a small window in the wall. There are two sets of equipment for superficial roentgenotherapy, an apparatus for moderately penetrative roentgenotherapy, and three sets of equipment for high voltage roentgenotherapy with 250 kilowatts. The generators are coils with a constant tension of 30 milliamperes. The Coolidge tubes, standard type, are enclosed in opaque containers. In other rooms are the various types of apparatus for physical therapy: mercury lamps, diathermic devices, arc lamps, and the like; the filing cabinets; in addition, there are assembly and recreation rooms. Foreign physicians who visited the institute at the time of holding of the International Radiologic Congress stated that nowhere else is there an institute so complete and so modern. From the standpoint of capacity, 10,000 patients a year can be given diagnostic examinations and 30,000 patients can receive widely divergent forms of treatment each year.

Distribution of a Large Government Appropriation

Mr. Camille Blaisot, minister of public health, has decided on the manner of distributing the sum of 385,000,000 francs, which has been placed by parliament at the disposal of his department as a portion of the appropriations made for the improvement of the national equipment for the promotion of public health. The dominant idea governing the distribution was the desire to use the appropriated sums chiefly for undertakings that would necessitate the employment of a large amount of man power. The distribution as affecting hospital centers was influenced, in part, by a consideration of the needs and the local possibilities for absorption of the appropriated sums during 1932. For the hospital units the subsidies allowed amount to 180,000,000 francs. Subsidies amounting to 30,000,000 francs were accorded to societies that support the crusade against child mortality. The sum of 5,000,000 francs was granted to the vacation camps and the camps located adjoining hot springs. As regards the organizations carrying on the crusade against the social diseases, it will be observed that the anticancer centers are to receive 27,000,000 francs; the societies devoted to the eradication of venereal disease, 16,000,000; the sanatoriums, 33,000,000; the preventoriums, 21,250,000; the antituberculosis dispensaries, 2,960,000, and the schools for the training of nurses, 15,590,000. Certain societies that have an appeal from the scientific or social point of view are to receive efficient financial aid; such, for example, as the Institut du radium of the Curie Foundation, 12,500,000 francs; the anticancer center at Villejuif, 12,500,000; the Renaissance sanitaire (hospitals of the mutual aid societies), 11,500,000; the Ecole de puériculture de la Faculté de médecine de Paris, 8,091,000; the Foch Foundation, 4,000,000, and the society for the mutual protection of railway employees (Etrembrières, Haute-Savoie), 2,000,000.

Budget of the Assistance Publique in Paris

The municipal council of the city of Paris has finally accepted the budget of the Assistance publique for the year 1932. The director of the service, Mr. Louis Mourier, had been compelled to make a demand that the Assistance publique be reimbursed by the department of social insurance for the expenditures occasioned by the hospitalization of its insured members. The sum set aside for the purpose was 62,000,000 francs; but, during the year, this allowance was reduced to 22,000,000 francs, of which only 13,000,000 francs has been turned over. Mr. Mourier holds that, in order to regulate definitely the relations between the Assistance publique and the department of social insurance, the law should be modified and a lump sum agreed on, which, after careful calculations, he placed at 54,600,000 francs. Such a system would obviate a great deal of paper work, which would constitute the best argument in favor of the change in the law. He will bring the matter before the government authorities at a later date. The council then agreed on the subsidy that the city was to allow the Assistance publique, which was fixed at 321,470,617 francs, 3,470,617 of which was for the bureaus of public charity. It approved likewise the various proposals of the chairman of the budgetary committee concerning the erection of hospitals, and repairs and improvements in the existing hospitals.

BERLIN

Jan. 18, 1932.

Automobile Accidents Due to Drunkenness

Both the Prussian ministry of commerce and industry and the ministry of the interior have drawn attention to the fact that numerous traffic accidents occurring in recent months have been due to intoxicated drivers. It is emphasized that a small quantity of alcoholic beverages is sufficient to reduce materially the steadiness, the keenness of observation and the reaction time of the driver. The driver of an automotive vehicle—whether public or private—who, in compliance with the ordinance affecting the traffic of automotive vehicles, is "under strict obligations to exercise proper care in the driving and management of his vehicle," violates the law if he drives his car after he observes that he is under the influence of alcohol. In such an event he is under obligations under all circumstances to desist from driving his car. In the future, every driver of an automotive vehicle who causes an accident as a result of the ingestion of alcoholic beverages will without exception be deprived of his license. According to a decision of the supreme court, no consideration should be given to the financial status of the driver or to the contention that the financial position of the driver would be jeopardized if his license should be canceled. In the schools that give instruction in automobile driving, special emphasis should be placed on the consequences of such violations.

Eugenics as a Subject for Medical Students

The state council of Prussia will in the near future consider a proposal that the study of eugenics and of the theory of heredity be made obligatory for physicians, teachers and theologians and a subject for examination for physicians. The proposed legislation provides also that the pupils of the upper classes in the grammar schools, high schools, trade schools and continuation schools be given instruction concerning the essential significance of eugenics and the theory of heredity. Furthermore, an exchange of eugenic health certificates before being engaged to marry, and the widest possible spread of knowledge in these fields to the whole *reich* are demanded. A pamphlet showing the reasons for such legislation, prepared by Dr. Struve, refers particularly to the research of Prof. Dr. Muckermann and of Dr. v. Verschuer of the Berlin Kaiser-Wilhelm-Institut and gives a picture of the danger associated with the neglect of eugenic ideas as affecting the future of the people.

Hockey Injuries

The public does not usually have clear ideas in regard to the frequency of injuries resulting from participation in sport. It will doubtless occasion surprise that statistics covering 2,152 hockey games, in which 23,672 players participated, show that only 0.33 per cent of the players suffered injuries. This result was reached by Privatdozent Dr. Arnold of the department of athletics at the University of Leipzig. The injuries were distributed as follows: men players, 0.35 per cent; male juveniles, 0.25 per cent, and women and girls, 0.35 per cent. The low percentage in male juveniles is explained by the facts that they do not enter into the game quite so vigorously as do adults, and that their greater elasticity in case of falls and collisions reduces the danger. If one considers only the typical hockey injuries, those that are caused by hockey sticks and balls, and excludes those that occur also in connection with other sports, the proportion of hockey accidents is reduced to 0.19 per cent. Arnold observed twice as many injuries from hockey sticks as from the puck. Among women players, however, injuries resulting from the driven object were more frequent. Injuries from hockey sticks concern chiefly the head and only secondarily the lower extremities — less frequently the upper extremities and the trunk. Injuries inflicted by the driven object have a similar distribution. Indirect injuries, on the other hand, concern more frequently the limbs, and more rarely the head and trunk. Almost two thirds of the injuries in the narrower sense are injuries of the soft parts. Injuries of the bones and joints follow but are much less frequent. Fractures are, however, rare. Commensurate with the predominance of the stick and ball injuries, persons so injured recover rapidly. However, after indirect hockey injuries, considerable time usually elapses before injured persons can again take up the game.

The Storing of Roentgen Films

A police ordinance concerning the storing of roentgen films went into effect in Prussia, January 1. The ordinance applies not only to hospitals but to all other institutions for the care of health and the promotion of public welfare: care-taking and consultation centers, policlinics, ambulatoriums, laboratories and the offices and "institutes" of practicing physicians. There is a general prohibition against leaving roentgen films around open for any length of time. They must not be kept permanently in sickrooms, even when wrapped or enclosed in holders. Various regulations that presuppose a far-reaching control are imposed also for unused and for developed films, files and supply houses. In buildings that are permanently occupied by human beings, the storing of supply stocks is permitted only in the top story, and the use of the building for that purpose must be in accordance with the municipal fire regulations, which applies also to store rooms that serve solely as depositories of films. Special regulations must be followed with reference to heating, the installation of electric lights and protection against lightning. Not only the hospitals but also the general practitioners must secure permission to store roentgen films. These safety provisions are not applicable if roentgen safety films are used exclusively or stored by themselves. The safety films bear on the package and on each film the name "DIN-Sicherheitsfilm." This designation can be applied only to a film which, if a piece 20 cm. long and 3.5 cm. wide is held vertically and is lighted with a match at the lower edge, after removal of the flame either ceases to burn or requires sixty seconds for its complete combustion.

The Anatomy of the Child

The "Museum des Kindes" is to be opened, April 1, in the building of the Allgemeine Ortskrankenkasse in Hamburg. For this purpose, the method of the Leipzig anatomist Spalteholz for the making of anatomic preparations transparent has been further developed. The object of the exhibit is to make an exact knowledge of the healthy and the sick child available to every one. The exhibit will comprise 150 preparations that illustrate the normal and pathologic anatomy of the child, showing the development from the third day of embryonic life up to the ninth month inclusive. The original preparations will be finely executed and great importance will be laid on technical accuracy. For example, one will be able to see the stained blood vessels and the internal organs.

POLAND

Polish Conference on Tuberculosis

The fourth Polish Conference on Tuberculosis was held at Zakopane, a climatic resort on the slope of the Tatra Mountains, in September, 1931. The sessions were held under the chairmanship of Dr. Severin Sterling, dean of the Polish phthisiologists, in the sanatorium of the Polish Red Cross Society. Especially interesting were the papers of Drs. Michałowicz and Popowski of Warsaw, and of Skibiński of Zakopane, which dealt with the relation that exists between the allergic manifestations and the resistance of the organism in tuberculosis. Dr. Skibiński expressed the view that pulmonary tuberculosis should be treated by introducing active bacilli into the patient. Children under 2 years of age should be protected against infection, and should be immunized by inoculation before reaching the age of puberty. It is more difficult to contract tuberculosis after puberty, but the infection is then more dangerous. Skibiński considers the installation of isolation services in the sanatoriums as superfluous, for such action tends to increase fear. Supplementary infections are not always harmful; they sometimes develop a greater resistance than the elementary infection and may aid in the treatment of the existing disease.

The conventionists visited the sanatorium for teachers and the hospital, and attended the dedication of a new health center in Zakopane. The following day, Dr. Etienne Rudzki lectured on the classification of tuberculous patients. The diagnosis must not be based solely on the physical examination but must take into account also the bacteriologic, serologic and radiologic tests. It must be discovered whether the tuberculous process is active or stationary. Not until after the establishment of a sure diagnosis should the patient be sent to an institution in keeping with his condition. All patients should be registered in the antituberculosis dispensaries. He advocated the application in Poland of the classification of Sterling, adopted by the first Polish Conference on Tuberculosis, held in 1925. As for the preventive treatment, it is applied to those who have not developed as yet an active process but who come from a milieu contaminated by tuberculosis; also to suspects, and to patients who have passed through a congestion of the lungs or a surgical tuberculosis. The new-born who may have been contaminated by their environment should be subjected to a preventive inoculation and should be kept isolated as long as possible.

Patients affected with active tuberculosis receive clinical treatment at home and in the sanatoriums. When feasible, provision should be made in the dispensaries for pneumothorax treatment. The dispensaries should preserve their character of preventive institutions, after the pattern conceived by Philippe and Calmette. Patients in whom slight toxic symptoms have been discovered can be treated at home or in the dispensary. Patients who, it is thought, will recover their earning capacity within six months are sent to the sanatorium. Patients who present little chance of a complete recovery or a prolonged amelioration are candidates for the retreats, organized after the plan adopted in Norway.

Dr. Dabrowski of Warsaw emphasized the immense importance of the dispensary and approved the proposal to organize dispensaries in the hospitals. His paper was illustrated by a series of interesting slides.

Dr. Fiszer of Zakopane discussed a series of individual cases that required sanatorium treatment and gave some interesting details on present methods of treatment.

On the third and last day, Dr. Zychoń presented a paper on the advantages of an Alpine climate for the treatment of tuberculosis. Drs. Gaston Poix of France, C. Wroczyński, head of the Polish Red Cross Society, and G. Babecki of Warsaw presented papers on the rôle of social insurance in the crusade against tuberculosis. Dr. Wroczyński traced the historical development of the social insurance movement and explained the part played by the health insurance societies (*krankenkassen*) in the fight against tuberculosis. Dr. Poix, who read a paper on "The Rôle of Social Insurance in France in the Crusade Against Tuberculosis," explained the methods chiefly employed in the crusade against tuberculosis and emphasized the predominant rôle of the dispensary, where pneumothorax treatment is generally applied.

Dr. Babecki read a paper on a proposed merger for the social crusade against tuberculosis, in which he explained the work accomplished by the health insurance society in the domain of the crusade against this disease. The federation of the health insurance societies has appealed to the governmental, communal and private organizations to cooperate in the development of preventive measures. The speaker proposed the organization near large urban centers of colonies for the tuberculous which would be provided with sanatoriums for persons gravely ill, for persons suffering mild attacks, and for convalescents. There would be furthermore day sanatoriums and night sanatoriums, and industrial colonies in which convalescents will be given opportunities to earn their living.

After the presentation of papers, these ten resolutions were adopted without a dissenting vote:

1. The fourth Conference on Tuberculosis appeals to the people of Poland, and it urges it not to diminish its contributions in aid of the crusade against the great social scourge tuberculosis, the extension of which is again becoming more threatening, on account of unemployment and the misery that results therefrom.

2. The fourth conference, taking into consideration the economic condition of the country, as a result of which the sanatoriums are almost empty, advises against the erection of luxuriously equipped sanatoriums and of pseudosanatoriums and expresses the view that hospital-sanatoriums with moderate prices should be organized.

3. The fourth conference makes an appeal to all the governmental, communal and social institutions and to the institutions of social insurance to collaborate in the organization of the crusade against tuberculosis in their respective regions under the form of special associations, taking as an example the association for combating tuberculosis organized at Lodz (Poland).

4. The fourth conference considers it advisable that all the institutions that participate in the crusade against tuberculosis contribute funds for the creation of special colonies for the tuberculous where patients of all classes may find the best conditions for treatment and where patients and convalescents may work without injuring their health or endangering their entourage; whereas, if they were transferred to a different environment and were compelled to work under less favorable conditions, their condition would deteriorate, and, at the same time, they would prove a menace to their immediate environment.

5. The fourth conference, since there is in the Alpine region no secondary school possessing the character of a sanatorium, appeals to the government to supply this need, as soon as possible, by carrying out the plan of the minister of public instruction.

6. The fourth conference decides as follows with relation to the accepted designations for therapeutic institutions for the beneficiaries of social aid: (*a*) A sanatorium is an establishment, under professional management, to which are admitted tuberculous patients who require treatment and in whom the treatment can be expected to give marked and durable results. (*b*) A hospital-sanatorium is an establishment, under professional management, destined for the treatment of tuberculosis under any and all aspects susceptible of treatment, not excluding incurable cases. Such an establishment should have a special service termed "observation and diagnostic service."

7. The fourth conference, having in mind the great importance, in the social crusade against tuberculosis, attaching to prophylactic education, as applied to the younger generation, expresses the hope that the school physicians who have recently been temporarily removed from office, by way of retrenchment, may be reinstated as soon as the economic situation permits.

8. The fourth conference confirms the absolute need of enacting for Poland antituberculosis legislation, and appeals to the organizations concerned to elaborate, as soon as possible, the draft of such a regulation.

9. The fourth conference expresses furthermore these views: (*a*) All agencies of a professional character: general practitioners, dispensaries, hospitals and sanatoriums are authorized, and even under obligations, to interest themselves in the fate of patients and to wage constant warfare against tuberculosis. (*b*) The cost of treatment of the tuberculous patient should not be charged to his account alone, but should be borne in part by government, communal and social institutions. (*c*) Zakopane possesses the climatic conditions requisite for the treatment of tuberculosis. (*d*) A sanatorium with moderate prices for the benefit of the middle class should be erected in Zakopane. (*e*) A central institution should be provided in Zakopane for the study of tuberculosis.

10. The fourth conference expresses the conviction that the restoration of the ministry of public health, abolished several years ago, will not only exert a favorable influence on the advancement of health and hygiene in Poland but will likewise effect, in the long run, a great saving for the state treasury.

NETHERLANDS

Accidents Affecting the Circulatory System

The association for the combating of alcoholism has published a brochure on the accidents affecting the circulatory system, occurring in the Netherlands. This brochure may be considered a continuation of that published in 1929. The data collected include the accidents in all the cities, or communes, of more than 20,000 inhabitants (forty-six in all). In these communes there were 28,227 accidents affecting the circulatory system, 262 of which had fatal results, while 1,748 persons received grave, and 5,370 slight, wounds. These figures are higher than those for the previous year.

Accidents Affecting Circulatory System in Seven Communes in 1930

	Total Number of Accidents	Accidents Due to Automobiles	Percentage Due to Automobiles
Amsterdam	7,754	6.275	80.9
Rotterdam	4,830	3.561	73.7
The Hague	3,226	2,695	83.5
Utrecht	1.175	921	78.4
Groningen	1.180	889	75.3
Enschede	602	392	65.1
Leeuwarden	324	218	67.3

Accidents caused by street cars are not included in these figures. In thirty-six communes, 155 accidents affecting the circulatory system were caused by intoxicated drivers.

Postvaccinal Encephalitis

Dr. Josephus Jitta has presented to the permanent committee of the International Bureau of Public Hygiene a communication on postvaccinal encephalitis. In connection with 866,100 vaccinations against smallpox, performed in the Netherlands from 1924 to 1931, there were 186 cases of postvaccinal encephalitis, or 1 case to 4,656 vaccinations, on an average. It should be noted that since May, 1930, no case has occurred, although from May 1 to Dec. 31, 1930, 19,000 vaccinations were performed. The number of vaccinations performed in 1931 has not been announced; but, judging by the quantity of lymph distributed, the number may be estimated at 5,800, so that from May, 1930, to May, 1931, one may assume that at least from 24,800 to 25,000 vaccinations have been performed with not a single case of encephalitis having been noted. It appears so far from the statistics that early childhood is the period least affected. Although the public health service does not state that postvaccinal encephalitis may not occur in the first year of life, nevertheless, in a comprehensive circular, it advises physicians to vaccinate children during the first year, preferably between the ages of 3 and 6 months. A further factor that has been noted, and is worthy of consideration, is that vaccination at that age causes but little general reaction and yet furnishes adequate protection. The fact that, for the space of a year, no case of postvaccinal encephalitis occurred is an indication that the cases of encephalitis are becoming more and more rare.

Accidents and Suicides

In the *Geneeskundige Tijdschrift der Rijksverzekeringsbank* of June, 1931, Dr. Van Lit discusses five cases of suicide (taken from the statistics of a health insurance society) that followed occupational accidents. When a person who suffers an accident commits suicide, it is reasonably certain that there is a relation of cause and effect, Van Lit stated. The first example that he cited was the case of a workman, aged 50, who had resumed his work after having suffered a fracture of the wrist, for which he had been allowed 50 per cent of disability. As he found himself awkward about his work, by reason of his injury, it seemed to him that he would never be able to work properly again. Then it was that thoughts of suicide came into his mind. The second case concerned a telephone operator, aged 29, who had suffered a compound fracture of the right leg and a fracture of the patella. Following the accident, mental disturbances were likewise observed. The patient committed suicide. It was found that he had suffered before the accident from psychopathic disturbances but that the accident had aggravated his mental condition. That was likewise the case in the third example cited, that of a boatman, aged 38, whose right thumb was about to be amputated. He fled and committed suicide. The fourth case belongs to the same category as the first. It concerned a lighterman who had suffered a fracture of the cuneiform bone without luxation. He was allowed 50 per cent disability but it seemed to him, likewise, that he would never be able to work properly, so he ended his life. The fifth case was entirely different. An engineer had suffered an injury of the right arm. Five weeks later, he committed suicide. It was found that he had already been an inmate of a psychopathic institution and likewise that he was wanted by the Belgian police for moral delinquency. In this case, it is certain that his injury alone did not lead to his suicide.

Report of Radiotherapeutic Institute

In the annual report for 1930, issued by the Radiotherapeutic Institute of Rotterdam, the medical director gives a detailed account of the method of treatment in cancer of the uterus. From his study on the combined treatment with surgery and radiology, he reached the following conclusions: 1. The value of prophylactic irradiation in its present form is as yet uncertain. Consequently, one has not the right to make an absolute demand for the application of this method. That can be done only when an increasing number of patients treated in that manner shall show that this treatment improves the state of health. 2. Preliminary surgical treatment, by means of electrocoagulation, encounters the same objections. In the case of conditions fairly well advanced, it may aid the radiologic treatment. When the development of the tumor is still in the beginning stage, it can be replaced by the application of radium needles. 3. The radical operation, following the preliminary ray treatment, is advisable in all cases in which the period of the first onset has passed; also in the grave cases when, of course, the ray treatment has improved the condition temporarily and has thus prepared the way for the operation. The radical operation is to be recommended likewise when the preliminary treatment with rays appears to have affected the clinical cure. The cure may, however, be only apparent; for the cancer cells that have escaped the fatal action of the rays may at any moment provoke a recurrence. At the institute, 239 patients affected with cancerous tumors have been treated, and in 121 a satisfactory result was achieved, while in 69 no results were obtained.

THE UKRAINE

(From Our Regular Correspondent)

Odessa, Jan. 24, 1932.

The Institute for First Aid

Before the revolution, the Odessa station of first aid existed, as the majority of such establishments, by means of philanthropic donations. Even before the revolution a number of stations ceased working because of the want of means; the Moscow station did not work from 1911 till 1917, and the Kiev station several times ceased its work only to resume it again. Under the soviet régime this situation has changed. The first aid stations, which were placed under the supervision of the commissariat of public health, received a solid material basis. The number of stations increased. At present there are sixteen stations in the Ukraine, three times more than existed before the revolution in all Russia. Every town with a population over 50,000 has its own station of first medical help. The Odessa station from the day of its foundation, April 20, 1903, has been open continuously. Special means for transportation and a medical and technical staff guarantee that aid will be administered promptly. Not more than half a minute elapses from the moment of the telephone call for help to the moment of the car's departure. In four minutes, on the average, the motor-car arrives at the place of the accident. Every motor-car is equipped with three boxes, one with surgical instruments for urgent aid and with dressing material, another with antidotes and instruments for lavage of the stomach, and a third with an apparatus for the injection of saline solution. In an average time of four minutes the patient receives at the place of the accident a transfusion of sterile saline solution. In every car there is oxygen and carbon dioxide, for purposes of resuscitation.

The work of the station was demonstrated in 1911 at the hygienic exhibition in Dresden, where the station received a diploma and the Esmarch medal. During its existence the Odessa first aid station has registered about 167,259 visits. It has become popular. From its material the station organized a scientific museum, the aim of which is to popularize and develop first aid. The material is divided into twelve departments. Great interest is shown in the department of traumatism, especially suicides. The material on the question of suicides is the largest collection in Europe. It contains about 10,000 detailed records of suicides in which questions of age, social conditions, education, place, means of suicide and motives are mentioned. These cards cover twenty-eight years. It is interesting to note the influence of social conditions on suicide. The number of suicides is diminishing every year, particularly among the working class; the number in the group of "others," on the contrary, is increasing.

A thorough investigation in the field of administering first aid is going on. The museum has worked out lists of poisons and antidotes and toxic gases. These lists are now used in all the dispensaries and stations of first medical aid in the Ukraine.

Death of Professor Golovin

The death of Prof. Serge Selivanovitch Golovin, a prominent Russian ophthalmologist, was reported, April 28, 1931, from coronary thrombosis. He was born in 1866 in Bolchov and graduated in 1889 from the Medical Faculty of the Moscow University. He was invited to join the clinic of eye diseases of the Moscow University as an assistant. In 1895 he was made lecturer in ophthalmology. In 1903 he was elected professor of ophthalmology at the Odessa University. He remained at Odessa eight years. In 1911 he became professor of ophthalmology at the Moscow University. Professor Golovin made many contributions to ophthalmology. He offered a cytotoxic hypothesis on the etiology of sympathetic ophthalmia and cataract, and a hypothesis of the vascular origin of glaucoma. He introduced an osteoplastic operation for empyema of the frontal sinus which is known the world over; also the ligation of the upper orbital vein as treatment of pulsating exophthalmos. He invented the roentgenographic method for detecting foreign bodies in the eye, and retrobulbar diaphanoscopy.

Professor Golovin wrote twelve monographs, all of which brought new data in the field of ophthalmology. He published "Clinical Ophthalmology" in 1924 and "Ophthalmotonometrical Examinations," the classic on statistics of blindness in Russia, in 1910. He was one of the founders of the Moscow Ophthalmologic Society, an honorary member of many Russian ophthalmologic societies, and a member of several international congresses and foreign societies. He founded a Russian ophthalmologic school and had many brilliant pupils. He wrote over 100 scientific works, many of which are printed in foreign languages. For Prof. S. S. Golovin's forty year jubilee of his medicoscientific work, the *Russian Ophthalmologic Journal* issued a special number. His name was known through all the world, particularly in the United States.

Marriages

Robert Church Knott, Sioux City, Iowa, to Miss Catherine Peck of Sioux Falls, S. D., January 18.

George A. Hennies, Chester, S. C., to Mrs. Elizabeth Bennett Atkinson of Holly Hill, February 10.

Charles Allen Perera, New York, to Miss Ruth Hoopes Brinton of Haddonfield, N. J., February 20.

Walter D. Higgins, Peabody, Mass., to Miss Alma Edith Knowles of North Andover, Nov. 28, 1931.

Benjamin G. Broghammer to Miss Lucille Murphy, both of Cedar Rapids, Iowa, January 14.

Benjamin Lynn Bridges, Ellaville, Ga., to Mrs. Ruth Scott Williams in Atlanta, February 9.

Ernest M. Tapp, Jr., to Miss Marjory McIntosh, both of Chillicothe, Ohio, Nov. 26, 1931.

Sidney S. Smith, Jr., to Miss Melissa Browne, both of Raleigh, N. C., Feb. 6.

Esther Cohen to Mr. Nathan M. Smolens, both of Philadelphia, Dec. 4, 1931.

Deaths

Willy Meyer ⊕ New York; University of Bonn, Germany, 1880; emeritus professor of surgery, New York Post-Graduate Medical School and Hospital; professor of clinical surgery, Woman's Medical College, New York, 1886-1892; member of the American Surgical Association, American Association for Thoracic Surgery and the American Urological Association; fellow of the American College of Surgeons; consulting surgeon to the Lenox Hill, New York Post-Graduate, New York Skin and Cancer and Montefiore hospitals, Hospital for Joint Diseases, New York Infirmary for Women and Children and the Glens Falls (N. Y.) Hospital; author of a recently published book on cancer; aged 73; died, February 25, of heart disease, immediately following a meeting of the New York Surgical Society, which he was attending.

George Clymer Stout ⊕ Philadelphia; University of Pennsylvania School of Medicine, Philadelphia, 1891; secretary of the Section on Laryngology and Otology, American Medical Association, 1900-1901, and member of the House of Delegates in 1902; member of the American Laryngological Association, and fellow of the American College of Surgeons; veteran of the Spanish-American War; consulting laryngologist and aurist to the Presbyterian Hospital; aged 69; died, January 27, in Ventnor, N. J., of heart disease.

Austin O'Malley, Philadelphia; Georgetown University School of Medicine, Washington, D. C., 1893; instructor of bacteriology at his alma mater, 1893-1895; professor of English literature, Notre Dame University, 1895-1903; author of "Thoughts of a Recluse," "Essays in Pastoral Medicine," and other books; aged 73; died, February 25, in St. Agnes' Hospital, of uremia and arteriosclerosis.

James Monroe Watkins, Troy, Ala.; Vanderbilt University School of Medicine, Nashville, Tenn., 1894; member of the Medical Association of the State of Alabama; member of the Alabama Board of Censors; past president of the Pike County Medical Society; physician-in-chief of the Alabama Baptist Orphanage; aged 61; died, January 25, in a hospital at Montgomery, of coronary occlusion.

Jeremiah Black Clayton ⊕ Colonel, U. S. Army, retired, Corning, Calif.; University of Maryland School of Medicine, Baltimore, 1893; entered the army as an assistant surgeon in 1897 and was promoted through the various grades to that of colonel in 1917; was retired in 1930 for disability in line of duty; aged 59; died, February 2, of chronic endocarditis and bronchopneumonia.

Abraham Albert Levine, Mount Vernon, N. Y.; Fordham University School of Medicine, New York, 1917; member of the Medical Society of the State of New York; served during the World War; on the staff of the Bikur Cholin Convalescent Home for Greater New York; aged 42; died, January 30, of acute dilatation of the heart and myocarditis.

Alfred F. White, Flovilla, Ga.; Georgia College of Eclectic Medicine and Surgery, Atlanta, 1892; member of the Medical Association of Georgia, and the state board of medical examiners; past president of the Butts County Medical Society; aged 76; died, Dec. 24, 1931, in a sanatorium at Atlanta, of suppurative pancreatitis.

Mallie Adkin Clark ⊕ Macon, Ga.; Bellevue Hospital Medical College, New York, 1890; fellow of the American College of Physicians; past president of the Medical Association of Georgia; formerly trustee and member of the faculty of Mercer University; aged 65; died, February 6, of myocarditis and endocarditis.

Frederick Andrew Jackson, Salida, Colo.; Denver College of Medicine, 1888; member of the Colorado State Medical Society; formerly on the staff of the Denver and Rio Grande Western Railroad Hospital; aged 67; died, January 22, in St. Joseph's Hospital, Denver, of cardiovascular renal disease.

Edward Michael Burns, Poughkeepsie, N. Y.; College of Physicians and Surgeons in the City of New York, 1894; member of the Medical Society of the State of New York; aged 60; on the staff of St. Francis Hospital, where he died, January 31, of carcinoma of the stomach.

Robert Earl Higdon, Brookhaven, Miss.; Tulane University of Louisiana School of Medicine, New Orleans, 1896; member of the Mississippi State Medical Association; aged 59; on the staff of the King's Daughters' Hospital, where he died, January 24, of acute nephritis.

⊕ Indicates "Fellow" of the American Medical Association.

Harold Main Vango, Edmonton, Alta., Canada; McGill University Faculty of Medicine, Montreal, Que., 1923; associate professor of medical jurisprudence and assistant professor of pathology, University of Alberta Faculty of Medicine; aged 36; died, Dec. 29, 1931.

Frederick Herbert Massecar ⊕ New York; University of the City of New York Medical Department, 1884; clinical visiting physician on the tuberculosis service, Harlem Hospital; aged 70; died, February 2, at Waterford, Ont., Canada, of myocarditis.

Warren Gray Sawyer, Madison, Maine; Medical School of Maine, Portland, 1884; member of the Maine Medical Association; formerly member of the state legislature and chairman of the board of health of Madison; aged 76; died, Dec. 16, 1931.

Frederick Nicholas Henry, Detroit; Medical Faculty of Trinity University, Toronto, Ont., Canada, 1892; Victoria University Medical Department, Coburg, Ont., 1892; aged 64; died, January 15, in the Grace Hospital, of diabetic gangrene.

Joseph John Scholtes, Sinking Spring, Pa.; Hahnemann Medical College and Hospital of Philadelphia, 1920; on the staff of the Homeopathic Medical and Surgical Hospital, Reading; aged 33; died, January 24, of pneumonia.

Gottlob Hartung, Cullman, Ala. (licensed, Alabama, 1892); member of the Medical Association of the State of Alabama; past president of the Cullman County Medical Society; aged 88; died, Dec. 17, 1931, of cerebral hemorrhage.

Roelf Barkema, Patton, Calif.; University of Groningen Faculty of Medicine, Groningen, Netherlands, 1923; member of the California Medical Association; aged 37; died, January 2, of peritonsillar abscesses and septicemia.

Michael Calvin Dinger ⊕ Morrisdale, Pa.; Western Pennsylvania Medical College, Pittsburgh, 1905; aged 55; died, January 10, at the Clearfield (Pa.) Hospital, of peritonitis, following an operation for appendicitis.

James Wesley Tucker, Lindsay, Okla.; Vanderbilt University School of Medicine, Nashville, Tenn., 1892; member of the Oklahoma State Medical Association; aged 71; died, January 21, of chronic myocarditis.

John Vance Greene, San Diego, Calif.; Kansas City Medical College, 1897; member of the California Medical Association; aged 59; died, Dec. 24, 1931, of diffuse arteriosclerosis and coronary occlusion.

Edwin Blair Hanna ⊕ York, Neb.; Chicago Homeopathic Medical College, 1900; member of the city council; on the staff of the Lutheran Hospital; aged 63; died suddenly, January 5, of cerebral hemorrhage.

Malvin V. Replogle, Bryan, Ohio; Starling Medical College, Columbus, 1894; member of the Ohio State Medical Association; for ten years health officer of Williams County; aged 61; died, Dec. 31, 1931.

Samuel R. Harbin, Canton, Ga.; Georgia College of Eclectic Medicine and Surgery, Atlanta, 1898; member of the Medical Association of Georgia; aged 59; died, January 26, of carcinoma of the bladder.

Jeremiah P. Worsham, Barry, Texas; Southwestern University Medical College, Dallas, 1904; member of the State Medical Association of Texas; aged 60; died, Nov. 13, 1931, in a hospital at Dallas.

Elna Cicillia Bjork, San Diego, Calif.; Grand Rapids Medical College, 1900; aged 73; died, Nov. 13, 1931, in the San Diego County Hospital, of lobar pneumonia and cardiovascular renal disease.

Henri Lambert, Brunswick, Maine; School of Medicine and Surgery of Montreal, Que., Canada, 1906; member of the Maine Medical Association; aged 50; died, Dec. 30, 1931, of carcinoma of the liver.

John G. Chambers, Sr., Birmingham, Ala.; University of Nashville (Tenn.) Medical Department, 1898; aged 58; died, February 6, in the Norwood Hospital, of arteriosclerosis and subacute cholecystitis.

Henry Hall James, Jr., Detroit; Detroit Homeopathic College, 1910; member of the Michigan State Medical Society; aged 51; was found dead in his garage, January 24, of carbon monoxide poisoning.

Edward Fowler Hurd, New York; College of Physicians and Surgeons in the City of New York, 1883; member of the Medical Society of the State of New York; aged 70; died, Dec. 26, 1931.

James Alberdean Young, Britton, Okla.; College of Physicians and Surgeons, Keokuk, Iowa, 1894; aged 70; died, Dec. 18, 1931, at the home of his daughter in Oklahoma City, of heart disease.

John D. Lindores ⊕ Stevens Point, Wis.; American Eclectic Medical College, Cincinnati, 1887; on the staff of St. Michael's Hospital; aged 72; died, January 27, of pernicious anemia.

Barton Lincoln Baker, Los Angeles; Hahnemann Medical College and Hospital of Philadelphia, 1887; aged 71; died, Dec. 10, 1931, of carcinoma of the stomach and arteriosclerosis.

John Walter [illegible] th, Miss.; Memphis (Tenn.) Hospital [illegible] aged 50; died, January 9, in the Col [illegible] of lobar pneumonia.

Henry C. Miller, Greentown, Ind.; Kentucky School of Medicine, Louisville, 1883; member of the Indiana State Medical Association; aged 82; died, January 14, of arteriosclerosis.

William Campbell Allen, Morning Sun, Iowa; State University of Iowa College of Medicine, Iowa City, 1881; aged 75; died, January 4, in Long Beach, Calif., of angina pectoris.

Frank R. Morath, Columbus, Ohio; University of Wooster Medical Department, Cleveland, 1878; aged 74; died, January 16, in the Masonic Home, Springfield, of arteriosclerosis.

Horatio Page Gatchell, Jr., Los Angeles; Hahnemann Medical College and Hospital, Chicago, 1875; aged 84; died, Nov. 29, 1931, of cerebral hemorrhage and influenza.

Adolpho Alfonso Luria, Chicago; College of Physicians and Surgeons of Chicago, 1895; aged 64; died, February 5, of chronic nephritis, myocarditis and arteriosclerosis.

Loring Sawyer Lombard, South Portland, Maine; Medical School of Maine, Portland, 1893; member of the Maine Medical Association; aged 61; died, January 10.

Henry North Sloan, Ninety Six, S. C.; University of South Carolina Medical Department, Columbia, 1869; Civil War veteran; aged 84; died, Dec. 25, 1931.

John Henry Gaines, Newport, Vt.; University of Vermont College of Medicine, Burlington, 1884; aged 76; died, January 10, in Bradenton, Fla., of uremia.

Hugh Harrison Conroy, Pasadena, Calif.; Louisville (Ky.) Medical College, 1891; aged 66; died, Dec. 14, 1931, of tabes dorsalis and chronic interstitial nephritis.

Archibald Lawson, Greensboro, Ala.; University of the City of New York Medical Department, 1876; bank president; aged 79; died, January 11, of smallpox.

Daniel Harris Squires, Ashville, Ohio; Columbus Medical College, 1880; also a druggist; aged 81; died, January 4, in Sarasota, Fla., of dilatation of the heart.

Bernard Aloysius McDermott, Omaha; Northwestern University Medical School, Chicago, 1903; aged 52; died, January 13, in St. Catherine's Hospital.

Joseph Edward Rogers, Rocksprings, Texas; College of Physicians and Surgeons, Memphis, Tenn., 1907; aged 62; died, Dec. 16, 1931, of heart disease.

Margaret Vaupel Clark, Long Beach, Calif.; Hahnemann Medical College and Hospital, Chicago, 1893; aged 78; died, January 2, of cerebral hemorrhage.

Greene Warren McConathy, Eads, Tenn.; University of the South Medical Department, Sewanee, 1909; aged 47; died, Dec. 15, 1931, of heart disease.

James Harrison Clark, Pacific Grove, Calif.; Bellevue Hospital Medical College, New York, 1872; aged 90; died, Nov. 11, 1931, of senility.

Earl Harlan, Harrison, Ohio; Medical College of Ohio, Cincinnati, 1898; aged 60; died, Dec. 25, 1931, of a self-inflicted incised wound.

Liston B. Johnson, Georgetown, S. C.; Baltimore Medical College, 1897; aged 57; died, January 2, in Fort Leavenworth, Kan., of pneumonia.

Gordon Hall Rutherford, Chatham, Ont., Canada; University of Toronto Faculty of Medicine, 1927; aged 31; died suddenly, January 4.

John F. Costello, Howard, Kan.; Columbus Medical College, 1880; aged 79; died, January 14, of cardiovascular renal disease and uremia.

Hollis L. Courtney, Tulsa, Okla.; Ensworth Medical College, St. Joseph, Mo., 1907; aged 62; died, Dec. 16, 1931, in a local hospital.

William M. Walker ⊕ Boston; Tufts College Medical School, Boston, 1894; aged 66; died, January 29, of lobar pneumonia.

Edwin A. Hecker, New Madison, Ohio; Columbus Medical College, 1878; aged 81; died, January 26, of heart disease.

Henry Illoway ⊕ New York; Miami Medical College, Cincinnati, 1869; aged 84; died, January 15, of uremia.

Correspondence

INTRAVENOUS INJECTION OF DEXTROSE SOLUTIONS

To the Editor:—I am writing you on account of my astonishment in reading the editorial concerning the "injection" intravenously of dextrose solution (THE JOURNAL, Dec. 12, 1931). I had thought that that method had long since given place to the continuous infusion at the physiologic rate of delivery.

A rich experience has taught me that the objections which you mentioned in your editorial are entirely obviated by the adoption of this more rational procedure, mention of which was entirely omitted in your editorial.

G. A. HENDON, M.D., Louisville, Ky.

To the Editor:—May I suggest that your editorial comments on intravenous injections of dextrose as a therapeutic procedure in the Dec. 12, 1931, issue of THE JOURNAL are perhaps more critical than the facts of the investigations referred to by you may warrant.

So general is its use that great quantities of dextrose solution in various degrees of concentration are being given in hospitals and in homes daily without any unfavorable reactions. In many clinics, reactions of any such type are practically unknown.

Nevertheless the tendency of human nature seems to be to place the blame for any reaction that does occur on the fact of its being a dextrose injection, until the term "glucose reaction" has actually come to be a poor alibi in many instances for failure to observe the fundamental rules of the procedure.

A review of the studies on which your editorial is based shows that Stuter and Lang (*Arch. f. exper. Path. u. Pharmakol.* **154**:50, 1930.) found their most significant changes in the chemical examination of the blood following dextrose injections, as you pointed out, in patients with cardiac decompensation, a condition to which certain such changes are common from the disease itself. In the fatal case reported by Askey and Hall (*California & West. Med.* **32**:394 [June] 1930) appears the significant statement that "the resident physician was ordered to give the patient, slowly, 1,000 cubic centimeters of 10 per cent glucose solution intravenously," so that no specific information as to the velocity of the injection is available. One may safely assume that the average intern's interpretation of "slowly" will not reach two hours, which by actual computation is the minimum time to be consumed for such an injection (1,000 cc. of 10 per cent solution) to an average adult at 0.8 Gm. per kilogram of body weight per hour.

This may have been one of the velocity reactions described by Hirshfeld, Hyman and Wanger (*Arch. Int. Med.* **47**:259 [Feb.] 1931), or may have been from the amount of the dextrose being excessive (Titus and Lightbody: Therapeutic Dose of Dextrose, *Am. J. Obst. & Gyn.* **18**:208 [Aug.] 1929), causing an overstimulation of the pancreas and endogenous hyperinsulinism (Thalhimer, Raine, Perry and Buttles: Effect of Injections of Dextrose and of Insulin and Dextrose on Blood Sugar, THE JOURNAL, Aug. 7, 1926, p. 391). In this connection it is significant that this reaction occurred as those from hyperinsulinism do, not during but after the injection. It is of course possible that thrombosis and embolism resulted from the injection as the authors suggest, but this is fortunately rare in the total of all injections being given. The three cases of Ylanan (*J. Philippine Islands M. A.* **10**:440 [Oct.] 1930), which you cite as further examples of death from dextrose injections, are obviously deaths from (1) dextrose in "old, standing, distilled water, which most likely was contaminated, the solution boiled and golden yellow in color, not clear, and caramelized"; (2) from dextrose in "rain water as the solvent . . . boiled . . . and caramelized"; (3) from a dextrose solution "prepared by a local pharmacist, . . . made from impure glucose dissolved in distilled water several months old, . . . boiled, turbid and yellow." These were not "glucose reactions" but "carelessness reactions."

Obviously, if a therapeutic measure which has proved so generally useful in so many conditions is to be condemned because bad results follow faulty technic, then we should discard nitrous oxide anesthesia, for example, because of an occasional bad result from a technical error, or never give a hypodermic injection because a dirty one causes an abscess.

If dextrose solutions are properly prepared and properly given, reactions are almost entirely avoidable (Titus and Dodds: Causes and Preventions of Reactions from Glucose Injections, *Am. J. Obst. & Gynec.* **14**:181 [Aug.] 1927). They should not be made or given by any one who does not know this.

A pure dextrose, in freshly distilled water, properly sterilized, given no faster than at the physiologic rate, heated instead of cooling, and in not more than the therapeutic dose, will seldom give anything but beneficial results when properly indicated.

Bizarre suggestions such as that which you cite of the intravenous injection of raw orange juice are too absurd to be discussed, and the injections of sucrose which are referred to likewise have little in common with dextrose.

Please do not misconstrue what I have written as indicating disapproval of your timely editorial. Its note of warning is sorely needed as a brake on our enthusiasm. I felt merely that the discreditable causes for some of the more outstanding of the bad results had not been sufficiently emphasized, whereas more stress than necessary seemed to have been placed on the more uncommon causes of reactions following dextrose injections.

J. STUART LAWRANCE, M.D., Philadelphia.

Queries and Minor Notes

ANONYMOUS COMMUNICATIONS and queries on postal cards will not be noticed. Every letter must contain the writer's name and address, but these will be omitted, on request.

BENIGN HYPERTENSION

To the Editor:—What is the significance of an increase in the diastolic pressure and an increase in the systolic pressure with a negative urinary examination and negative chemical examination of the blood in a patient, aged 50. The blood pressure is 180 systolic and 125 diastolic. This is a rather broad question, of course, but I would appreciate your discussion of it. Please omit name.

M.D., North Carolina.

ANSWER.—A rise in blood pressure of the type described would probably fall in the group of primary or benign hypertension. If, as is usual, in this condition it has existed over a period of several years at least, there are some secondary changes usually present. The heart will show moderate left ventricular enlargement, and the palpable arteries a thickened wall with some tortuosity, but without the beading more characteristic of the senile type of arteriosclerosis. Roentgen examination may show patchy calcification of the vessels. There are usually definite arteriolar changes as well. These may be shown clinically by examination of the fundi, in which the arteries are narrowed, show the so-called copper wire reflex, and definitely indent the veins where they cross or come in close contact. The same arteriolar changes occur in the kidney and, if extensive, may involve some of the glomeruli in hyaline degeneration and sclerosis. Slight albuminuria may occur but usually does not. The available tests of kidney function are not sufficiently sensitive to measure the amount of glomerular damage unless the disease process runs a course of many years and the arteriolar changes are of extreme grade. This arteriolosclerosis may be demonstrated by biopsy elsewhere in the body.

The etiology is obscure. The origin of the condition is probably functional and the organic vascular changes are a secondary response to the increase in pressure. This has not been proved but seems the most likely hypothesis.

The course is long, and with a pressure no higher than that mentioned at the age of 50, if the vascular system is competent, the outlook is good. The complications that arise are, first, cardiac failure, and, second, cerebral hemorrhage or thrombosis. Disease of the coronary arteries may enter the picture. If vascular failure does not occur and the patient lives sufficiently long, renal impairment may become evident. The pathologic terms applied then to this condition are primary contracted kidney, arteriosclerotic kidney or benign nephrosclerosis.

Blood pressure readings in such a patient taken frequently show a well marked fluctuation with or without treatment. They respond, by rising and falling, to evironmental changes in much the same way as a normal individual will. The systolic-diastolic levels usually retain the same approximate relationship. A sudden marked drop, especially with a decrease in pulse pressure, usually is indicative of myocardial impairment or coronary disease.

If the functional element is still active there may be an appreciable fall as the result of treatment, especially relaxation, rest, a normal diet, weight reduction if needed, and correction of faulty habits. Drug therapy is more or less uncertain and unsatisfactory. The best results are obtained by corrective measure, but no permanent marked fall in pressure is to be expected if anatomic changes are well advanced.

EPICONDYLITIS, OR OSGOOD'S "TENNIS ELBOW"

To the Editor:—I have a patient, a painter by trade, who gives a history of falling and hurting his right shoulder and arm. He complains of a severe pain in the right elbow, mostly in the region of the external epicondyle. He has much pain at night. He cannot use his hand for grasping anything, even an empty cup, so intense is the pain. On examination I found the elbow joint free for motion and painless while moving. Roentgenograms are negative. There is much tenderness in the region of the external epicondyle. The pain seems to be a real one; i. e., it seems to me that the patient really has it. It has been suggested to me that this condition resembles a typical case of Osgood's "tennis elbow" or external epicondylitis. May I ask you to inform me what are the typical signs of epicondylitis? Does my case seem to you to be one of that kind? What can you suggest for therapy? Where can I find a description of this condition? The circumference of the right arm in the region of the elbow is from 0.5 to 0.75 cm. greater than that of the left arm.

Judah Minkin, M.D., Bronx, N. Y.

Answer.—The description would place this case immediately in the group considered under the term "tennis elbow," or external humeral epicondylitis. The condition called tennis elbow is of fair frequency as a cause of disability of the elbow. This condition has been variously ascribed to muscular, bursal, periosteal, ligamentous and synovial disturbances. The radiohumeral bursa lies immediately distal to the external epicondyle deep to the common origin of the extensor group and between this and the radiohumeral joint.

Trethowan believes that tennis elbow is always a traumatic synovitis of the radiohumeral joint. He does not believe that sepsis is a factor, as his eight patients were all cured by simple removal of the fringes. Ogilvie believes that the condition occurs not only in tennis players but also in fly-fishers, golfers, saber fencers and workers with a hammer. He describes a definitely localized tender spot on the outer side of the joint in the region of the external epicondyle. He found that clenching the fist is painful. He believes that the condition is due to a tearing of muscle fibers at their origin from the bone and in some cases to separation of the periosteum.

Mills believes that the condition is similar to a displaced cartilage in the knee caused by a subluxation of the radius or displacement of the orbicular ligament.

Carter in the *Journal of Bone and Joint Surgery* (**7**:553 [July] 1925) describes epicondylitis as a condition characterized by pain originating in and about the lateral humeral condyle, radiating down the forearm and hand, giving rise to disability of varying degrees. The most common pathologic changes are localized periostitis or bursitis.

Golf elbow results from strain of the flexor carpi ulnaris due to forcible abduction of the wrist causing tension on this muscle.

The chief symptoms of tennis elbow are tenderness in the region of the external epicondyle of the humerus and weakness of the muscles of the forearm. There is usually an area of tenderness over the external epicondyle of the humerus or over the head of the radius. Movements of the elbow and movements of the forearm, especially pronation and supination, cause pain referred to the external epicondyle.

The Mills test is carried out as follows: If the wrist and fingers are fully flexed and the forearm is pronated, complete extension of the elbow is restricted and painful.

This condition is referred to in the American literature as Osgood's radiohumeral bursitis or epicondylitis. Osgood's article is one of the best descriptions of this condition. It appeared in the *Archives of Surgery* (**4**:420 [March] 1922). Osgood had the pathologic condition himself and while he was being operated on under local anesthesia he analyzed the pathologic anatomy and wrote a description of it. He described the bursa as the radiohumeral bursa which appears when a split is made in the conjoint tendon of the extensor muscles over the radiohumeral joint. The pathologic changes are thought to be due to an inflammatory reaction in the connective tissue plane located beneath the conjoint tendon of the extensor muscles between this tendon and the tip of the epicondyle, the origin of the supinator radii brevis and the radiohumeral joint.

Various methods of treatment have been advised, including the hot cautery needle, injection of camphor and phenol, immobilization in plaster, immobilization in splints, and operation which consists of removal of the bursa. Strapping the hand, wrist and elbow so that the forearm is midway between pronation and supination is usually helpful. Alcohol injections have been advised. An adhesive plaster dressing has been advised. A similar pad for compression over the bursa has been advised. He places the arm in the attitude previously described, forces it into complete extension, making firm pressure with the thumb over the sensitive spot. In some cases there is an audible click when the resistance gives way.

An excellent description of this condition will be found in the following textbooks:

Jones, Robert; and Lovett, R. W.: Orthopedic Surgery, ed. 2, New York, William Wood & Co., *1929. On page 64 the authors quote from the article by Robert B. Osgood.*
Campbell, W. C.: Textbook on Orthopedic Surgery, Philadelphia, W. B. Saunders Company, 1930, p. 534.
Whitman, Royal: Treatise on Orthopedic Surgery, Philadelphia, Lea & Febiger.

The patient referred to in the query should have repeated roentgenograms made to see whether any other pathologic condition is demonstrable.

CLIMATE FOR PATIENT WITH HYPERTENSION AND BRONCHITIS

To the Editor:—I am writing you for information pertaining to the choice of surroundings for a patient of mine. She is suffering with hypertension (*220/120*), is 65 years of age, and in addition has a chronic bronchitis of long standing. What effects would marked changes of altitude have on this patient and which is the more desirable: Would the salty air of an ocean beach have a deleterious effect? Would she be comfortable in a climate such as exists at Hollywood, Calif.? How should such a patient be treated and what ought one recommend in the way of surroundings?

Florian J. Brylski, M.D., Buffalo.

Answer.—Marked changes of altitude are not desirable in a patient of this type, and in general an altitude of sea level or only slightly above would be best. If changes of altitude are unavoidable, during the time of staying in an increased altitude the patient's activities should be markedly restricted until she is acclimatized. Because of the long standing chronic bronchitis, moisture and dampness of an ocean beach might have some deleterious effects, and in general she would probably be more comfortable in a dry, warm, relatively dust and moisture free climate, such as Arizona, New Mexico, and the desert regions of California. The treatment of such a patient should be directed toward the hypertension and bronchitis, the former being treated by the usual dietary and medicinal measures, including a protein poor, salt free diet; the cautious administration of bromides; phenobarbital and small amounts of sodium thiocyanate; the latter, by sedatives for coughing, and various expectorant mixtures.

PHOSPHATURIA

To the Editor:—I have a patient with a resistant phosphaturia with alkaline urine, to whom I have given diluted nitric acid, acid sodium phosphate and ammonium chloride on different occasions. Would you kindly suggest something that will make the urine acid, as this treatment has failed. *Kindly omit name.*

M.D., New York.

Answer.—In the treatment of phosphaturia it is important to remember that frequently the condition is a result of nervous instability. Treatment then must be directed at the patient's nervous system, for which purpose bromides may well be used. Other measures usually employed in treating neurotic individuals are valuable, such as sufficient rest, hydrotherapy and relief from worries of any sort. If, as so frequently happens in cases of phosphaturia, the patient is in a condition of combined physical and nervous fatigue, proper regulation of life is necessary in order to avoid the strain that produces the fatigue. Not infrequently the mere knowledge of the presence of phosphaturia and the fright incident to seeing a cloudy urine produces a vicious circle. When this occurs, the wise physician will minimize the importance of the phosphaturia rather than pay too much attention to its therapy.

In addition, an acid forming diet low in calcium is advisable. Such calcium-poor foods as meat, bread and the cereal grains should be eaten liberally, and other foods which are rich in calcium, such as milk and green vegetables, should be avoided or at least decreased in quantity. Almost any kind of inorganic or organic acid could be used. For further information regarding the acid forming foods and calcium value of diets, any good textbook on nutrition and diet may be consulted.

TUBERCULOUS INFECTION AND TUBERCULOUS DISEASE

To the Editor:—I should like to have a clear and definite understanding between "tuberculous infection" and "tuberculous disease." Also is tuberculosis usually contracted during childhood, becoming active in early adult life, or is it more likely that it is contracted during early adult life and immediately becomes active? Is it true that childhood infection often establishes immunity and protects during later life? What is known about tuberculous immunity and how can it be proved?

C. V. Little, M.D., Sistersville, W. Va.

Answer.—Tuberculous infection is the entrance into the human body of tubercle bacilli. This may occur by inhalation, ingestion or inoculation. Tuberculous disease is the change occurring in body tissue incidental to the growth and development of tubercle bacilli in such tissue. Tuberculous infection is usually contracted during childhood, especially in child life in urban centers, because of the widespread presence of tubercle bacilli in congested areas. Such infection in childhood may or may not result in primary tuberculosis, which in a majority of instances may heal, leaving a residual disease focus. This may subsequently be activated in early adult life, or a new infection may take place in adult life which may cause disease at that time, without any previous childhood infection. Childhood infection frequently establishes sensitization to tubercle, which is of some value in the fixation of a tuberculous process later in life. It, however, does not offer more than a possible relative immunity. Tuberculosis immunity is only relative. Skin tested with tuberculin has in many instances indicated a marked sensitization by a severe reaction which occurred when such tests were made. This reaction becomes markedly lessened or may disappear temporarily, in the presence of an acute exanthematous disease, and may be reestablished shortly after the exanthematous eruption has disappeared. This has been taken as an indication of temporary destruction of immunity.

THE IMPORTANCE OF DECIDUOUS TEETH

To the Editor:—I have two references from Queries and Minor Notes on the question of extraction of deciduous teeth which contradict each other. A similar problem has come up in my own practice and I should appreciate your advice as to which is correct. A physician from California asked about a child, aged 13 months, who had lost three upper incisor teeth in an accident. The reply was: "The loss of deciduous teeth is not likely to have any influence on the development of the jaw. The development and eruption of the permanent teeth are the factors that determine growth of the jaw. The permanent teeth will probably erupt in proper position and the only disagreeable phase will be the absence of teeth until the child is about 6 years old." Dr. Brakebill asked about his 19 months' old daughter who broke one of her upper incisor teeth. The reply in part was: "One should plan as best one can to meet developmental conditions that will arise during the next six or eight years. The space occupied by the broken tooth should be maintained in order that there will be room for the permanent tooth when it erupts. If this is not done, the adjacent teeth approximate each other and proper growth of the maxilla is retarded." Some details are then given for maintaining the space left by the missing tooth.

M. Bernard Brahdy, M.D., Mount Vernon, N. Y.

Answer.—Attention is called to the conditions of growth of the jaws in the incisor region. At about the third year, the deciduous incisor teeth, upper and lower, begin to move apart and continue to do so until they are lost. During this period, the permanent upper incisors are moving downward (the lowers upward) and they appear to direct the growth of the bone in this region. The permanent central incisors are usually formed in the bone with their edges to the front; they gradually rotate as they approach eruption, and thus cause the bone to grow. This is a part of the process of widening the dental arch. It is not necessary, therefore, that space retainers be used for deciduous incisor teeth that are lost by accident or otherwise before the time when they would be normally shed. If one is lost, the space will gradually become wider.

On either side of the jaw, where the deciduous molar teeth are situated, the conditions are far different. If the deciduous first molar is lost, the deciduous second molar may move forward, reducing the space. If the deciduous second molar is lost before the first permanent molar erupts, the permanent molar will likely erupt too far forward. It is important, therefore, to use space retainers when deciduous molars are lost too early.

FLATFOOT

To the Editor:—I have a patient who has an acute flatfoot of the second degree. He has been wearing arch supports for five months. How long should he continue to wear them before he tries to go without them? Please omit name and address.

M.D., Tennessee.

Answer.—The patient should get away from metal plates as soon as possible, and should substitute any one or combination or all of the following:

1. Adhesive strapping of the foot and ankle.
2. High lace shoes with rigid shank, straight last and round toe.
3. Modified heels and sole of the shoes (the most common being three-eighths inch rise on the inner border of the heel and one-eighth inch rise on the outer border of the sole).
4. Resilient support to be inserted in the shoe for the longitudinal arch.
5. Special longitudinal arch exercises.
6. Massage of the feet twice daily.
7. Contrast foot sprays.
8. Reduction in weight, if there is indication for it.

CONSUMPTION OF RIVER WATER AND INCIDENCE OF DISEASES

To the Editor:—The water supply of this city is taken from the Missouri River about 20 miles below the discharge of the sewage of a city of some 80,000. The water is extremely turbid and is purified in settling tanks with the help of rather ill regulated additions of alum and lime. No filter is used, and the tanks where the impurities are supposed to settle are not covered, so that when a strong wind blows over the hill where the tanks are situated the settling is even less thorough than under more favorable circumstances. After leaving the settling tanks the water gets an ill regulated addition of solution of chlorinated lime, which is supposed to kill all the bacteria. Often the man in charge appears to use an overdose of this disinfectant, so that our drinking water frequently has a decided smell and taste of bleaching powder. Can it be said that the constant use of drinking water that often contains hypochlorites and always a high percentage of chloride and sulphate of calcium is detrimental to the general well being? Is such constant absorption of hypochlorites, etc., either directly or indirectly detrimental to health? Or is there a lowering of the resistance to diseases? Or might it not be said that the energy or vitality used up to counteract the detrimental effect of such water is lacking for other purposes, such as business enterprises or community life? I am considering the possibility of starting a movement with the end of improving the management of the water works. But before doing so I would like to have an authoritative opinion from a recognized organization whether or not my ideas are defensible. Please omit name and city.

A. B., Kansas.

Answer.—From the description of the water supply as given, it would appear that the consumers are not getting adequate protection against water-borne diseases. Some indication of the truth of this surmise might be obtained from a study of the incidence of intestinal infections in the city or even from a study of the typhoid incidence and death rate alone. There is no evidence that waters containing chlorides or sulphate of lime are in any way detrimental to health or that they produce any physiologic strain which might predispose to disease. Neither is there any evidence that the constant consumption of water containing hypochlorites of sodium or calcium in amounts generally used for the treatment of public water supplies is detrimental to health, although it may be disagreeable. No statement is made as to the amount of hypochlorite added or the amount of hypochlorite remaining in the water supply when it reaches the consumer, so that a direct and definite answer is difficult to make. Experience in many parts of the country has shown that the best method of preparing a river water for human consumption is by screening or sedimentation followed by the addition of alum or other coagulant together with some alkali if necessary, filtration and final chlorination. The alum treatment followed by filtration takes care of the greater number of bacteria and the chlorination gives the necessary added factor of safety.

SUCTION OF NASAL SINUSES

To the Editor:—What is the best method of suction in the treatment of nasal sinuses? What technic would you advise? Where can I find a description of the procedure in detail? Please omit name.

M.D., New Jersey.

Answer.—It is difficult to state which method of suction is best. It is possible to apply satisfactory suction by means of a small rubber hand bulb to which is attached either a glass or an aluminum tip. By compressing the bulb and placing the tip in one nostril and tightly closing the other, having the patient say some word with the sound of k in it, at the same time releasing the pressure on the bulb, adequate suction will be provided. Water suction pumps are also convenient and quite powerful. The pump itself is attached to the faucet and the tubing with a nasal tip leads from there to the nose. The degree of suction is regulated by the speed of the water passing through the pump. Electric motor suction pumps are also available for use in offices and hospitals. One method is probably as good as another provided care is taken not to use too powerful a suction for fear of causing bleeding or severe pain. It should be remembered from the physics involved that it is impossible by suction alone to evacuate a cavity that has fluid in its depth unless there is some way of getting air into the cavity so that the fluid is displaced by the air. Using this suction with rather frequent interruptions will allow air to enter the sinus and displace the fluid. When the pus escapes from the sinuses into the nose, suction of course can easily remove it. The hand suction is most easily controlled and is therefore perhaps best from that standpoint. The patient himself can apply suction at home if properly instructed. The subject of nasal suction is discussed in most of the textbooks dealing with the nose and throat, such as those by Ballenger and by Phillips.

CAUTERIZATION OF CERVIX

To the Editor:—Will you be so kind as to describe in detail the office procedure of cauterizing the uterine cervix. I have in mind the cauterization of erosions and old lacerations with the Post cautery, and I can find nothing on the subject aside from the mere mention of the procedure. I am particularly anxious to know the details of the anesthesia necessary—the best anesthetic to use and the local application when the procedure is done entirely under local anesthesia.

J. Marine Kercheval, M.D., Wolcottville, Ind.

Answer.—Cauterization of the cervix usually causes only moderate pain unless it is necessary to use the cautery knife high within the cervical canal. In the latter case a local application of 5 per cent procaine hydrochloride, with or without a preliminary hypodermic injection of 0.008 Gm. (one-eighth grain) of morphine sulphate usually suffices. In patients who are unusually sensitive or in whom the lesion to be treated is difficult of access, nitrous oxide-oxygen anesthesia or infiltration local anesthesia with 1 per cent procaine hydrochloride should be resorted to; some employ ethylene in these cases, but ethylene is hazardous in patients on whom a cautery is used. The technic of endocervical cauterization consists in making four or five radial cuts. Beginning as high as necessary, often at the internal os or above, one pulls the glowing knife blade toward the external cervix, cutting into the mucosa during its withdrawal. Three or four similar additional cuts are usually made.

In the treatment of a raw everted cervix or an erosion of the cervix, multiple parallel anteroposterior cuts are usually made at distances of approximately 0.5 cm apart throughout the affected area.

SUDDEN LOSS OF VISION

To the Editor:—A man, aged 45, came to me because of inability to see with his left eye. One week previously he had gone to an ophthalmologist, who told him that he had a hemorrhage in the left eye. On physical examination I found a moderate obesity, and hypertension of 240/100. Examination of the fundi revealed arteriosclerotic blood vessels but no evidence of any other pathologic changes. No albuminuric retinitis, hemorrhage, optic atrophy or visible pathologic changes of the central arteries were present. Urinalysis showed a moderate degree of fixation (1.012, 1.014, 1.012) but was otherwise negative. The chemical composition of the blood was within normal limits. What accounts for the persistent symptoms in the left eye and absence of other symptoms? What would you suggest for treatment? Please omit name.

M.D., New Jersey.

Answer.—Before any diagnosis can be made, visual fields, both peripheral and central, should be taken, and from these, in all probability, a clue may be derived. There might be a retrobulbar neuritis; there might be sclerosis of the basilar cerebral vessels with pressure on the optic nerves; there might be a cortical hemorrhage; there might be any one or two of a number of conditions that could cause loss of vision. Treatment cannot be suggested until a diagnosis has been made.

ACROMEGALY AND ANTERIOR PITUITARY EXTRACT

To the Editor:—What is the possibility of inducing acromegaly in patients who are receiving large doses of anterior pituitary substance for the treatment of alopecia, as advocated by Bengtson? Please omit name.

M.D., Michigan.

Answer.—While certain investigators have experimentally created acromegaly in animals by massive doses, it is the consensus of specialists in endocrinology that acromegaly is a specific eosinophilic tumor. Overdosage of pituitary by hypodermic or oral usage usually manifests itself by headache or visual disturbance before any detrimental influences are thought to occur.

ECLAMPSIA

To the Editor:—Does a diagnosis of eclampsia imply pathologic changes in the liver? If necropsy does not reveal any pathologic changes in the liver, is one justified in making a diagnosis of eclampsia?

Frederick H. von Hofe, M.D., East Orange, N. J.

Answer.—If a patient has all the clinical (convulsions, hypertension, headaches, edema, visual disturbances, vomiting) and laboratory (albuminuria, cylindruria) evidences of eclampsia, a diagnosis of this disease should be made even if a necropsy fails to reveal the so-called pathognomonic changes in the liver. The exceptions to this rule are the cases in which all the clinical signs and symptoms of eclampsia are present but in which at necropsy an unsuspected etiology for these symptoms is found, such as uremia, cerebral apoplexy, sinus thrombosis or other conditions. Many authorities believe that there are distinctly characteristic changes in the liver in most but not in all women who die of eclampsia. Macroscopically the lesions consist of irregularly shaped red and white areas which arise near the smaller portal vessels and are scattered throughout the entire liver. When the liver is cut across, these areas give the organ a mottled appearance. Microscopically the areas are seen to be necrotic and they involve the periphery of the individual lobules and the portal spaces. The necrosis is due to degeneration which results from thrombosis of the smaller portal vessels. Williams was of the opinion that this lesion does not occur in any disease other than eclampsia, but it is not always present in this disease. Many pathologists, notably Pick, deny that the lesions described are limited to the portal areas and maintain that these changes may be found in any part of the liver.

STRAMONIUM IN PARKINSON'S DISEASE

To the Editor:—Inquiry has been made of me concerning the use of stramonium as a treatment for Parkinson syndrome occurring in a case of epidemic encephalitis. I am more or less unfamiliar with the treatment of this type of case by this drug. Will you please give me such information as you may have on the subject and advise me as to the most suitable preparation of stramonium, the dosage, the length of time administered, habit forming propensities and untoward effects, if any.

C. C. Atherton, M.D., Union Grove, Wis.

Answer.—The preparation most commonly used is tincture of stramonium U. S. P. in doses starting with 1 cc. (15 minims) three times a day, gradually increased by 0.3 cc. (5 minims) to the dose at the end of each week until relief is secured. The relief is temporary only, and the administration must therefore be continued indefinitely. The drug is not habit forming in the sense that there is difficulty in withdrawal. The untoward effects are similar to those of the belladonna alkaloids, particularly dry mouth and disturbance of vision due to dilatation of the pupils and paralysis of accommodation. Discussion of the method of therapy will be found in Cottrell, S. S.: Encephalitic Sequelae and Their Treatment, *American Journal of Psychiatry* **11**:253 (Sept.) 1931.

TREATMENT OF ACNE

To the Editor:—I encounter the usual run of cases of acne in young people that one finds in general practice. I have tried the hygienic measures, the local applications, ultraviolet rays, vaccine (both stock and autogenous), and in fact all the usual methods excepting the x-rays, with little or no success in treatment. The use of gold sodium thiosulphate has been suggested as a possible treatment. If so, how is it used? Are there any suggestions other than those already mentioned that might be tried?

C. F. Watts, M.D., Williamsburg, Iowa.

Answer.—Hygienic measures should be continued. The diet should be restricted, no alcoholic beverages, coffee, tea, cocoa, chocolate or ice cream sodas being permitted. Patients should avoid fried food, hot bread, batter cakes and heavy desserts and should eat little meat and carbohydrates, many vegetables and fruits. They should eat slowly, chew thoroughly, and drink plenty of water. Constipation, if present, should be corrected. These measures, combined with persistent ultraviolet treatment (not exceeding a mild erythema dose) should succeed with most of the superficial cases. For the others, focal infection should be looked for and eradicated if possible. The affected parts should be scrubbed with soap, followed by hot towels for ten minutes, then cold water or an ice rub. Then the skin should be dried and an application of lotio alba fortified with 6 per cent resorcinol should be made. Some of the deep cases will yield only to x-rays. The use of gold sodium thiosulphate is not an approved method of treatment of acne vulgaris. It is in the experimental stage. It is a dangerous drug, causing severe, sometimes fatal, reactions, and its use is not justified in a noninfectious disease that can be cured by less dangerous measures.

Council on Medical Education and Hospitals

COMING EXAMINATIONS

American Board of Obstetrics and Gynecology: Written examinations will be held in nineteen cities of the United States and Canada, March 26. The general, oral and clinical examination will be held in New Orleans, May 10. Sec., Dr. Paul Titus, 1015 Highland Building, Pittsburgh.

Arizona: Phoenix, April 5-6. Sec., Dr. B. M. Berger, 12 N. Central Ave., Phoenix.

California: *Reciprocity.* Los Angeles and San Francisco, March 16. Sec., Dr. Charles B. Pinkham, 420 State Office Bldg., Sacramento.

Colorado: Denver, April 6-9. Sec., Dr. Wm. Whitridge Williams, 422 State Office Bldg., Denver.

Connecticut: *Endorsement.* Hartford, March 22. Sec., Dr. Thomas P. Murdock, 147 W. Main St., Meriden.

Idaho: Boise, April 5. Comm. of Law Enforcement, Hon. Emmitt Pfost, Boise.

Illinois: Chicago, April 12-14. Supt., Mr. Paul B. Johnson, Springfield.

Minnesota: *Basic Science.* Minneapolis, April 5-6. Sec., Dr. J. C. McKinley, 125 Millard Hall, University of Minnesota, Minneapolis. *Regular.* Minneapolis, April 19-21. Sec., Dr. E. J. Engberg, 524 Lowry Bldg., St. Paul.

Montana: Helena, April 5. Sec., Dr. S. A. Cooney, Power Block, Helena.

New Hampshire: Concord, March 10-11. Sec., Dr. Charles Duncan, Concord.

New Mexico: Santa Fe, April 11. Sec., Dr. P. G. Cornish, Jr., 221 W. Central Ave., Albuquerque.

Rhode Island: Providence, April 7-8. Dir., Dr. Lester A. Round, 319 State Office Building, Providence.

West Virginia: Charleston, March 22. Sec., Dr. W. T. Henshaw, Charleston.

Wisconsin: *Basic Science.* Madison, March 19. Sec., Prof. Robert N. Bauer, 3414 W. Wisconsin Ave., Milwaukee. *Reciprocity.* Milwaukee, April 6. Sec., Dr. Robert E. Flynn, 315 State Bank Bldg., LaCrosse.

PRELIMINARY REPORT OF SURVEY OF HOSPITALS FOR NERVOUS AND MENTAL PATIENTS IN THE UNITED STATES *

At the annual session of the American Medical Association held at Detroit in June, 1930, the House of Delegates, on the initiative of the Section on Nervous and Mental Diseases, adopted two resolutions relative to the care of patients suffering from nervous and mental diseases. One directed the Trustees to appoint a special Committee on Mental Hygiene. The other directed the Council on Medical Education and Hospitals to make an "investigation of all hospitals caring for mental patients within the next one or two years," in order to obtain "a more accurate knowledge of the situation," and to point out "the need of further developments."

The language of this second resolution describes a task intentionally limited as to time and scope, and preparatory to a larger work whose exact nature the preliminary task would help to determine. No such limits were imposed on the Trustees' Committee on Mental Hygiene, nor was there stated or implied any relationship between the functions of this committee and those of the Council. Four months later, the Council itself requested the Trustees' committee to "serve as an advisory committee to the Council," and, as a result of this action of the Council, the committee has come to be known as the Advisory Committee.

The five men composing the Advisory Committee are all Fellows of the American Medical Association, all well known psychiatrists, and all active participants in the affairs of organized psychiatry and mental hygiene. By virtue of their positions, they represent unofficially the three groups of federal, state and private mental hospitals, and also the private office practitioners, the clinical psychiatrists, and the medical schools. The Council's work in the mental hospital field has been planned and is being carried out in as close association with this committee as possible. At the same time the essential coordination of this work with the other work of the Council has not been forgotten.

In the gathering of information, in all the Council's work with hospitals during the quarter century of its existence, two major procedures have stood the tests of time and accuracy: the questionnaire and the personal visit. The specific task of this report is to make known the results thus far obtained by the use of these two methods.

THE QUESTIONNAIRES

The work was definitely begun, Jan. 1, 1931. In consultation with the Advisory Committee, a questionnaire was prepared and mailed to the 561 institutions for nervous and mental patients listed in the Register of Hospitals. Of the 561 institutions, 416 have returned these questionnaires with the data asked for. While returns from seventeen states are already complete and those from the entire group are approximately 75 per cent complete, the questionnaires are still coming in and a more complete report will be possible at a later date.

In twenty-two states all the government-owned institutions addressed have returned the questionnaires; in each of twelve other states only one hospital has failed, and in each of an additional nine states only two hospitals have failed. That is, in forty-three of the forty-nine states (including the District of Columbia) all the federal, state, county and city mental hospitals except thirty have already returned the questionnaires, and many of these thirty hospitals will return them later. There are six states remaining to be accounted for. In four of these the returns have been between 75 and 80 per cent complete; in the other two the returns are now between 10 and 20 per cent complete.

In twenty-five states, all the private institutions have returned the questionnaires; in each of eight other states only one hospital has failed, and in each of an additional seven states only two hospitals have failed. That is, in forty states all private institutions have made returns except twenty-two, and we know that some of these will respond later. There remain nine states to be accounted for. In all of these the returns to date are between 50 and 75 per cent complete.

THE PERSONAL VISITS

Of the 561 institutions, personal visits have been made to 353. The conditions observed by the visitors can be reported more satisfactorily later, but a few general statements can be made now.

Of the government-owned group, the Veterans' Administration hospitals are on the whole comparatively new and well equipped, have relatively large medical staffs, and apparently give the individual patient good custodial and therapeutic care. Among county and city institutions, the great majority of those visited were found to be custodial in nature without any aspirations to the rank of hospitals. They are usually managed by laymen who are apparently intelligent and humane, interested in their work and carrying it on in a reasonably acceptable manner. The question whether or not these insane asylums, frankly divorced from considerations of therapy, have a rightful place in a modern mental health program is too complicated to be considered in this brief report.

In state hospitals, which are nearly three times as numerous as all federal, county and city institutions, personal contact with administrative heads revealed that overcrowding was almost universal. In several places it had been carried to a most deplorable extreme. Recreation rooms, living rooms and dining rooms had been made into dormitories. Beds had been placed on porches, in hallways, in attics and in basements. The lack of room was in some instances such as to rule out almost all classification on a basis of diagnosis or therapy, the only workable classification being on the basis of temperament; and without proper classification adequate care is impossible.

In several of these state hospitals there were no hospital units, the word hospital being applicable to them only in the broadest sense of the term. Others had no separate receiving units. Some lacked the equipment for giving patients proper diagnostic or therapeutic care. The personnel in many was admittedly inadequate, attendants being both too few and too incapable, and the medical staff being greatly undermanned. In the presence of such conditions no special knowledge or training was required for their discovery; indeed, if it had been required, many of the superintendents made it unnecessary by themselves calling the visitor's special attention to the conditions; the superintendents desired that such conditions be reported, in the hope that such a report might lead to their improvement.

---

* Read before the Annual Congress on Medical Education, Medical Licensure and Hospitals, Chicago, Feb. 15, 1932.

Private institutions fall easily into two classes: the sanatoriums and the rest homes (sanatoriums being interpreted as places for therapeutic care while rest homes are merely custodial). Nearly all sanatoriums were found clean, orderly, and apparently well conducted. They return a comparatively large percentage of their patients to active civil life, and they apparently merit the respect and support of the medical profession. While many rest homes meet a real need in a satisfactory way, several others have no adequate medical supervision and their value as medical institutions is nebulous.

The language here employed is not intended to convey the impression that the Council's visitors are sitting in judgment over these institutions. No such purpose is associated with this preliminary survey, and the language of this report describes the kind and amount of work done rather than its quality. The use of the data returned by these visitors as a basis for the rating of institutions for mental patients is an idea that has no place whatever in the program now being carried out.

It would be hard to overemphasize the value of the personal medical contacts that these visits to institutions have made possible. While personal visits have for years been included in the Council's work with hospitals both general and special, in no other group of hospitals has the need of such personal contacts been so evident or the immediate results so gratifying. Visits have necessarily been brief, but the danger of inaccuracies in reports is minimized by the use of the questionnaire, on which a superintendent makes his own report in writing, the superintendent's report and the visitor's report being checked against each other.

Little more need be said now regarding this unfinished task. With 353 visits made, there are some 200 more to be made. With 416 questionnaires already returned, 150 more are still to come in. The data thus secured must then be analyzed and interpreted. This study will be most carefully made, utilizing all the resources at our command. A final report will then be made to the House of Delegates.

New Mexico October Report

Dr. P. G. Cornish, Jr., secretary, New Mexico Board of Medical Examiners, reports 22 physicians licensed by endorsement, Oct. 12, 1931. The following colleges were represented:

College — LICENSED BY ENDORSEMENT	Year Grad.	Endorsement of
Birmingham Medical College, Alabama	(1914)	Alabama
Chicago College of Medicine and Surgery	(1917)	Illinois
Chicago Medical School	(1930)	Illinois
Rush Medical College	(1915)	Maryland
University of Illinois College of [illegible]	[illegible]	Illinois
Tulane University of Louisiana [illegible]	[illegible]	Texas
Tulane Unversity of Louisiana [illegible]	[illegible]	New York
Baltimore Medical College	[illegible]	Washington
Kansas City Hahnemann Medical College, Missouri	(1914)	Kansas
University of Nebraska Coll. of Med.	(1930)	Nebraska, Washington
National Normal University College of Med., Ohio	(1896)	Texas
Vanderbilt University School [illegible]	[illegible]	Texas

University of Texas School of Medicine	(1911), (1918)	Texas
Univ. of Lausanne Faculty of Med., Switzerland	(1921)*	New York

* Verification of graduation in process.

California October Report

Dr. Charles B. Pinkham, secretary, California Board of Medical Examiners, reports the written examination held at Sacramento, Oct. 20-22, 1931. The examination covered 9 subjects and included 90 questions. An average of 75 per cent was required to pass. Forty-five candidates were examined, 41 of whom passed and 4 failed. The following colleges were represented:

College — PASSED	Year Grad.	Number Passed
College of Medical [illegible]	[illegible]	5
Stanford University [illegible]	[illegible]	4
University of Colora [illegible]	[illegible]	3

University of Illinois College of Medicine	(1931)	1
Kentucky University Medical Department	(1904)	1
Washington University School of Medicine	(1929)	1
Univ. of Bordeaux Faculty of Med. and Pharmacy	(1930)*	1

Dr. Pinkham also reports 3 physicians licensed by endorsement of credentials in October, 1931. The following colleges were represented:

College — LICENSED BY ENDORSEMENT	Year Grad.	Endorsement of
Jefferson Medical College of Philadelphia	(1913), (1923)	U. S. Army
Medical College of Virginia	(1914)	U. S. Navy

* *Verification of graduation in process.*

Michigan October Examination

Dr. Nelson McLaughlin, secretary, Michigan Board of Registration in Medicine, reports the written examination held at Lansing, Oct. 13-15, 1931. The examination covered 14 subjects and included 100 questions. An average of 75 per cent was required to pass. Six candidates were examined, all of whom passed. The following colleges were represented:

College — PASSED	Year Grad.	Per Cent
Northwestern University Medical School	(1931)*	83.7
Johns Hopkins University School of Medicine	*(1929)*	83.8
Michigan College of Medicine and Surgery	(1891)	79
Hahnemann Med. College and Hosp. of Philadelphia	(1931)	83.3
Marquette University School of Medicine	(1931)*	83.7
University of Toronto Faculty of Medicine	(1930)	86.2

Dr. McLaughlin also reports 24 physicians licensed by endorsement from *Aug. 18 to Dec. 18, 1931. The following* colleges were represented:

College — LICENSED BY ENDORSEMENT	Year Grad.	Endorsement of
College of Medical Evangelists	(1931)	California, Oregon
Howard University School of Medicine	(1930, 2)	Maryland
Chicago College of Medicine and Surgery	(1917)	Illinois
[illegible] l of Medicine	(1930)	Illinois
[illegible] Medical School	(1931)	Illinois
[illegible] Woman's Medical School	(1897)	Illinois
Rush Medical College	(1928) Colorado, (1929), (1931)	Illinois
University of Illinois College of Medicine	(1926)	Illinois
Indiana University School of Medicine	(1930)	Indiana
State University of Iowa College of Med.	(1929), (1930)	Iowa
University of Kansas School of Medicine	*(1906)*, (1929)	Kansas
Detroit College of Medicine	(1897)	Illinois
Creighton University School of Medicine	(1927)	Nebraska
University of Nebraska College of Med.	(1920), (1923)	Nebraska
Hahnemann Med. College and Hosp. of Philadelphia	(1930)	Penna.
Meharry Medical College	(1929)	Tennessee
Baylor University College of Medicine	(1928)	Texas

* These applicants will receive their M.D. degrees on completion of an internship.

Iowa October Examination

Mr. H. W. Grefe, director, Iowa State Board of Medical Examiners, reports the written examination held at Des Moines, Oct. 20-22, 1931. The examination covered 8 subjects and included 100 questions. An average of 75 per cent was required to pass. Eleven candidates were examined, all of whom passed. Five physicians were licensed by reciprocity in December, 1931. The following colleges were represented:

College — PASSED	Year Grad.	Per Cent
Loyola University School of Medicine	(1931)	91.5,* 92,* 95.6*
Rush Medical College	(1931)	86.9
Sioux City College of [illegible]	[illegible]	75.5
College of Physicians [illegible]	[illegible]	92
[illegible]	[illegible]	94.8†
[illegible]	[illegible]	90.4
[illegible]	[illegible]	91.4
[illegible]	[illegible]	75.5
[illegible]	[illegible]	83.3

College — LICENSED BY RECIPROCITY	Year Grad.	Reciprocity with
Rush Medical College	(1927) Ohio, (1931)	Illinois
University of [illegible]	[illegible]	Illinois
University of [illegible]	[illegible]	Nebraska

* The M.D. degrees and licenses of these applicants are being withheld [illegible] of an internship.

† [illegible] pending completion of an internship.

‡ [illegible] in process.

Book Notices

Electrotherapy and the Elements of Light Therapy. By Richard Kovács, M.D., Clinical Professor and Director of Physical Therapy, Polyclinic Medical School and Hospital, New York. Cloth. Price, $6.50. Pp. 528, with 211 illustrations. Philadelphia: Lea & Febiger, 1932.

Among the pioneers in the promotion of electrotherapy in the United States is the author of this contribution. The material in the book is the basis of the courses of instruction in this subject given in the extension School of Medicine of Columbia University. The book begins with elementary electrophysics and proceeds from this theoretical basis to the technic of application, indications and contraindications of electrotherapy in various conditions. Like other writers, the author has been disturbed by lack of standardization in nomenclature, apparatus and similar factors to which the Council on Physical Therapy of the American Medical Association has given attention.

The book is divided into four parts—electrophysics, general electrotherapy and diagnosis, the elements of light therapy and applied electrotherapy. In the last mentioned section the use of electrotherapy in dermatology is discussed by Dr. J. J. Eller and its use in diseases of the ear, nose and throat by Dr. Wallace Morrison. The volume is certainly the most systematic contribution on the subject thus far available. It is orderly in arrangement, succinct and sound. It will be useful to practitioners in every field of medicine who avail themselves of the electrical forces, since it explains the apparatus used and the manner of use. It is an intensely practical book and quite up to date. Of special value is the section on electrodiagnosis with excellent tables of motor nerves and muscles which will be of aid to the neurologist and the diagnostician in whose practice electrodiagnostic tests may be frequently employed.

In the section on high frequency and diathermy, Dr. Kovács is again careful to avoid exaggeration and to indicate pointedly the limitations of this method. If there is any one section of the book with which disagreement may develop, it is that having to do with the use of static modalities. In this field there has always been difficulty in separating actual facts from those achieved by the power of suggestion.

The book may be recommended as a scientific contribution of great merit in a field in which there has been much unfortunate exploitation.

The Standard Metabolism of Boys (7 to 18 Years Inclusive). By Einar Bierring. Paper. Pp. 150, with illustrations. Copenhagen: Levin & Munksgaard, 1931.

This presents an extensive investigation involving about 1,000 experiments of the metabolism of 133 male subjects from 7 to 18 years of age. Bierring attempts to determine whether or not children are suited, under the present types of experimental control, for experiments in metabolism and also to throw light on the problem of the general trend of the metabolism during growth.

The study contains a review of the more significant investigations of standard metabolism (defined as the heat production of the fasting and reposing individual) of males under 18 years of age. A comparison of the standard values for the standard metabolism of normal boys, as reported by Du Bois (1917), Benedict and Talbot (1921), Cameron (1925), Bailey (1926), and Boothby and Sandiford (1929), led the author to conclude that "each standard must be considered an isolated whole typical only for the experimental conditions on which it is based." A summary of the experimental work done on the standard metabolism of boys leads to the statement that "the total heat production increases with age, height, weight, and surface area, whereas the heat production per unit of weight and surface area decreases during the interval considered (7-18 years)." The evidence concerning the increase in relative heat production at different periods of growth, e. g., at puberty, is not conclusive.

From a study of the constancy of respiratory quotients in normal healthy boys, the reliability of determinations of surface area by well known formulas and the coefficients of variability of single experimental series and the individual variability of whole series, Bierring concludes that metabolism experiments with boys from 7 to 18 years of age should be of as much clinical value as corresponding experiments with adults. He finds that the total heat production increases with increasing age, weight, height, and surface area. Relative heat production shows a nearly straight-line decrease with increasing age. There is no evidence of an increase in average heat production at the interval 7 to 13 years as found by Kestner and Knipping, at 12 to 13 years as reported by Du Bois, or at the period of puberty (Göttche, Lax and Petenyi). An individual increase in metabolism is found in a group of boys 14 years old and in a few boys 15 years of age (all manifesting signs of puberty) but in no case is the increase more than 13 per cent. Standard values of the standard metabolism of boys from 7 to 18 years of age are given in two tables expressed in terms of total calories referred to weight and calories per square meter, referred to age. The quantitative treatment of the data is thorough and sound. The presentation is scholarly.

Lane Lectures on Pharmacology. By Walther Straub, M.D., Ph.D., Professor of Pharmacology, University of Munich. Stanford University Publications, University Series, Medical Sciences, Volume III, No. 1. Paper. Price, $1. Pp. 87, with 9 illustrations. Stanford University: Stanford University Press, 1931.

The Lane lectures in this monograph were delivered by Professor Straub in April, 1929. A considerable range of subjects was covered: intoxicating drugs, ways to ideal anesthesia, chemistry and biochemistry of digitalis, general pharmacology of heavy metals, and camphor and the modern analeptics. The first lecture contains matters of general and popular interest based on much scientific and historical data, which are interpreted and correlated in interesting ways. The remaining five lectures give the results of the author's researches in experimental pharmacology. Straub's studies on digitalis naturally make his two lectures on this subject the choicest portion of the monograph. The lecture on heavy metals deals with fundamentals in the actions of these agents, including original work on chronic lead poisoning and some new work on the selective localization of uranium. The lecture on anesthesia recognizes the achievement of America in this field and gives a cross-section of the actions of the different types of anesthetic agents, including agents proposed for intravenous anesthesia, such as the barbitals and "Avertin." The lecture on camphor has two purposes: first, the illustration of the German method of instruction, that is, the lecture interspersed with demonstrations, and, second, the unfolding of a scientific problem, which in the particular case is an empiric drug (camphor) with a particular attribute, which is developed into desirable and practical substitutes, with the aid of chemical synthesis and pharmacologic analysis. Throughout these lectures the author easily lives up to a well earned reputation as a master of experimental investigation, who not only has original ideas and uses ingenious experimental devices but also knows how to hold the attention of his audience. In making good use of chemistry and in giving it due credit, and in creating new and useful drugs, Straub readily points out that the final and complete development is achieved pharmacodynamically. In a concluding phrase he tritely remarks, "chemistry experiments and pharmacology investigates." Straub's lectures should prove interesting and profitable reading for practitioners, medical students, teachers and investigators.

Rheumatoid Arthritis and Its Treatment: Studies from the Royal Mineral Water Hospital, Bath. By Vincent Coates, M.C., M.A., M.D., Consulting Physician, Trowbridge and District Hospital, and Leo Delicati, L.M.S.S.A., Resident Medical Officer, Royal Mineral Water Hospital, Bath. Cloth. Price, 6s. Pp. 114, with 12 illustrations. London: H. K. Lewis & Company, Ltd., 1931.

This little book is dedicated to the International League against Rheumatism. The material is based on the studies made at the Royal Mineral Water Hospital, Bath, England. The majority of patients are from the lowest economic level of society. The manual is an attempt to deal almost exclusively with the systemic and local treatments of rheumatoid arthritis, especially in regard to the prevention of contractures. The observations cover a period of several years, but for statistical purposes 100 consecutive cases of rheumatoid arthritis were considered. The book is written entirely from a therapeutic point of view. The authors outline the classification of joint diseases and give a description of the clinical picture of rheumatoid arthritis. Their classification includes infectious arthritis, metabolic arthritis, degenerative arthritis, mixed arthritis, and neuropathic arthritis. They give also a list of the deformities that may occur in the various regions of the body. The writers believe that streptococcal vaccines given over a long period in doses carefully graduated to avoid reaction are helpful when streptococcal immunity is lowered. Sometimes staphylococcal vaccine is useful. Approximation of joint surfaces should be forbidden to any weight bearing joint, in the early inflammatory stage, except in a deep bath. Relaxation in a hot bath is the simplest method of getting a full joint movement daily which is to prevent organization of minute cobweb adhesions. This one full movement of each joint daily should be carried out when the patient is in a relaxed position. Gentle movements and daily massage obviate contracture at the knee. The authors found that local dressings and blisters are the two most useful remedies for the reduction of swelling with heat and wintergreen most useful for the reduction of pain, although a simple application of iodine is often efficacious. A joint should be assessed by the function it is capable of performing and not by its pathologic shortcomings. A roentgenogram is no criterion of the function a joint is capable of performing. Twenty-six case histories are given.

Modern Proctology. By Marion C. Pruitt, M.D., L.R.C.P., F.R.C.S., Associate in Surgery, Emory University School of Medicine. Cloth. Price, $8. Pp. 404, with 233 illustrations. St. Louis: C. V. Mosby Company, 1931.

One wonders why every writer of a new book speaks of proctology as a neglected field. It seems that there are countless books written on this limited subject. With few exceptions, little new has been added. The author devotes considerable space to the anatomy of the rectal area and to methods of examination, and one chapter to a description of methods of anesthesia. In general, the subject matter dealing with diseases of the anus and rectum is well presented. One might ffer with the author in advising retention oil enemas of 10 es instead of much less or in prescribing liquid petrolatum mild purgations to establish regulation of evacuations. o mention is made of the possible rôle of allergy in causation of pruritus ani and of mucous colitis. How much benefit can the oral administration of 0.65 Gm. of bismuth subnitrate or 0.3 Gm. of phenyl salicylate or sulphonated bitumen have in overcoming intestinal fermentation? One cannot become enthusiastic over the descriptions of diseases of the colon as mucous colitis, ulcerative colitis and diverticulitis. They are for from being complete. The sections dealing with operative technic are good. More stress should be laid on postoperative care. There is a profusion of excellent illustrations and the bibliography is extensive.

Arbeitsmedizinische Studien in Nord-Amerika und Süd-Afrika. Von Dr. Franz Koelsch, Professor an der Universität und an der Technischen Hochschule in München. Schriften aus dem Gesamtgebiet der Gewerbehygiene, Heft 37. Herausgegeben von der Deutschen Gesellschaft für Gewerbehygiene in Frankfurt a. M. Paper. Price, 14.50 marks. Pp. 210. Berlin: Julius Springer, 1931.

This is an account of the tour of a German industrial hygienist through portions of the United States and South Africa, visiting some of the principal industrial medical organizations and the persons in charge. The author says in the introduction:

> From the very beginning my interest and endeavors were not limited strictly to the hard and fast question of industrial medicine but included the social and humanitarian interests of the working man in general—his social level, his place in community life, the bearing that conditions in the shop and the wages paid, have on his life and mode of living, the insurance and welfare problem, etc. As all these social aspects involve one another, and to understand them it is necessary to know the particular function of each, so we must first investigate the organized labor conditions of the land in each instance.

Sections are devoted to the lands and peoples visited, their respective wealth and castes, their morale, wages and standards of living, extent of cooperation between the employers and employees, labor organization, opportunities, and the problem of home work, the old worker, the unemployed, employment insurance and welfare, types of plants, quality of fittings and equipment, plant hygiene, welfare of workers, the use of physiology and psychology in proper job placement, the services of the industrial physician, accidents and their prevention, mining, plant executives and plant supervision, medical facilities, the food of the worker in relation to his job, prohibition, organization of program and travel, Johannesburg, gold mining together with its social and hygienic achievements and the labor questions it involves, the problem of silicosis, the organization and function of medical organizations, South Africa and its people, the color question, the caste question, and the general social outlook. To persons in this country the booklet is of worth as an appraisal of industrial medicine in large industries by a well qualified outsider who is familiar with the activities of this type in other countries. Primarily it is designed to furnish information to German physicians and industrial hygienists on industrial medical, hygienic and social conditions in the United States and South Africa.

The Papyrus Ebers. Translated from the German Version. By Cyril P. Bryan, M.B., B.Ch., B.A.O., Demonstrator in Anatomy, University College, London. With an introduction by Professor G. Elliot Smith, M.D., D.Sc., Litt.D., Professor of Anatomy, University College, London. Cloth. Price, $3. Pp. 167, with 16 illustrations. New York: D. Appleton & Company, 1931.

Until the discovery of the Edwin Smith papyrus, the papyrus Ebers was considered the most important ancient medical document available. The new discoveries have not in any way replaced the interest in the Ebers papyrus; rather, they have intensified it. Many years ago an attempt was made to translate the Ebers papyrus into German. The present document offers not a complete translation but rather a popularization of the interesting information available in the document. It is essentially a guide to the materia medica and therapy of the period of about 1500 B. C.

Enfermedades de los viejos. Por Carlos Diez Fernandez, del Hospital Nacional de Enfermedades Infecciosas de Madrid. Nociones para el medico practico. Paper. Price, 6 pesetas. Pp. 232. Madrid: Javier Morata, 1931.

This is a clinical survey of diseases of old age. Pulmonary tuberculosis is more frequent than might be supposed and occurs oftener in women than in men; bronchopneumonia as a sequel to various debilitating conditions is fully described; the gravity of erysipelas, septicemias and the common cold are stressed. Cerebral and circulatory disturbances from arteriosclerotic changes are adequately discussed. Malignant conditions, although frequent in older people, decrease in their incidence with increasing age.

A Doctor of the 1870's and 80's. By William Allen Pusey. Cloth. Price, $3. Pp. 153, with 28 illustrations. Springfield, Illinois: Charles C. Thomas, 1932.

Fortunate is the son to whom his father is a hero. Fortunate also is the father whose son can with sincere appreciation recount the record of his father's useful life. From memories, from diaries and with excellent photographs made by himself at the time, Dr. Pusey reconstructs the life of a doctor of the old school in the years from 1880 to the beginning of the present century. The book serves, incidentally, the purpose of recording systematically the qualities of the practitioner of that day which endeared him in general to all the people and which make modern man view with regrets the coming of the machine age in medicine. The book is replete with citations to letters and documents which bring the reader promptly into the proper atmosphere for understanding. Dr. Pusey has also been exceedingly fortunate in his publisher. The book seems to have been designed and published *con amore*.

Lehrbuch der Allgemeinen Physiologie. Herausgegeben von Dr. Phil. et Med. Ernst Gellhorn, a. o. Professor der Physiologie an der Universität Halle. Paper. Price, 47 marks. Pp. 741, with 126 illustrations. Leipzig: Georg Thieme, 1931.

As the title indicates, this volume is a textbook of general physiology designed for students interested in the field. Written from the point of view first expressed by Claude-Bernard, the author does a most creditable and systematic job. At the end of each chapter there is a comprehensive bibliography. In succeeding chapters one finds a discussion of the cell as a physicochemical system, chemistry of cell processes, energetics of the living substance, the cell as a morphologic system, general physiology of cell development and architecture, general physiology of irritable processes, and tropisms. The practicing physician will not find the book serviceable to him although the phenomena discussed are at the basis of, or tantamount with, life itself.

Annual Report of the Board of Regents of the Smithsonian Institution Showing the Operations, Expenditures, and Condition of the Institution for the Year Ending June 30, 1930. (Publication 3077). Cloth. Price, $2. Pp. 650, with illustrations. Washington, D. C.: Supt. of Doc., Government Printing Office, 1931.

Most governmental documents, particularly the reports of government bureaus, are dry and uninteresting contributions of statistical material. The Smithsonian Institution is an exception. It provides the usual material included in government reports but the general appendix includes lectures and essays by workers in the institution which are worthy of record and study. For instance, the report for 1930 includes an essay entitled "Beyond the Red in the Spectrum," another on the modern sun cult, one on the autogiro; another on gliding, several reports on the weather, one on man and insects, another on general entomology, and many on biologic topics. There are also discussions on anthropology and ethnology. The material is beautifully printed, fully and handsomely illustrated, and well worthy of permanent record.

Die gesamte Kosmetik (Entstellungsbekämpfung): Ein Grundriss für Ärzte und Studierende. Von Dr. Martin Gumpert, Facharzt für Hautkrankheiten in Berlin. Paper. Price, 12.80 marks. Pp. 228, with 45 illustrations. Leipzig: Georg Thieme, 1931.

For those who are of the opinion that dermatology as a branch of medicine is threatened with extinction and that the future dermatologist may become a cosmetician the present volume will prove of interest. The title chosen by Dr. Gumpert implies a broader conception of the subject, including the correction of cosmetic defects by operative procedures. There are chapters on the disfiguring skin diseases, on the technic of physical methods as applied in the cosmetic therapy of the skin, and a discussion of the varied medicinal agents used in the care of the normal and the diseased skin and its appendages. This book can be recommended as a sound, practical exposition of a phase of dermatology that is all too frequently left to the laity or to charlatans.

Medical Men in the American Revolution, 1775-1783. By Louis C. Duncan, Lieut. Colonel, U. S. Army, Retired. Paper. Pp. 414, with illustrations. Carlisle Barracks: Medical Field Service School, 1931.

A special issue of the *Army Medical Bulletin,* number 25, prepared by Lieut. Col. Louis C. Duncan, has just made available a complete account of medical men of the American Revolution. The *Bulletin* is a valuable contribution to American medical history. It indicates a vast amount of research and should be made available in permanent book form. The account is entertaining as well as instructive. It is supplemented by reprinting of numerous original documents, letters, official orders and reports, and includes many drawings and photographs assembled from various sources.

Osler and Other Papers. By William Sydney Thayer, M.D., LL.D. Cloth. Price, $3.50. Pp. 386. Baltimore: The Johns Hopkins Press; London: Humphrey Milford, Oxford University Press, 1931.

Dr. Thayer, for many years a leader in medicine in this country, recognized for his personality and his interests in the esthetic side of medical practice, has accumulated under one cover addresses delivered during many years. Five chapters of the book are devoted to intimate reminiscences of William Osler; others are biographic tributes to great figures, such as Fitz, Welch, Pasteur, Bright and Howland. A few of the essays deal with medical education, with the history of medicine and with the relationships of the physician to his profession and to the public. Dr. Thayer writes carefully, systematically and with a personal tone that is his own. His friends—and their number is legion—will appreciate the opportunity to have permanently this work, which is so much the man himself.

The Jungle of the Mind. By Edgar James Swift, Head of the Department of Psychology, Washington University, St. Louis. Cloth. Price, $2.50. Pp. 340. New York: Charles Scribner's Sons, 1931.

The mind of man is still much of a mystery. The great discoveries of science, themselves miraculous, merely confuse many of the public into believing that anything is possible and everything is credible. It has interested Professor Swift to consider the human mind as a jungle through which the path is only beginning to be found. His chapters on curiosities of the mind, on the will to believe, and on telepathy, memory and mental healing are amusing and instructive. He has collected his data from hundreds of sources and he illustrates each of his points with anecdote and case history. Into the midst of a vast amount of folly now being written on such subjects as behaviorism and psychoanalysis this book sweeps like a breath of fresh air. The book is exceedingly worth while as a contribution to rationalism and also as a contribution to philosophy. Furthermore, it will provide any reader several hours of extraordinarily good entertainment.

The Principles of the Prophylaxis of Leprosy. First General Report of the Leprosy Commission. League of Nations, Health Organisation. Series of League of Nations Publications, III. Health, 1931. III. 2. Official No.: C. H. 970. Paper. Price, 15 cents. Pp. 12. Geneva: League of Nations, 1931.

Prophylaxis of leprosy is not a problem that admits of solution by the application of any one measure but varies with geographic, economic, administrative, financial and social conditions. Treatment is an important part of prophylaxis, and the earlier this is instituted, the sooner the patient may become bacteriologically negative and clinically "cured." In countries where leprosy is prevalent, facilities should be available for clinics and dispensaries, scientific research and service for discharged lepers. There is a discussion of isolation and treatment and a plea for uniformity of terminology, records and technic of examination.

Midwifery. By Ten Teachers under the direction of Comyns Berkeley, M.A., M.D., M.C. Edited by Comyns Berkeley, J. S. Fairbairn and Clifford White. Fourth edition. Cloth. Price, $7.50. Pp. 740, with 301 illustrations. New York: William Wood & Company, 1931.

This book is simply written and is intended for students. It is written somewhat on the order of a manual, most phases of the subject being only briefly discussed. The book is divided into five sections, which include pregnancy, labor, the puerperium, the new-born child, and relief of pain and suffering in obstetric practice. A questionable procedure described under cesarean section is the delivery of the uterus onto the abdominal wall after the birth of the child. The sutures are put into the uterine wall with the uterus thus exposed. The illustrations are mostly diagrams and are instructive. Although written by ten contributors, the method of presentation is the same in all chapters, thus making the style appear individual. The book should be a valuable aid to the student preparing for examination or to the general practitioner needing a ready reference handbook on obstetrics.

Aversión y atracción en el matrimonio. Por el Dr. Th. H. Van de Velde. Traducción directa de la séptima edición alemana por José W. Nake, intérprete jurado de Madrid. Prólogo del Doctor José M. Sacristán. Paper. Pp. 354, with illustrations. Madrid: Javier Morata, 1931.

The Spanish translation of this German work is preceded by a few introductory remarks by Dr. José M. Sacristán. The educational value and the necessity of publications of such works as this by Van de Velde to the Spanish-speaking world are emphasized. The Spanish translation reads itself fluently and holds one's attention.

The Note-Book of Edward Jenner in the Possession of the Royal College of Physicians of London. With an Introduction on Jenner's Work as a Naturalist. By F. Dawtrey Drewitt, M.D., F.R.C.P. Cloth. Price, $1.25. Pp. 49. New York: Oxford University Press, 1931.

This volume is prefaced by a photogravure of Edward Jenner worthy of a place as an adornment in any medical office. The manuscript notebook of the great founder of modern immunology came into possession of the Royal College of Physicians in 1888. The manuscript consists of a notebook of eighty pages, some of which are blank. It covers the period from 1787 to 1806 and records observations made by Jenner concerning the habits of the cuckoo, the presence of hydatids in the bodies of various animals, and distemper in dogs. Edward Jenner was a naturalist as well as a physician. He made many necropsies on dogs that had died of distemper, his one important conclusion being that the lungs are often the seat of extensive inflammation. The book includes not only an exact transcription in good type of the contents of the book but also an appreciative essay by Dr. Drewitt. The reasonable price and the artistic character of this publication make it an inviting volume for any physician's personal collection.

Medicolegal

Liability of Charitable Hospital for Injury to Invitee

(Cohen v. General Hospital Soc. of Connecticut (Conn.), 154 Atl. 435)

The wife of the plaintiff, Cohen, was a patient in a hospital owned and operated by the defendant, the General Hospital Society of Connecticut. She had been discharged, and Cohen went to the hospital to take her home. While on the hospital premises he tripped over an iron pipe that had been negligently placed and permitted to remain near the exit from the hospital building. He brought suit for damages on account of the injuries that resulted from the fall. From a judgment in the trial court in favor of the hospital, he appealed to the Supreme Court of Errors of Connecticut.

The defendant, The General Hospital Society of Connecticut, was incorporated by a special act of the General Assembly of the state in 1826, for the purpose of establishing and maintaining a general hospital in New Haven. By way of defense, it claimed that it was a state institution performing governmental functions. Therefore, it argued, it was immune from liability, under the theory that limits the liability of a municipal corporation for acts done by it in the performance of a governmental duty. The act under which the corporation was organized, said the Supreme Court of Errors, created a private corporation dedicated to the purpose of general and public charity. While the corporation is a public charity in the popular significance of the term and the benefits it bestows are public, its organization and management are private. Though it receives aid from the state in the way of exemption from taxation and by state appropriation toward its support, it is not a state institution and in its operation is not acting as an agency of the sovereign. It is therefore not entitled to immunity on the ground that it is an arm of the government engaged in the performance of a public governmental duty.

The Hospital Society claimed further that as it was a charitable institution its funds were held in trust for the particular charitable purposes for which they were given, that payment of damages awarded in actions for injuries resulting from neglect or wrongful acts was not a purpose contemplated by the trust, and that it would be a breach of trust to apply the funds to the payment of such damages. But, said the court, the fact that the hospital's funds are held in trust does not free it from liability for its wrongful acts. Being a corporation organized for charitable purposes, it is bound to apply its corporate funds to charitable purposes only. It holds such funds under a quasi trust arising from that restriction. In this respect, however, it does not differ from any business corporation, whose officials are bound to hold and apply its property only for the purposes for which the corporation was organized. Such immunity from liability for its wrongful acts as may be claimed by a charitable corporation must be based, not on the public character of its charity, nor on the fact that its funds are held in trust, but on its eleemosynary character. It has been said that public policy forbids the crippling or destruction of charities established for the benefit of the whole public, to compensate one person for injuries suffered through the negligence of the corporation or of its servants or agents; that it is better that an individual should suffer injury without compensation than that the public be deprived of the benefit of the charity. *Vermillion* v. *Woman's College of Due West,* 104 S. C. 197, 88 S. E. 649. However that may be, in most jurisdictions charitable hospitals are held immune from liability to their patients for the negligence of the hospital's employees or agents, but they are subject to actions in tort by strangers or by their own employees, and their funds subject to depletion by the payment of damages awarded in such actions. This has not resulted in crippling or destroying such charitable institutions in jurisdictions in which this principle is adhered to.

If the enforcement of the right of individuals to recover from charitable corporations does not deprive the public of the benefits of such institutions, we fail to see, said the court, on what ground it can be said that public policy requires that a charitable corporation should be granted absolute immunity from liability for its neglect or wrongful acts. It is a corporation capable of suing and being sued and liable on its contracts as is any other person, corporate or individual. That its funds have been dedicated to charity does not place it beyond the law; the will of the donor or donors of the funds of the institution does not exempt them from the operation of the general laws of the land. A charity should not be permitted to inflict injury on some persons without the right of redress, in order to bestow charity on others. The result would be to compel the injured person to contribute to the charity against his will. The modern tendency of the law is, on the contrary, to shift the burden from the innocent victim to the community at large.

Whether or not, and to what extent, a charitable corporation is liable in tort for negligence is a question that has often vexed the courts. The cases on the subject present an almost hopelessly tangled mass of reason and unreason. In a number of states the courts have held such corporations entitled to an absolute exemption from tort liability to every class of plaintiff. In the better reasoned cases the courts have held such institutions liable in tort to strangers, invitees and employees, not discovering any sound reason of public policy justifying an exemption from liability. Here the plaintiff was not a patient of the hospital; he was at most an invitee, when he went to the hospital for his wife, who had been a patient. The fact that he had agreed to pay for her care and treatment at less than its cost to the defendant did not place him in the same legal situation as his wife had she been the plaintiff. The defendant owed him the duty which any land owner owes to an invitee who comes on his premises. For the reasons stated the judgment of the trial court was reversed and the case remanded for a new trial.

Malpractice: Care and Skill Required of Chiropractor.—Since a chiropractor is required by law in California to use the same degree of care, diligence and skill in the treatment of his patients as is used by other chiropractors, the district court of appeal, fourth district, California, refused to disturb a judgment in favor of a patient against a chiropractor where there was evidence in the record supporting a jury's finding that the chiropractor had not possessed nor exercised the care and skill possessed and used by other chiropractors in that vicinity and in consequence had broken or torn the cartilage connecting his patient's ninth right rib with the sternum.—*Howe v. McCoy (Calif.), 298 P. 530.*

Society Proceedings

COMING MEETINGS

Alabama, Medical Association of the State of, Mobile, April 19-22. Dr. D. L. Cannon, 519 Dexter Avenue, Montgomery, Secretary.
American Association for Thoracic Surgery, Ann Arbor, Mich., April 18-20. Dr. Duff S. Allen, 3720 Washington Blvd., St. Louis, Sec'y.
American Association of Anatomists, New York, March 24-26. Dr. George W. Corner, University of Rochester School of Medicine, Rochester, N. Y., Secretary.
American Association of Pathologists and Bacteriologists, Philadelphia, April 28-29. Dr. Howard T. Karsner, 2085 Adelbert Road, Cleveland, Secretary.
American Association of Physical Anthropologists, Washington, D. C., March 21-23. Dr. D. J. Morton, 632 W. 168th St., New York, Sec'y.
American College of Physicians, San Francisco, April 4-8. Mr. E. R. Loveland, 133 South 36th Street, Philadelphia, Executive Secretary.
American Physiological Society, [illegible] r. Arno B. Luckhardt, 5216 Greenwood [illegible]
American Society for Experime [illegible] April 28-30. Dr. C. Phillip Miller, Jr., U [illegible] Secretary.
American Society for Pharmacology and Experimental Therapeutics, Philadelphia, April 27-30. Dr. V. E. Henderson, University of Toronto, Toronto, Secretary.
American Society of Biological Chemistry, Philadelphia, April 28-30. Dr. H. B. Lewis, University of Michigan Medical School, Ann Arbor, Secretary.
Arizona State Medical Association, Globe, April 21-23. Dr. D. F. Harbridge, 407 Goodrich Building, Phoenix, Secretary.
Arkansas Medical Society, Little Rock, April 5-7. Dr. William R. Bathurst, 814 Boyle Building, Little Rock, Secretary.
Maryland, Medical and Chirurgical Faculty of, Baltimore, April 26-27. Dr. Walter Dent Wise, 1211 Cathedral Street, Baltimore, Secretary.
Medical Society of the Missouri Valley, Omaha, Neb., March 29-31. Dr. Joseph D. McCarthy, 107 South 17th Street, Omaha, Secretary.
Mississippi State Medical Association, Jackson, April 12-14. Dr. T. M. Dye, Clarksdale, Secretary.
North Carolina, Medical Society of the State of, Winston-Salem, April 18-20. Dr. L. B. McBrayer, Southern Pines, Secretary.
South Carolina Medical Association, Columbia, April 19-21. Dr. E. A. Hines, Seneca, Secretary.
Southeastern Surgical Congress, Birmingham, Ala., March 7-8. Dr. B. T. Beasley, 45 Edgewood Avenue, Atlanta, Ga., Secretary.
Tennessee State Medical Association, Memphis, April 12-14. Dr. H. H. Shoulders, *706 Church Street, Nashville, Secretary.*

Current Medical Literature

AMERICAN

The Association library lends periodicals to Fellows of the Association and to individual subscribers to The Journal in continental United States and Canada for a period of three days. Issues of periodicals are kept on file for a period of five years only. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 12 cents if two periodicals are requested). Periodicals published by the American Medical Association are not available for lending, but may be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

Alabama Medical Association Journal, Montgomery

1: 233-272 (Dec.) 1931

Treatment of Fibroid Tumors of Uterus: Analysis of 318 Cases. W. C. Dixon, Nashville, Tenn.—p. 233.
Pellagra. W. D. Partlow, Tuscaloosa.—p. 237.
Childhood Type of Tuberculosis. P. W. Auston, Montgomery.—p. 238.
Early Diagnosis of Pulmonary Tuberculosis. T. D. Rivers, Montgomery.—p. 242.
Home Treatment of Pulmonary Tuberculosis. S. B. McPheeters, Montgomery.—p. 245.
Artificial Pneumothorax in Treatment of Pulmonary Tuberculosis. N. R. Clarke, Jr., Mobile.—p. 250.
Tuberculosis of Kidney: Report of Cases. C. A. Grote, Huntsville.—p. 259.

American Heart Journal, St. Louis

7: 133-278 (Dec.) 1931

*Congenital Medial Sclerosis of Coronary Artery. R. W. Kissane, Columbus, Ohio, and R. S. Fidler, Springfield, Ohio.—p. 133.
*Rheumatic Heart Disease: I. Incidence and Rôle in Causation of Death: Study of Five Thousand Two Hundred and Fifteen Consecutive Necropsies. D. Davis and Soma Weiss, Boston.—p. 146.
*Studies in Congestive Heart Failure: XVI. Clinical Value of Ventilation Test in Estimation of Cardiac Function. T. R. Harrison, S. Harris, Jr., and J. A. Calhoun, *with assistance of* M. M. Tims, Nashville, Tenn.—p. 157.
*Depression of Vomiting Reflex by Digitalis Bodies. H. Gold, Janet Travell and N. Kwit, New York.—p. 165.
Eosinophilia Due to Administration of Digitalis. A. E. Smith and S. R. Benner, St. Louis.—p. 182.
Observations on Duration of Electrical Systole of Heart, with Especial Reference to Effect of Digitalis. K. Berliner, New York.—p. 189.
Accuracy of Einthoven's Equation. F. N. Wilson, A. G. MacLeod and P. S. Barker, Ann Arbor, Mich.—p. 203.
*Potential Variations Produced by Heart Beat at Apexes of Einthoven's Triangle. F. N. Wilson, A. G. MacLeod and P. S. Barker, Ann Arbor, Mich.—p. 207.
Localized Pleural Effusion in Heart Failure: Two Cases. J. M. Steele, New York.—p. 212.
Incidence of Heart Disease and Etiologic Types in Southern Dispensary. E. H. Schwab and V. E. Schulze, Galveston, Texas.—p. 223.
Large Q-Wave of Electrocardiogram: Correlation with Pathologic Observations. N. M. Fenichel and V. H. Kugell, New York.—p. 235.
Nature of Experimental Flutter and Fibrillation of Heart. W. A. Brams and L. N. Katz, Chicago.—p. 249.
Congenital Heart Disease: Clinical and Pathologic Study of Two Cases of Truncus Solitarius Aorticus (Pulmonary Atresia). M. A. Kugel, New York.—p. 262.

Congenital Medial Sclerosis of Coronary Artery.—Kissane and Fidler report a case of congenital medial sclerosis of the coronary arteries and present a review of the literature. The process is noninflammatory and is characterized by a primary medial thickening, confined to the larger coronary branches. The process is probably an earlier stage than those previously reported. The electrocardiogram shows a T-wave similar to that seen in the more familiar types of coronary sclerosis. The authors suggest the name of congenital medial sclerosis of the coronary arteries.

Rheumatic Heart Disease.—Davis and Weiss state that, among the 5,215 consecutive necropsy examinations of patients from the poorer class who were cared for in the Boston City Hospital between the years 1905 and 1929 inclusive, a combined clinical and morphologic study revealed rheumatic heart disease in 474, or 9.1 per cent, of the cases. Rheumatic heart disease was found in 56.6 per cent of the males, and in 43.4 per cent of the females in the group with rheumatic heart disease. The sex distribution in the total necropsy examinations was: males, 62 per cent; females, 38 per cent. Thus rheumatic heart disease was slightly more prevalent among the females. Eighteen, or 3.8 per cent, of the total number with rheumatic heart disease were Negroes. Eight per cent of the patients examined post mortem were Negroes. This would indicate that rheumatic heart disease occurs only about half as frequently among Negroes living in New England as among the white race. Rheumatic heart disease was directly responsible for death in 164 instances, or 34.5 per cent, of the total group with rheumatic heart disease. In an additional group of forty-one cases, corresponding to 8.6 per cent of all the cases in this group, subacute bacterial endocarditis was superimposed on rheumatic disease. In twenty-one cases, corresponding to 4.4 per cent of these cases, malignant endocarditis developed in association with rheumatic heart disease. In two additional cases, secondary malignant endocarditis was independent of the rheumatic heart disease. As the subacute and primary acute endocarditis developed on previously damaged rheumatic valves, in this group, representing 13 per cent of all cases of rheumatic heart disease, death was caused indirectly by rheumatic heart disease. Rheumatic heart disease contributed to death in forty-one instances, or 8.6 per cent, of the total cases. In 205 cases, or 43.2 per cent of the cases of rheumatic heart disease, the character of the cardiac involvement was such that the lesions did not contribute to death. Rheumatic heart disease is surprisingly prevalent among the poorer section of the population of Boston. Its frequency (9.1 per cent) approaches that of carcinoma (10.4 per cent). Rheumatic heart disease frequently exists as a mild "forme fruste" manifestation, without causing obvious impairment of the circulation.

Congestive Heart Failure.—Measurements of the vital capacity and of the ventilation on the performance of a series of standardized exercises were made by Harrison and his associates on 100 subjects. Of these, twenty-one were normal, sixteen had cardiac neurosis, ten had organic cardiac disease without symptoms, twenty-one had dyspnea on exertion only, and thirty-two had, in addition to dyspnea on exertion, some respiratory discomfort at rest. From the measurements a value called the ventilation index, which is a fairly close objective expression of the degree of dyspnea, was calculated. Analysis of the data shows that the determination of the ventilation index is of little or no value in the diagnosis of the presence or absence of organic heart disease, because patients with cardiac neurosis, patients with asymptomatic cardiac disease and normal subjects all occasionally have borderline tests, although the majority of patients in these groups have normal values. Patients with cardiac dyspnea nearly always have high values for the ventilation index but in such patients the customary methods of study are usually adequate to establish a diagnosis of the presence of organic cardiac disease. In a given case repeated determinations of the ventilation index may be of considerable value in prognosis. Single tests give relatively little information as to the outlook. In general, the patients with low values have a good prognosis and those with very high values have a poor outlook but exceptions are fairly numerous because the test measures only the degree of dyspnea at the moment and is not influenced by such extremely important factors as the liability to infection, the tendency to thrombosis or the likelihood of coronary and other vascular accidents. The ventilation test appears to be of definite clinical value in one group of cases: namely, in those patients who have both organic and functional disorders referable to the heart. Such instances are not uncommon and the ventilation test allows one to determine with fair accuracy how much of the patient's dyspnea is due to the cardiac neurosis and how much to the cardiac disease. This information, which cannot be obtained by any other method, may be of considerable value in prognosis and in treatment. The authors believe that the chief value of the ventilation test is in research, because it provides a method for determining quantitatively the effect of various therapeutic measures on dyspnea.

Depression of Vomiting Reflex by Digitalis Bodies.—Gold and his associates describe experiments in which they noted that repeated doses of the digitalis bodies may depress the vomiting reflex while simultaneously increasing the intensity of the cardiac poisoning, so that after an initial period of vomiting the continued administration of these drugs may fail to produce emesis and may even cause death without further vomiting. These experimental results suggest the need of caution in relying on nausea and vomiting as measures of the degree of cardiac poisoning in the clinical use of the digitalis bodies.

Einthoven's Triangle.—Wilson and his associates describe a method by means of which it is possible to determine the potential variations produced by the heart beat at any one or all of the apexes of Einthoven's equilateral triangle. It is consequently possible to determine the potential variations produced by the heart beat at any point of the body by leading from this point to the left leg, or the left or right arm, and subtracting the effect produced by the potential variations of this extremity from the recorded curve. It is possible by this method to free curves obtained by leading from points on or near the heart to points at a distance, such as on the left leg, from the influence exerted by potential variations at the distant electrode.

Study of Yellow Fever by Protection Test in Mice. F. F. Russell, New York.—p. 87.
Presence of Heterophil Antibodies in Infectious Mononucleosis. J. R. Paul and W. W. Bunnell, New Haven, Conn.—p. 90.
*Myeloid Cell Hyperplasia of Bone Marrow in Agranulocytic Angina. T. Fitz-Hugh, Jr., and E. B. Krumbhaar, Philadelphia.—p. 104.
Response of Reticulocytes to Iron. G. R. Minot and C. W. Heath, Boston.—p. 110.

Metabolic Studies in Addison's Disease.—Greene and his associates made a study of the chemical and metabolic changes observed in cases of Addison's disease, and the effect on these changes of treatment with the cortical hormone of the suprarenal. They emphasize that the clinical course of a case of Addison's disease may arbitrarily be divided into three stages: (1) the stage of initial destruction of the suprarenals; (2) the stage of the recognizable clinical syndrome, and (3) the terminal stage or crisis. Usually the disease is not recognized until the second stage is reached. At this time there may be loss of weight, asthenia and definite undernutrition. The basal metabolic rate is reduced slightly and there is some reduction in the blood sugar. Such changes become less with treatment, and more marked in the periods of crisis. The quantities of the various constituents of the urine in Addison's disease corresponded to the lower levels of the usually accepted normal standards. Creatinuria was present in a considerable proportion of cases. Retention of practically all urinary constituents was noted in one case in the course of a period of diminished urinary output. The nitrogen balance of those patients who were losing weight was negative. The majority of patients gained weight as a result of treatment with the suprarenal cortical hormone. In such cases the nitrogen balance became markedly positive. The period of crisis was characterized by gastro-intestinal upsets, nausea and vomiting, pains, circulatory collapse, low blood pressure, dehydration and renal insufficiency. The effect of the last two dominated the chemical picture at this time. The authors consider the relation between the chemical and metabolic changes observed in cases of Addison's disease, and those reported in suprarenalectomized animals, and the use of these changes for the standardization of preparations of the suprarenal cortical hormone.

Enteral Administration of Insulin.—Bollman and Mann report that large amounts of insulin may be instilled directly into the duodenum, jejunum or ileum without any appreciable effect on the sugar of the blood of normal dogs, except for the slight effects when concentrated insulin was used. The addition of acid, blood or bile to insulin thus administered did not alter this. If insulin is injected into the lumen of an isolated portion of ileum the blood sugar of the animal is not affected, but small amounts of insulin given submucously produce typical hypoglycemia. Insulin gradually disappears from within the lumen of the ileum. With the doses used by the authors, sufficient insulin remains after one hour to produce definite hypoglycemia if the insulin is injected subcutaneously. Insulin incubated with ileac washings is not so rapidly destroyed. It would appear that the intestinal mucosa inactivates insulin so that it is not effectively absorbed. Small amounts of insulin may escape inactivation if sufficiently concentrated insulin is applied to the intestine.

Auricular Fibrillation.—McEachern and Baker made a study of 575 consecutive cases of auricular fibrillation confirmed by electrocardiographic records. The etiologic relationships to the various forms of cardiac disease are tabulated. The infrequent occurrence of the arrhythmia in the first decade of life is discussed and two additional instances are recorded. Emphasis is laid on the rarity of auricular fibrillation in syphilitic cardiovascular disease. In the authors' series, 35 per cent of the cases were associated with rheumatic heart disease and only 3 per cent with syphilitic cardiovascular disease. Note is made of the production of auricular fibrillation by the administration of digitalis.

Agranulocytic Angina.—Fitz-Hugh and Krumbhaar found myelocytes and myeloblasts in the bone marrow at necropsy in more than normal numbers in a case of typical "agranulocytic angina" in which the antemortem blood count was 200 white cells per cubic millimeter (all lymphocytes), i. e., a marked absolute reduction of lymphocytes and absence of all other white cells. Based on this and similar cases recorded in the literature, the authors raise objection to the current hypothesis of "granulocytic aplasia" as constituting the "primary" pathologic mechanism of the disease, and in its place they propose an hypothesis of "maturation arrest." As there is an absolute reduction of lymphocytes in the blood stream as well as of neutrophils and on account of certain analogies with pernicious anemia, designation such as pernicious leukopenia is suggested as preferable to the more widely used names for this disease.

Antisyphilitic Treatment in Tuberculosis Patients. L. Fisher, Waverley Hills, Ky.—p. 148.

Environments in Tuberculosis.—Sewall believes that nothing conduces more to clarity of perception or suggests new meanings in old phenomena than a formal reclassification of one's stock of knowledge. From this point of view he was led to consider various different factors which are confused together in the term "environment," and in the attempt to analyze the concept he was constrained to divide them into five different groups: the external environment, the internal environment, the voluntary neuromuscular environment, the vegetative environment (including the endocrine system) and the psychic environment. The author discusses these factors in their relationship to tuberculosis.

Basal Lesions.—Dufault presents a brief review of the literature on basal lesions. The prevailing opinion is that tuberculosis located exclusively at the base of the lungs is extremely rare. Five typical cases of basal lesions mistaken for tuberculosis are reported. The author believes that the bronchoscope is of considerable value and should have its place in all well equipped sanatoriums.

Diagnosis of Hip-Joint Disease.—Burlingame considers that in the differential diagnosis of tuberculosis of the hip, coxa plana, coxa vara, acute infectious arthritis and acute transient epiphysitis, the most difficult is in differentiating tuberculosis of the hip and infectious arthritis, especially in the subacute stage. The history of the acute onset in infectious arthritis, the absence of demonstrable tuberculosis elsewhere in the body, negative skin tests, all aid in the diagnosis. In hip-joint disease, beginning with pain, increased temperature and increased leukocyte count, the hip joint should be aspirated and cultures of the fluid taken in an attempt to demonstrate pyogenic infection. Coxa plana occurs during the middle years of childhood, between the ages of 5 and 10, while tuberculosis occurs usually between 3 and 5 years of age. In coxa plana the motion is limited chiefly in two directions, abduction and internal rotation, while in tuberculosis the motion is limited in all directions. Muscle spasm in coxa plana is mild and in tuberculosis severe. Roentgen examination demonstrates characteristic changes which are quite different from those of tuberculosis. In coxa vara symptoms are almost identical with those of coxa plana, except that the hip is frequently rotated outward. Coxa vara is nearly always observed in the neuter type of individual. Roentgen examination demonstrates typical epiphyseal separation, which confirms the diagnosis. Psoas abscess may frequently be confused with tuberculosis, but here the range of motion is limited chiefly in extension. There is often a mass palpable above Poupart's ligament and there is usually evidence of a lesion of the spinal column.

Tuberculosis and Toxic Goiter.—Frank presents a case in which toxic goiter and toxic tuberculosis occurred in the same patient. Some enlargement of the thyroid and mild manifestations of hyperthyroidism are common in tuberculosis, particularly in young female patients, but toxic forms, namely, toxic diffuse goiter and toxic nodular goiter, are rare.

Early Cellular Reactions in Lungs of Rabbits.—Vorwald describes experiments in which he noted that the cells that respond first to an intravenous injection of human-type tubercle bacilli in rabbits (0.1 mg. per kilogram of animal weight) are the polymorphonuclear leukocytes. This reaction, while transitory, is not one of negligible significance. It is through the agency of the polymorphonuclear leukocytes that the site of subsequent development of the tubercle is determined. These cells phagocytose the tubercle bacilli in the blood stream and stagnate in small accumulations in the capillaries where the current is slow. In this way injected bacilli are concentrated and localized. The focalized accumulations of polymorphonuclear leukocytes form the groundwork from which the epithelioid tubercles develop. Mononuclear exudate cells are preponderant in the cellular response after the first few hours (from fourteen to eighteen hours on). They mingle with the polymorphonuclear leukocytes, phagocytose and digest them and take up their content of tubercle bacilli. In this way, by replacement of the leukocytic mass, the mononuclear-cell tubercle, ultimately the epithelioid tubercle, develops. The increase in mononuclear exudate cells in the field of inflammation, in almost total absence of mitotic figures in such foci, indicates that the majority of reacting cells of this type are hematogenous in origin.

Paralysis of Hemidiaphragm.—Gale and Middleton report observations which led them to conclude that phrenic block, with resultant paralysis of the hemidiaphragm, relaxation and compression of the lung, produces a certain measure of physiologic rest. This rest is not complete when other mechanical factors are considered (namely, the action of the intercostal and scalene muscle groups). Following phrenic block there is overactivity of the intercostal muscles, as reflected in increased movement of the thoracic cage at the level of the third and eighth ribs on the homolateral side. This overactivity may well explain the unfavorable results obtained in a certain group of patients following this operation. Certain adjunct operations (scaleniotomy and upper intercostal neurectomy) have proved of definite therapeutic value when performed simultaneously with phrenic block or at a later date to supplement the latter. These procedures decrease or abolish the overactivity of these two muscle groups induced by phrenic block and at the same time conserve the desired results of the latter operation, thus promoting more complete physiologic rest.

Tuberculosis and Carcinoma.—Cooper reviews the literature relative to the association of carcinoma and tuberculosis. This includes several hundred reports of cases in which the two diseases were present in the same organ. In addition, twenty-four cases observed at the Mayo Clinic, and never reported before, in which malignant and tuberculous lesions were intimately associated are presented. The frequency of this association is fairly convincing evidence that the two diseases are not antagonistic. Tuberculosis may exist with all degrees of malignant tumor. The finding of tuberculosis in an organ or biopsy specimen does not exclude the possibility of malignant tumor.

Metabolism of Retina: Further Notes. F. H. Adler, Philadelphia.—p. 901.
*Subnormal Accommodation. A. de H. Prangen, Rochester, Minn.—p. 906.

Dystrophy of Corneal Endothelium.—From the study of twenty-two cases of dystrophy of the corneal epithelium, Peter concludes that the condition is progressive and reaches its maximum when the entire endothelium is destroyed. Vision is lowered to about 6/7.5 to 6/9 from this cause alone. It is a degenerative process which, probably, is caused by a lack of nutrition of the ocular tissues. Although it is found in association with senile and nuclear cataract, the two conditions are related only in being an expression of ocular complications in patients suffering from nutritional disturbance. The condition is of much more frequent occurrence than its general recognition would indicate. The cases reported were found in the author's practice during the last year or eighteen months. The dystrophy, when well advanced, can be recognized without the aid of the slit lamp, but with good technic the slit lamp verifies the diagnosis in a most satisfactory manner. Patients with endothelial dystrophy are poor risks for intra-ocular surgical procedures. The protracted recovery of the one patient on whom the author operated would lead him to operate reluctantly for lens extraction, unless the patient is informed as to the probable operative complications that are apt to be encountered. Although vision is considerably reduced in the final stage of the disease in the cases thus far examined, the condition did not progress beyond the stage of complete vacuolization. This stage seems to be a stationary one. There is no tendency to regeneration. Dystrophy, therefore, seems to be the logical term to apply to the process.

Tonoscopy.—According to Magitot, the term "tonoscopy" (Terson) designates the method by which one evaluates the blood pressure in the vessels of the retina. Tonoscopy has in a few years enabled one to acquire interesting information, concerning not only the ocular but also the intracranial circulation. For the therapeutist, it therefore completes in a useful manner the study of the retinal vessels. Its principal interest, outside of ophthalmology, is to supply the neurologist with information as to the state of the intracranial pressure. Although it is a young science and susceptible of being improved, the method is worthy of being examined by all ophthalmologists, and the author believes that in a few years it will become as current as the act of determining systemic pressure with the sphygmomanometer or ocular tension with the tonometer.

Subnormal Accommodation.—Prangen states that subnormal accommodation exists as a definite clinical entity afflicting persons who have not reached the presbyopic age. It might be recognized oftener if strict attention were paid to individual accommodative power and its interpretation. Focal infection, particularly dental infection, seems to be a major cause. Fixation of the near points, without range, is an interesting and significant feature in accommodative asthenia.

*Early Cellular Reaction to Tubercle Bacilli: Comparison of this Reaction in Normal and Tuberculous Guinea-Pigs and Guinea-Pigs Immunized with Dead Bacilli. E. R. Long, A. J. Vorwald and Lilian Donaldson, Chicago.—p. 956.

Asbestosis.—Stewart and his associates report two cases of pulmonary asbestosis. In the first case the symptoms were relatively unimportant. In the second case the disease was concomitant with tuberculosis and, with it, was the cause of death. The similarity between some of the features of tuberculosis in childhood and tuberculosis complicated by asbestosis is suggested. In asbestosis the lung is not the only organ invaded by asbestosis bodies. The authors show that the spleen and lymph nodes may harbor large asbestosis bodies. They believe that from the histories of the cases they report there appears to be a further need for study along the lines of prevention of this disease.

Experimental Arteriosclerosis. — Benson and his associates describe lesions in the aorta and other arteries in rabbits inoculated with streptococci from sclerotic coronary arteries, coronary thrombi and sinusitis. These lesions include acute arteritis with or without thrombosis and arteriosclerosis of the aorta and other arteries. The experimental changes are comparable with the corresponding arterial diseases found in man. Slight arterial changes were observed in monkeys following injections of streptococci, but the changes are regarded as inconclusive.

Hypervitaminosis D and Arteriosclerosis.—According to Vanderveer, the arteriosclerosis produced by him in rabbits by hypervitaminosis D is not specific. The earliest calcareous deposits in the blood vessels are in the form of an incrustation about the elastic fibers in the media, and are preceded by some change in the adjacent intercellular substance. Degeneration of the muscle cells of the media appears at a later period. In the author's experiments, the order of involvement of tissues showing calcareous deposits as a result of hypervitaminosis D, other than arteries, was: kidneys, stomach, heart, liver and lungs. Tissue degeneration due to a toxic process precedes calcification of these organs. The proliferative lesions occurring in the intima in arteries are not dependent on a primary degeneration of the media. No changes occurred in the bone marrow or in the parathyroids comparable to those found in hyperparathyroidism.

Cellular Reaction to Tubercle Bacilli.—Long and his associates describe experiments from which they conclude that prompt localization of tubercle bacilli is brought about by exudation of polymorphonuclear leukocytes and phagocytosis of the bacilli by these cells. Although the bacilli are at first widely spread and the initial polymorphonuclear reaction is correspondingly diffuse, aggregation of the leukocytes, containing all the bacilli injected, into distinct and separate foci soon occurs. The site of future true tubercle formation is thus determined, for the polymorphonuclears are soon replaced by large mononuclears, which, as shown by the experience of many other investigators, later develop into epithelioid cells with more abundant cytoplasm. The fact that replacement of the polymorphonuclear mass by large mononuclears did not occur appreciably earlier in the locally immunized testis, already full of mononuclear cells, than in the other testes of the series suggests that in these experiments, at least, the large mononuclear cells concerned in the reaction came directly from the blood stream and were not derived locally. An already present tuberculosis in the animal greatly accelerates the reacting capacity of the polymorphonuclear leukocytes. This may be looked on as simply one feature of a typical tuberculin reaction. Previous inoculation with dead bacilli brings about a similar allergic state, although the acceleration and increased intensity of inflammatory reaction over that seen in the normal animal are not nearly so great as in the truly tuberculous animal.

Immunity to Pneumococcus Types II and III.—When Ross fed the soluble specific substance of type II pneumococcus to rats, little or no increased resistance to the organism was obtained. When the specific substance of type III pneumococcus was fed, an increased resistance to the virulent organism resulted. The percentage of animals protected was smaller than when the whole or the dissolved cell is fed. When the specific polysaccharide of type I was fed, no immunity against type II or III was obtained, and the ingestion of the specific substances of types II and III did not protect rats against the type I organism.

Urea Tolerance After Unilateral Nephrectomy.—Karsner and his associates describe experiments which demonstrate that although for a month after unilateral nephrectomy in rabbits the remaining kidney shows diminished capacity to hold blood urea within the normal range, nevertheless after four months this function is maintained in essentially the same degree as if both kidneys were present. This does not imply that all activities of the kidney remaining after unilateral nephrectomy are potentially augmented, but the data offered justify the conclusion that as the remaining kidney undergoes enlargement its functional capacity increases and the process represents a genuine hypertrophy in the critical sense.

Suprarenal Cortex Extract.—The resistance of suprarenal-deficient rats to bacterial intoxication was significantly increased by Hartman and Scott by an extract of the suprarenal cortex. This was shown both for acute intoxication with killed Bacillus typhosus and for chronic intoxication with killed Staphylococcus aureus. During the height of the bacterial intoxication relatively large amounts of the cortical hormone were apparently required to maintain the animals. The authors consider it probable that a human pyogenic infection imposes a severe load on the suprarenal cortex.

Transformation of R Pneumococci into S Forms.—Alloway states that avirulent R pneumococci derived from S forms of a specific type may be changed by growth in broth containing anti-R serum and a heated, filtered extract of S pneumococci of a different type, into virulent S organisms identical in type with the bacteria extracted. This has been accomplished in the case of R strains derived from type II pneumococci, by the use of extracts prepared from type III and type I S forms. The constituents of the extract supply an activating stimulus of a specific nature in that the R pneumococci acquire the capacity of elaborating the capsular material peculiar to the organisms extracted.

Iron in Tuberculous Areas.—Menkin reports that repeated intravenous injections of ferric chloride are followed by an increase in the survival time of tuberculous rabbits. In the series of experiments reported by him this increase amounted to about 78 per cent over the average survival time of control rabbits. Tuberculous animals repeatedly injected with ferric chloride increase in weight during part of the period of these injections. The level reached in the series studied markedly exceeded that attained by control rabbits. Both control and experimental animals die of generalized tuberculosis. There is no indication at the time of death of any differences in the degree of pathologic involvement between the two groups of animals.

Bartonella Muris Anemia.—According to Marmorston-Gottesman and Perla, normal adult Wistar rats (noncarrier stock) are readily infected with Bartonella muris and develop a severe anemia if large amounts of infecting material are used. The normal adult rat of Wistar stock possesses a relatively high natural resistance to spontaneous infection with this organism. Bilateral suprarenalectomy in Wistar rats lowers the natural resistance to a subsequent infection with Bartonella muris. This procedure does not alter the type of tissue response to the virus but lowers the natural resistance of the rat to toxic effects of the infection. The acquired immunity to Bartonella muris conferred by a first infection is not broken down by subsequent suprarenalectomy. The authors believe that the mechanisms of acquired and natural resistance are dependent on different physiologic processes in the organism and are not merely quantitative variations of the same process as is generally assumed.

Disappearance of Bacteria from Blood Stream.—Cannon and his associates noted that the simultaneous intravenous injection into normal and actively immunized rabbits of equal quantities of living staphylococci or paratyphoid bacilli is followed by a distinctly accelerated rate of removal of the bacteria from the blood stream of the immune animals. This altered reactivity is due essentially to specific active immunization. The bacteria pass rapidly through the capillary bed of the lungs, extracellularly and dispersed for the most part, and become generalized through the blood stream. They are quickly removed from the circulating blood in the immune animals and less rapidly in the normal ones, by various organs, particularly the liver and spleen, where they accumulate in enormous numbers, become adherent to the lining membrane of the sinusoids of the liver and apparently to the macrophages of the spleen and are phagocytosed by the macrophages and leukocytes in these organs. Associated with this effect are morphologic changes in the bacteria as shown by swelling, loss of staining power and evidences of increased cohesiveness and decreased viscosity, these changes being apparent as early as two minutes after their intravenous injection. Since these changes are not seen to a marked degree within the lungs or other organs, they are probably the result of a local antigen-antibody reaction of a bacteriotropic type in the two organs generally considered to be most actively concerned with the production of immune bodies. By means of this accelerated bacteriotropic effect in the actively immunized animals, phagocytosis is facilitated and intracellular digestion of the bacteria is enhanced.

Arthus Phenomenon.—Sixteen out of seventeen rabbits actively sensitized by Davidoff and his associates to various antigens by repeated cerebral and intravenous injections showed on intracerebral reinjection of the same antigen local anaphylactic inflammation of the brain at the site of inoculation. Six out of twenty rabbits actively sensitized to either horse serum or egg albumin by extracerebral injection showed, on introduction of the homologous antigen into the cerebrum, local anaphylactic inflammation at the site of inoculation. The pathologic picture of the Arthus phenomenon in the brain of the rabbit resembled that seen in the skin, after allowing for differences in the fundamental structure of the tissues involved. None of the control animals exhibited lesions comparable to those found in the experimental animals. A few controls showed slight hemorrhages due to mechanical injury of blood vessels. Clinical symptoms of varying degrees of severity, often leading to the death of the rabbit, were observed in the sensitized animals. These symptoms were referable to the site of injection.

Ascending Infection to Kidney.—Carson states that since there is a free communication between the lymphatics of the muscular coat of the bladder and that of the ureter, the lymph current of both the bladder and the ureter is from the mucous coat toward the fibrous coat. The perivascular lymphatics communicate with one another in a transverse as well as a longitudinal direction by means of vertical and oblique branches. The lymphatics of the upper portion of the ureter communicate with the lymphatics of the kidney pelvis, and they in turn communicate with the lymphatics of the kidney which accompany the blood vessels forming a capillary network in the cortex, surrounding all tubules like the blood capillaries; the lymphatics of the cortex communicate with those of the capsule. Infections produced experimentally by the author by the injection of an eighteen-hour broth culture of (1) paratyphoid bacillus into the bladder, intramural portion of the ureter or into the wall of the ureter (1 or 2 cm. proximal to the bladder), (2) Staphylococcus aureus and (3) Bacillus coli into the muscular wall of the ureter (distal end) were seen to extend upward along the perivascular lymphatics into the kidney. The necropsies showed no evidence of infection elsewhere in the abdomen or thorax, with the culture from the heart's blood being negative in each experiment; when the organisms were injected into the lumen of the ureter no evidence of infection was produced, save in one rabbit in which a cystitis was produced by the bacteria injected.

Perinephric Abscess.—According to Fowler and Dorman, perinephric abscess is relatively uncommon, compared with surgical lesions within the kidney. The metastatic type is most important from the standpoint of etiology and diagnosis. Diagnosis in the early stages is most difficult. Routine urologic study is important in excluding primary renal disease but of no positive diagnostic value in the metastatic type. Chief diagnostic points are: (1) history of peripheral infections, particularly suppurative skin lesions such as furuncles, boils, carbuncles, paronychia, otitis media, coccus infection of upper urinary tract; (2) unexplained fever; (3) high leukocytosis; (4) roentgen examination, and (5) costovertebral pain and tenderness. As a treatment this is directed to the primary renal lesion in the secondary type. Nephrotomy or nephrectomy is usually required. In the metastatic cases simple drainage is usually followed by complete recovery. The authors emphasize the importance of thorough drainage.

Intradermal Immunization.—Corbus believes that the function of the skin is more than a simple sheath protector. Whatever irritates the skin, either mechanical or bacterial in nature, not only irritates the histocytic elements of the skin but also as a result of involuntary nervous stimuli promotes the production of polymorphonuclear leukocytes. The antigenic response from some toxins if given intradermally seems capable of producing general immunity for their respective bacteria. The author has obtained good results with intradermal immunization in infections of the genito-urinary tract caused by the gonococcus, staphylococcus, streptococcus, colon bacillus and tubercle bacillus.

Arrested Pulmonary Tuberculosis.—Fales believes that on account of the latency of pulmonary tuberculosis and the well being of patients following rest without corresponding changes in the anatomic condition of the lungs, lack of constitutional symptoms should receive but slight consideration in determining an arrest. On the other hand, constitutional symptoms, if found to be due to tuberculosis, may be considered an expression of activity. As it seems to have been conclusively demonstrated that physical signs, especially râles, are of no value in determining progression and retrogression of a tuberculous lesion, it follows that they have no place in a schema of classification. The roentgen ray must be considered the main reliance in determining an arrest or a healed lesion and should receive this place of prominence in a schema of classification. When, by the comparison of serial roentgenograms at quarterly intervals, a lesion is found which is hard and fibrosed and has remained stable for six months, one should consider that an arrest has been attained, provided an additional six months is passed with carefully graduated exercise and observation without reactivation of the disease.

Pneumolysis in Pneumothorax with Adhesions.—Taylor reports five instances of pneumolysis in pneumothorax with adhesions. All the patients had been receiving pneumothorax therapy for six months or more before the pneumolysis operation. The pleural pressure had been maintained as high as possible without causing objectionable symptoms. Adhesions were unyielding and were persistently obstructing suitable collapse. Cavities were unclosed, and diseased areas were not immobile. Clinical pictures indicated variable degrees of unfavorable progress. Then all were operated on by means of the thoracoscope and the electric cautery. Eight months or more since the adhesions were cut, all the patients have gained weight and have ceased coughing; they have decreased sputum, which is bacillus free; their body temperatures are normal and they are so generally improved that the outlook is more hopeful from every point of view. The results seem to illustrate the necessity for obtaining complete collapse of diseased areas at least in certain conditions occurring during pneumothorax therapy. They also appear to exemplify the use of the thoracoscope and the electric cautery as an efficient means for eliminating obstructing adhesions and thereby converting unsatisfactory cases showing rapid and sustained improvement.

Major Infections of Hand.—According to Koch, the major infections of the hand—acute lymphangitis, infections of the tendon sheaths and infections of the fascial spaces of the palm—present definite and unmistakable diagnostic criteria. Lymphatic infections should be treated conservatively and operated on only when there are unequivocal signs of pus formation. Infections of the tendon sheaths and fascial spaces of the palm should be drained carefully and adequately as soon as the diagnosis is made. In the postoperative care of hand infections the prevention of secondary infection, early mobilization and the maintenance of the hand in the position of function during the period of enforced immobilization are important details of treatment.

Intra-Abdominal Local Anesthesia.—Caron reviews some of the advantages, disadvantages and important technical points in the administration of intra-abdominal splanchnic anesthesia, together with the neuro-anatomy of the viscera. He states that local anesthesia for intra-abdominal operations is definitely applicable in cases in which general or spinal anesthesia is contraindicated, in cases of spinal anesthesia in which the anesthesia has waned, and is the method of choice in major abdominal procedures in all cases of prolonged debility from disease, and in the aged. Familiarity with the anatomy, and particularly the neuro-anatomy, of the field of operation is essential before one attempts to adopt this method. Sympathetic anesthesia can be established by injecting the solution into the mesenteries, adnexal supports, subperitoneally and perivascularly.

Primary Carcinoma of Bronchus.—Vinson believes that primary malignant disease of the bronchus is not rare. Any infiltration at the hilus or base of the lung may be the result of malignant disease. Pulmonary symptoms are usually present, but in some cases they may be mild or absent. Bronchostenosis is the most frequently observed physical sign of the disease. Patients suffering from malignant growths in the bronchus have had pulmonary symptoms for many years, and it is possible that prolonged pulmonary suppuration may predispose to the development of carcinoma. Bronchoscopy offers the only means of making a relatively early and accurate diagnosis of the presence of a malignant lesion of the bronchus and is usually indicated in chronic pulmonary disease if tuberculosis is an unlikely etiologic factor. Radium and roentgen treatment has been followed by beneficial results and should be employed unless contraindicated by extensive metastasis or extreme weakness.

Syphilis of Stomach.—McCann and Dumphy present a case of syphilis of the stomach in which the lesion involved the antrum, causing high-grade obstruction. This increased rapidly, despite vigorous antisyphilitic treatment, making surgical intervention urgent. The diseased antrum was resected and a posterior Polya-Balfour anastomosis made. The patient had a satisfactory convalescence. The specimen showed changes characteristic of syphilis, chiefly thickening of the submucosa and muscularis, lymphocytic infiltration, and obliterative endarteritis. Since operation, antisyphilitic treatment has been continued. At the present time, a year after operation, the patient is in excellent condition, has gained weight, has no indigestion and there is no anemia. The blood still shows a positive Wassermann reaction.

Takata-Ara Test.—Daffinee and Grzebieniowska believe that the Takata-Ara reaction cannot replace the spinal fluid Wassermann test in the diagnosis of neurosyphilis. The reaction is of more value as a corroborative test than as a diagnostic procedure. The Takata-Ara reaction provides an easy, rapid and reasonably accurate test for the detection of abnormal spinal fluids. The ease of performance and the simplicity of interpretation lend themselves to the use of the small laboratory or the practicing physician or neurologist.

Cellular Studies on Thyroid.—According to Zechel, two types of cells exist in the parenchyma of the thyroid: (1) the common thyroid cell, which is the far prevailing type, and (2) the less frequent large cells. This ignored type of cell is distinguished from the common cells of the thyroid in many respects; the cell bodies are larger and, in section, appear triangular, multangular or irregular, showing marked variations between these forms. When arranged in small groups they flatten one another on adjacent surfaces, hence giving rise to various shapes. The large cells are located more often in the interfollicular cell groups than in the follicular wall, and they occur in greater number in the regenerating than in the resting gland. They may be classified in two groups, those with nuclei possessing a distinct chromatin network, and those with nuclei staining densely and evenly. But the latter compose only a small group. In regard to the function it is believed that they are concerned (1) with the formation of new follicles, (2) with the production of colloid, and (3) possibly with the inception of follicular destruction.

Tumors of Bile Ducts.—Marshall presents evidence that benign tumors of the bile ducts are extremely rare, that carcinoma is by far the most common neoplasm of the ducts, and that carcinoma of the bile ducts is more common in males than in females. Gallstones were present in 43 per cent of the cases on which the author's study was primarily based. Obstructive jaundice was found in most cases and may be extreme, fluctuating in severity or intermittent. The presence or absence of pain seems to be of little, if any, diagnostic significance. Typical biliary colic is not uncommon with tumors of the bile ducts unassociated with cholecystitis or cholelithiasis. The specific cause of obstructive jaundice is not easily diagnosed before operation. Positive diagnosis is rarely possible. Obstructive jaundice is usually a surgical problem, regardless of the type of lesion that causes the obstruction. Surgical treatment should have a favorable effect because significant symptoms bring the patient to the physician early in the course of the disease, and the tumor is small, slow growing, and late to metastasize. Obstructive jaundice usually kills the patient before the tumor itself has passed the stage of operability. Operation on tumors of the bile ducts carries a high mortality because of the tendency to hemorrhage and the technical difficulties of operation on the biliary tract. Favorable results, however, are attainable.

Association of Liver in Disease of Biliary Tract.—Judd and his associates are certain that the condition of hepatitis or cholangeitis occurs regularly in the presence of cholecystitis. It is also true that this condition of the liver exists when recognizable change cannot be made out in the gallbladder or bile ducts. Probably, under these conditions, hepatitis is secondary to infection in some part of the portal system. It is well known that the liver has a marked detoxifying function and that these changes in the hepatic tissue at times may represent the reaction that has taken place as a result of neutralizing either bacterial or chemical toxins that have been brought to the liver by the portal circulation. The authors feel certain that hepatitis may occur as a primary condition and that symptoms which result from it are similar to those of cholecystitis. Furthermore, removal of the gallbladder in these cases of primary hepatitis will relieve the symptoms. In a group of cases studied, it was clearly shown that bacteria can be found in a certain proportion of these cases. It was difficult, however, to establish the importance of these bacteria from the standpoint of the hepatic change.

Primary Idiopathic Abscess of Liver.—Dixon and Murphy state that the occurrence of idiopathic primary hepatic abscess is relatively rare. The etiology usually is obscure. Diagnosis of primary hepatic abscess is seldom made. It should be based on a recent history of some intra-abdominal surgical procedure, remittent fever, the presence of an enlarged, tender liver, and positive fluoroscopic evidence. Treatment should aim at free drainage, the method instituted depending on the size and situation of the abscess cavity. The physical signs, symptoms and pathologic changes are briefly summarized by the authors. A report of one case is included.

Obstructions to Ureter Produced by Aberrant Blood Vessels.—Young calls attention to the fact that obstruction at or near the ureteropelvic juncture is not infrequently caused by vessels which run from the great vessels to the lower pole of the kidney. He reports two cases in which these vessels caused an acute flexure, kinking and obstruction of the ureter, in one case bilateral and in the other unilateral. In the bilateral case the aberrent vessels obstructing the ureter were clamped, divided and ligated. This was followed by a distinct postoperative reduction in the kidney function on this side. At the second operation he carried out a new procedure (a plastic operation) by means of which it was possible not only to resect the very redundant pelvic sac but also inclosing it to draw the ureter away from the veins so as to remove all possibility of obstruction. The result obtained in this case was completely satisfactory. The same procedure was carried out in the second case also with complete success. In the first case, drainage of a huge hydronephrotic sac was kept up for over a month by means of a retained ureteral catheter passing out through the penile meatus. This resulted in a restoration of this kidney, which was previously functionless, to practically normal function, so that it was possible to save this kidney and to carry out the conservative plastic operation on the pelvis with excellent results.

Adenocarcinoma in Meckel's Diverticulum.—Michael and Bell report a case of primary localized adenocarcinoma arising in Meckel's diverticulum, in a man, aged 67. The growth was removed and a lateral intestinal anastomosis was done. The patient is free from any symptoms of intestinal obstruction or extension of the tumor. Previously there have been described and reported only seven other neoplastic processes that were malignant; all were of the sarcomatous variety. A sedulous search of the literature reveals that this is the first case to be reported of a malignant adenocarcinoma of this type in a true Meckel's diverticulum.

Injection Treatment of Varicose Veins.—Weeks and Mueller believe that the injection treatment is the safest and surest method of ridding a patient of varicose veins. No mortality should occur if patients suffering from recent superficial phlebitis are excluded. This is an effective method of treating varicose ulcer and varicose eczema. In the authors' series, 88 per cent of such cases were healed, and remained so, according to the follow-up observations. The technic should be simple, and single injections at each treatment should be given. Quinine and ethyl carbamate is the solution of choice because of sureness of results and absence of cramp. Forty per cent salicylate solution is also an excellent sclerosing agent, but severe cramp accompanies its use. The authors have found 20 to 30 per cent sodium chloride and dextrose and sodium chloride mixtures unsatisfactory solutions for injections, as they are more apt to cause sloughs and, too, they account for the entire number of recurrences noted at follow up.

Abnormal Bleeding.—Wyllie and Ellis state that in arriving at a satisfactory conception of the causes of abnormal bleeding the three factors that may be involved must be considered; these are the platelets, the permeability of the capillary endothelium, and the blood plasma. Thus in the case of hemorrhagic purpura in which the process of bleeding involves a diapedesis of erythrocytes through unbroken capillary walls, the blood platelets, which in the majority of cases are much reduced, and the capillary endothelium have been variously held responsible. In typical hemophilia, on the other hand, in which bleeding does not occur with intact capillaries and in which the platelets are normal or slightly raised in number, the blood plasma is generally regarded as being the defective element. From the pathologic standpoint it would appear that in purpura there is a "platelet-capillary" complex responsible for hemorrhage, while in hemophilia the plasma is abnormal. Both these factors may be inherited or both may arise de novo. The mode of transmission differs in the two cases, however, since the hemophilic factor is sex-linked while the purpuric diathesis affects males and females equally. It is of interest to find, therefore, that purpura hemorrhagica occurs not infrequently in the females of hemophilic families. Although difficult to explain on a pathologic basis, a relationship between hemophilia and purpura exists. The evidence is as follows: 1. Abnormal bleeding of the purpuric type occurs in the females of some hemophilic families with, in certain cases, the full picture of thrombocytopenic purpura. 2. Isolated features characteristic of purpura occur in certain cases of hemophilia, and vice versa. 3. Occasionally alternation of the hemophilic and purpuric state may occur in the same individual. Similarly, the same clinical and pathologic picture may be present in primary purpura arising sporadically or familial in origin, and in purpura which is secondary to sepsis, toxins, or other pathologic conditions. In both primary and secondary types the platelet-capillary complex is affected. In considering cases of abnormal bleeding, therefore, it is well to remember that although the great majority can be conveniently classified, a number of atypical cases will remain to remind one that much of the classification is arbitrary and that no absolute division exists between certain disease entities.

Infantile Diabetes with Gangrene.—Lawrence and McCance report a case of gangrene associated with acute diabetes mellitus in an infant aged 18 days. Treatment with insulin resulted in a cure of the gangrene and complete recovery from the diabetes. The authors searched the medical literature from 1850 to the present day for cases of diabetes in infants under 1 year of age. Twenty-six true cases, including their own, are described and discussed. In two complete recovery was established

Tattoo Tuberculin Test.—According to Craig, the multiple puncture method compares favorably with the Mantoux and Pirquet tests in all forms of tuberculosis in the matter of reliability. It has distinct advantages over other methods in ease of procedure, speed of performance, absence of any but momentary slight discomfort, and absence of any tissue destruction even in the most violent reactions. It is of particular value when used in children, especially for a routine method applicable to large numbers. The fact that it requires no particular skill in its performance makes the method especially suitable for use by any one only occasionally carrying out a tuberculin test.

Juvenile Rheumatism.—McSweeney summarizes the results of four years' special study in juvenile rheumatism among

Cardiff school children. The survey showed that 16.9 per thousand of the school population were affected, of whom 5.82 were suffering from rheumatic heart disease. Further evidence of the relative decrease in the prevalence of rheumatic fever at the expense of the milder and more insidious forms of juvenile rheumatism was obtained. Among 550 case histories investigated, the onset of the disease occurred during the winter or spring months in 475 (66.3 per cent). Among 588 rheumatic children, 433 (73.7 per cent) developed the first rheumatic manifestation between the age of 5 and 10 years. Among 626 rheumatic children examined, 225 (35.9 per cent) were found to be suffering from permanent disease of the heart. An investigation of the social conditions under which 600 rheumatic children lived showed that almost 75 per cent of the children were not suffering from the effects of poverty or privation. Further support for the view that dampness of houses is a factor of no etiologic significance in juvenile rheumatism was obtained. The parents of rheumatic children were found to have themselves suffered from juvenile rheumatism in 44.7 per cent of 279 separate family histories investigated, and 385 rheumatic children were found to have 122 brothers or sisters affected with the disease. Although family relationships play some part in the causation of the disease, no conclusive evidence as to the infectivity of juvenile rheumatism came to light. In 6 per cent of 626 cases the onset of the disease was directly postscarlatinal, but the postscarlatinal cases were found to be less likely to present cardiac sequelae than those having the disease independent of scarlet fever. No distinctive type of rheumatic child was recognized, but a majority of the children were fair-haired and had either blue or gray eyes. The incidence of dental caries was found to be no higher in rheumatic than in nonrheumatic children. A clinical description of the earlier phases of rheumatic carditis is given, and the methods and results of hospital treatment in 222 cases are outlined. The significance of throat conditions in juvenile rheumatism is discussed. Figures are given to support the contention that the state of the tonsils is of little importance in the causation of this disease. Further evidence is adduced as to the limitations of tonsillectomy in the treatment of juvenile rheumatism.

Ocular Palsies.—Holmes states that in dealing with loss of the power of movement of any part of the body one usually distinguishes those varieties due to structural lesions of, or functional disturbances in, the upper motor neurons which carry impulses from higher centers to the motor nuclei and their nerves, and those the result of lesions of the nuclei and nerves which innervate the muscles directly. The latter are the lower motor neurons or the final common paths, for by them only can nervous impulses reach the muscles. This distinction of two types of paralysis can be profitably applied to the ocular movements, too, though here, owing to the inaccessibility of the muscles to direct examination, some of the characteristic features of each type of paralysis are not readily recognizable. One cannot, for instance, by the ordinary means of examination detect wasting of the ocular muscles or test easily their electrical excitability; but the essential differences are obvious, for in lesions of the upper motor neurons movements as such are lost and sometimes those that normally are excited by certain impulses *only*, while in disease of the lower motor neurons the muscles themselves are paralyzed and react to no nervous message. This can readily be seen by contrasting a left internal rectus paralysis with a palsy of conjugate movement of the eyes to the right, for in the former the left eye is not adducted whether the patient attempts to look to the right or to converge, while in the latter case the left eye comes into the inner canthus as readily and fully as the right when the patient tries to converge; the internal rectus muscle is therefore not paralyzed but fails to contract in a certain movement only; that is, looking to the right. This corresponds to the condition one so frequently meets in an upper neuron paralysis of the limbs, in which no movements may occur in response to voluntary effort but they can be excited reflexly or synkinetically. Owing partly to the necessity of an extremely accurate adjustment of the movements of the two eyes in response to numerous stimuli, and partly, perhaps, to the considerable distance apart of the nuclei from which the ocular nerves arise, the nervous mechanisms which control the ocular movements are more complicated, and according to the part of it which is involved two types of supranuclear palsy can be distinguished—so-called conjugate or associated paralysis in which no movement of the eyes in one or more directions can be obtained by any means, and the true supranuclear palsies in which movement of the eyes in certain directions is lost to certain stimuli only but can be affected by others.

Treatment of Glaucoma.—Elliot believes that the importance and value of ocular massage in glaucoma is not, even now, sufficiently appreciated. There are certainly quite a number of cases under treatment for raised tension of the eye in which massage is either not being used at all or else not to the fullest advantage. The technic is simple, and any patient can be taught to use it for himself. Both hands should be used, and the index or middle fingers should be placed on the upper lid as far apart as possible and with the eyes looking downward. Alternate pressure with each finger in turn will rapidly lower the tension of most eyes, but the pressure must be made toward the center of the eye, whereas the great majority of patients employ a stroking movement which is of little value. Strong pressure should not be used; light, quick, almost butterfly movements will do more good and will not hurt the patient at all. In fact, he often offers the comment that he "hardly felt the massage and does it much stronger himself." It is, however, the light, quick pressure, with the fingers far apart and with every stroke toward the center of the eye that is by far the most effective.

Displacements of Uterus and Pelvic Floor.—According to Luker, one of the common causes of general ill health in women (headaches, fatigue, and aches and pains) is displacements of the uterus and pelvic floor. These are common in women who have borne children. As a result, there is a constant feeling of discomfort and pain. If there are, in addition, symptoms of menstrual dysfunction or disturbances of micturition, and these prey on the mind, carrying fear and apprehension of evils worse than those which really exist, then the joy of life is lost and chronic ill health results. Displacements of the uterus and pelvic floor therefore play an important part in the health of women and should always receive the most careful attention. Until thirty years ago, the majority of those suffering from these displacements were treated with rings and pessaries and were compelled to use a douche every day and receive medical attention every three months. Pessaries are not satisfactory, because they do not cure, require frequent attention, and, if neglected, set up discharge and sepsis. They may even be forgotten and give rise to a foul and blood-stained discharge suggesting carcinoma of the cervix. These instruments have now been superseded by carefully planned plastic operations, which give perfect results. Without doubt this is a great advance in gynecology, comparable with the treatment of hernia by operation instead of by truss. The author groups the displacements under three headings; (1) retroversion or backward displacements of the uterus, (2) weakness of the pelvic floor alone, and (3) descent of the uterus and pelvic floor. The two latter groups include all degrees of the condition generally called prolapse.

Chronic Meningococcic Septicemia with Bacterial Endocarditis.—Stevenson reports a case of chronic meningococcic septicemia with bacterial endocarditis which was characterized by prolonged fever, mainly of a daily intermittent type with occasional rigors, with pronounced weakness and loss of energy, and with symptoms that may be grouped as a meningismus. No benefit accrued from specific serum treatment: in fact, the impression of the clinician was that it exacerbated the symptoms, perhaps by liberation of endotoxins. The infection was due to the meningococcus, as shown by the cultural and serologic tests. It was isolated by blood cultur and the organisms were found as a rule in smears or sections of minute abscesses in various organs. The septicemia was associated with a recent endocarditis, producing toxic changes in the liver and kidney (in the latter probably of some standing), petechiae in the skin, buccal mucosa, pericardium, endocardium and leptomeninges, with minute abscesses in the kidneys, right suprarenal, lung, heart muscle, and in the thickened pia-arachnoid at the base of the brain. The pyemic condition must have developed shortly before death, as evidenced by the size of the abscesses. An acute leptomeningitis was not present, but some of the veins in the pia-arachnoid and of some of the penetrating vessels in the surface of the cortex were packed with polymorphonuclear leukocytes. It is believed that the positive culture from the pia-arachnoid over the vertex and the positive smear from the subdural exudate were due to infected cells escaped from ruptured vessels. A patchy chronic meningitis was present which may have been the residue of an early attack of acute meningitis occurring at the commencement of the illness but recovered from, and the same may be surmised of the subdural exudate.

Psychologic Aspects of Opium Addiction.—The experience of Chopra and Bose so far as the opium habit in India is concerned is that in the withdrawal or abstinence symptoms there is a predominant psychic element which can be overcome if the circumstances demand it. This is amply shown by experience of convicts in jail, and men under war conditions habituated to large doses of the drug for years who have to give it up suddenly and yet suffer no marked discomfort or withdrawal symptoms. During the treatment of addicts to rid them of the opium habit, opium can be largely or totally replaced by substances such as gentian or nux vomica preparations in pill form. A series of cases reported by the authors show that if the patient is not aware that he is taking opium, the drug can be effectively given for weeks or months for its therapeutic effect and can be stopped at any moment without producing abstinence symptoms. Physicians, therefore, need not hesitate to use opiates in special cases when these are indicated, provided they conceal the identity of the drug from the patient. The authors now regularly use opiates in this manner in the treatment of asthma, amebiasis or any other condition in which they are likely to benefit the patient. Opiates given in this manner can also be effectively used to detect malingering.

Undulant Fever and Brucella Abortus.—According to Thompson, some attempt must be made to explain the absence of undulant fever in Ireland, where bovine contagious abortion is second in importance only to bovine tuberculosis. Presumably it is due to the low virulence of the Irish strains of Brucella. At least two varieties of Brucella abortus are described, the bovine and the porcine. The former variety is commonly isolated from milk and infected cattle and is of low virulence for guinea-pigs and apparently also for man. The porcine type, as isolated from cases of hog abortion and occasionally also from cattle, shows slight cultural and metabolic differences from the bovine variety, and produces more severe lesions in guinea-pigs, often with multiple abscess formation. The more serious cases of human infection appear to be due to the porcine strain. It is questionable whether there are justifiable grounds for describing two varieties of Brucella abortus, and it would appear more logical to assume different degrees of virulence in one variety, only the more virulent strains being capable of infecting hogs and man.

Urethritis Caused by Crystals in Urine. J. E. Marcel.—p. 825.

Therapeutic Influence of Exfoliative Erythrodermia on Evolution of Syphilis.—Bernard believes that a review of the literature and his own personal observations do not warrant the belief that cure can follow exfoliative dermatitis during the course of syphilis. There are some instances of visceral, cutaneous, mucous or serologic syphilis which may give the appearance of recovery in the sense in which one can scientifically speak of recovery in syphilis. One should not be too confident in so-called posterythrodermic recovery but should continue treatment, not forgetting that an intolerance to one therapeutic agent may cause an intolerance to other antisyphilitic remedies.

Splenomegaly Before and During Chancre.—Dreyfuss reviews thirty-seven cases of syphilis in various stages in which he examined the spleen. On the basis of his observations he draws the following conclusions: From a diagnostic point of view moderate splenomegaly is an almost constant sign and appears usually early in the course of primary syphilis. It is a reliable sign in the differential diagnosis of doubtful cases. With regard to therapy, the author's observations show that the date of generalization given in textbooks as the fifteenth day of the chancre is too late since a sign of visceral generalization as absolute as splenomegaly was observed, in a favorable case, three weeks before the Wassermann reaction became positive.

Action of Lumbar Puncture on Cardiac Rhythm, Especially in Patient with Lesions of Central Nervous System. P. Veil.—p. 680.

Researches on Mechanism of Sedimentation Test.—Taking for granted that the rate of sedimentation is a plasma reaction, Achard and his co-workers undertook the study of sedimentation in relation to the number of red blood cells, their hemoglobin content, the number of white blood cells, the relative proportion of serum proteins (albumin and globulin), and fibrinogen. They also studied the lipoid equilibrium, certain crystalloids, the plasma chlorides, total nonprotein nitrogen, and the changes in alkali reserve. Among the pathologic states they compared obesity, gastric ulcer, neoplastic disturbances, pernicious anemia, catarrhal jaundice, cirrhosis with ascites, lipoid nephrosis, cardiac insufficiency, diabetes insipidus and Addison's disease. They concluded that the factors that can be accorded importance in the sedimentation of red blood cells are, first, the different protein fractions of the plasma, second, the number of red blood cells and their hemoglobin content, and finally the decrease in nitrogenous substances and changes in the acid-base equilibrium. The influence of the lipoid equilibrium seems negative and the influence of plasma proteins is uncertain. The mechanism of sedimentation seems very complex and subject to various influences such as surface tension, and electric charge. But in spite of the complexity in the phenomenon taking place during the changes in sedimentation, there is a certain relationship to the development of the morbid phenomena and the general status of health. The study of sedimentation can consequently furnish some indications as to the development, prognosis and treatment of certain diseases.

Multivitamin Diets in Digestive and Nutritional Disturbances Following Infection. R. Dubois.—p. 337.
*Efficacy and Dosage of Antidiphtheritic Serum. A. B. Marfan.—p. 351.
Blood and Urine in Physiologic Jaundice of the New-Born. Lereboullet, J. J. Gournay and Detrois.—p. 356.

Efficacy and Dosage of Antidiphtheritic Serum.—Marfan discusses the serum treatment adapted to a child aged 4 years with malignant diphtheritic angina, ordinary diphtheritic angina and laryngeal diphtheria with or without angina and considers the treatment of diphtheria in the new-born. He believes the important factors in treatment are the time and the dose of the first injection—the time may be more important than the dosage. The association of antidiphtheritic with antistreptococcic or antipneumococcic serum is not necessary. He adds that it may be more satisfactory not to use serum and instead incorporate preventive vaccination by the use of toxoid.

*Tracheobronchial Adenopathy in Children: Clinical and Roentgenologic Aspects. A. le Marc'hadour, P. Dupire and R. Loé.—p. 441.
Inflammation of Liver and Cytolytic Power of Bile. J. Dumont.—p. 450.

Tracheobronchial Adenopathy in Children.—In four of eighty children examined by le Marc'hadour and his co-workers, fine submammary starchlike crepitations were noted. In each of these cases, the roentgenogram revealed the existence of pathologic hilus shadows in both the anteroposterior and profile films; in some instances the film also presented a fissural image. If these indications are not symptomatic of tracheobronchial adenopathy in the strict sense, the authors believe they may be valuable in tracing a tuberculous hilus that is masked under the form of interlobar pleuritis. The authors conclude that the clinical signs attributed to tracheobronchial adenopathy can be seen in the normal individual. The proportion of cases in which they coexist with hilus or lymph node lesions, revealed by roentgen examination, does not permit one to consider them as presumptive signs. Clinical examination alone does not enable one to make a diagnosis of tracheobronchial adenopathy. Anteroposterior and profile roentgen examination should accompany the other clinical maneuvers. The hilus or the pathologic mediastinal images are of two types: the one, heterogeneous and of irregular contour, is parenchymatous, the other, homogeneous and distinctly spherical, is probably lymph nodal. This disease is rare since, among the eighty children who had a number of clinical signs sufficient to make the diagnosis of tracheobronchial adenopathy, it was present only thirteen times.

*Changes in Serum Proteins in Diabetes Mellitus. M. Labbé and R. Boulin.—p. 1725.
Ventricular Rhythms and Arrhythmia. R. Lutembacher.—p. 1726.

Changes in Serum Proteins in Diabetes Mellitus.—Labbé and Boulin assert that the reports in regard to modification of the proteins of the blood in diabetes mellitus are on the whole contradictory. Their personal research over a period of two years includes 212 determinations on 100 patients. The authors used the following values for normal constituents in 1,000 cc. of plasma: total proteins, 70 to 84 Gm.; serum albumin, 42 to 56 Gm.; serum globulin, 23 to 33 Gm.; and the albumin:globulin ratio as 1.5 to 2. Their researches prove that in the absence of other complications that would modify the blood proteins, 68 per cent of the patients with diabetes mellitus have an increase in serum albumin, sometimes to enormous figures, but with an average at 61.85 Gm.; the serum globulin on the contrary is not modified in 56 per cent of the patients and the average figure is 29.01 Gm. In 61 per cent of the patients the total serum protein is increased to an average of 92.99 Gm. and the value of the albumin:globulin ratio in 58 per cent of the patients reaches the 4.36 figure, with an average of 2.32. Therefore, in more than half of the patients with diabetes mellitus, there is an increase in total serum proteins, principally an increase in serum albumin, and an elevation in the albumin:globulin ratio. Hyperalbuminemia is even more frequent (83.33 per cent) when there is a disturbance in nutrition. The duration of the disease and the age of the patient do not influence these figures. Several patients observed during coma, however, did not show any deviation from the normal (albumin:globulin ratio, 2.02). Diabetes complicated by pulmonary tuberculosis revealed hyperalbuminemia in only 50 per cent; complicated by cirrhosis it revealed hypo-albuminemia, hyperglobulinemia and an inversion in the albumin:globulin value to 0.88; one case, complicated by nephrosis, showed a normal globulin value, a fall in the albumin value and albumin:globulin value of 0.68; in three cases of bronze diabetes the average value for the albumin:globulin ratio was 2.64; while the serum proteins in two patients with diabetes complicated by exophthalmic goiter did not differ from those with uncomplicated diabetes. The usual therapy with or without the administration of insulin led to a decrease in total protein and albumin in 70 per cent and a return to normal in 50 per cent of the patients treated. But the improved conditions did not last and there were oscillations in results. The maximum values in total protein and particularly albumin are found in diabetes mellitus, not in conditions such as obesity and hypertension since these are hardly ever associated with diabetes with denutrition and in which the serum protein changes are the same as in diabetes without denutrition. The interdependence between glycosuria and the disequilibrium in blood proteins is proved when it is seen that in the majority of cases the blood proteins become more or less normal when the glycosuria disappears. Two other factors are to be considered; namely, the mechanism of the concentration of the blood and the disturbance in the elaboration of plasma proteins. Dehydration with increased concentration and thickening of the blood has been noted in diabetes and particularly during coma. At the same time there is an enormous increase in blood proteins, chlorides and urea, and an increase in erythrocytes. Concentration of the blood during coma does not explain the hyperalbuminosis; it also seems impossible to establish any law of causality between the volume of urine eliminated and variations in blood proteins; nor can one explain why the albumin varies more than the globulin. It is suggested that disturbance in formation of plasma proteins is really due to an overproduction of serum albumin and therefore due to a disturbance in hepatic function. Obesity with a similar disturbance may therefore be related to diabetes.

39: 1789-1804 (Dec. 5) 1931

*A New Hypertensive Syndrome. H. Vaquez and D.-M. Gomez.—p. 1789.
Antispasmodic Medication in Pathology of Intestine. P. Chêne.—p. 1793.

A New Hypertensive Syndrome.—Vaquez and Gomez assert that an isolated mean value for hypertension should be added to the syndromes of acute, paroxysmal or permanent hypertension. An increase in the mean pressure is its most important sign and can reveal unsuspected morbid conditions and explain their relationship and cause. This new value for hypertension is frequently found by chance in an apparently common disturbance, in the course of a syndrome with a suspected hypertension which is not confirmed by the usual sphygmomanometric procedures, or in the presence of cardiac dystrophies ranging from simple arrhythmia to angina pectoris with sudden and progressive failure of the heart. Elevation of the mean pressure is of great diagnostic value. It persists, in contradistinction to the extreme pressures which vary under various influences; the value is quite high, 4, 5 or 6 cm. of mercury above the normal value. The sphygmomanometric curves take the curious form of a "camel's hump." But this type of curve is not constant in the initial phase of the mean hypertension and, although diagnosis is positive when it is present, its absence does not authorize the rejection of such a diagnosis. The authors find that the elevation of the mean pressure in the course of pregnancy is a premonitory sign of eclampsia; that mean hypertension can run parallel to systolic hypertension or independent of it; that its persistence following eclamptic attacks ought to preclude a recurrence, and finally that its progressive diminution in the course of repeated crises means improvement and cure. Furthermore, the researches seem to concur with the conclusions of ophthalmologists that there is a relationship between glaucoma and dystrophies in the small or large vessels of the vascular system demonstrated as arterial hypertension with an increased mean pressure. It is further demonstrated that irregularities in cardiac rhythm are capable of causing hypertrophy of the heart and an elevated mean hypertension. This has as a necessary corollary a progressive increase in the size of the heart and in the diameter of the aorta. It is suggested that the study of mean hypertension may help to explain primary enlargement of the heart with unknown pathogenesis.

Aberrant Lateral Thyroids.—According to van den Wildenberg and Dupont, aberrant lateral thyroids are so seldom encountered that they have seen only two cases in 1,100 operations for goiter. The first occurrence was in a youth, aged 19, who had a voluminous bilateral goiter and five tumors the size of a hen's egg, three at the right and two at the left, strung along the lateral aspect of the neck, from the angle of the lower jaw to the supraclavicular fossa. No connection was found between these tumors at operation and they were all removed. Three months later the patient reappeared with another tumor of the same size but under the left angle of the jaw and corresponding to the extirpated one on the right. It also was removed. Microscopic examination of these tumors showed Hassall's concentric corpuscles within the thyroid tissue. The patient has remained in perfect health four years after the operation. The second occurrence was in a man, aged 63, who for several months had a painless tumor the size of a pigeon's egg in the right supraclavicular fossa. The tumor had enlarged during the previous five weeks. This patient showed a moderate benign hypertrophy of the thyroid slightly more developed to the left and in the right supraclavicular fossa a hard and immovable tumor of the size of a goose's egg. The patient did not have exophthalmos, tachycardia or tremors. At operation this tumor was found to be adherent to the surrounding tissues and to enclose completely the subclavian vein, which had to be ligated. Histologic examination proved that the tumor was malignant, and although the patient has had no local recurrence his general condition has steadily become worse. The localization of the tumors in the first patient and the existence of thymus tissue within the thyroid tissue of these tumors incline the authors to believe that they are an abnormal evolution of the lower branchial clefts. They recommend extirpation of all aberrant lateral thyroids on account of their tendency to become malignant.

Filhos's Caustic in Ambulatory Treatment of Chronic Cervical Metritis.—Chalier asserts that the best means of treatment for chronic cervical metritis is cauterization of the uterus using Filhos's caustic. Cauterization can be performed without hospitalization if certain precautions are taken. He mentions three conditions for successful and innocuous cauterization. The first condition is the necessity for a good instillation; the cauterization must be done carefully and under perfect asepsis. The second condition consists in the necessity for a good preliminary examination. This should include digital examination of the internal genitalia and also examination of the cervix uteri with a speculum. This examination should be repeated before each cauterization from the first to the last. Filhos's caustic is absolutely contraindicated in acute metritis and also chronic metritis with salpingitis. A residual adnexitis or a painful parametritis does not constitute a contraindication. The third condition consists in the avoidance of all intra-uterine maneuvers, particularly dilation, immediately preceding cauterization. In general, the author advises light and regular cauterizations; that is to say, they should be of an equal intensity at every point of the diseased cervical mucosa, but without too many repeated applications at any one place. In exceptional cases, thirteen or fourteen cauterizations may be necessary; but in the majority one, two or three treatments are sufficient. The treatments should be made at intervals of fifteen to twenty days. These precautions eliminated all accidents and most favorable results were obtained; in only one case of chronic metritis was it necessary for the author to amputate a cervix with a bistoury.

- Extent of Variations in Inorganic Composition of Living Tissues. F. Steffen.—p. 13.
- Parenteral Calcium Therapy in Influenza. C. Hablützel—p. 15.

Aspects of Schüller-Christian's Disease.—Gigon directs attention to a syndrome in which the hypophyseal symptoms predominate; namely, diabetes insipidus, or adiposogenital dystrophy, also acromegalic symptoms, exophthalmos and defects of the bones. After American authors, who have investigated this syndrome, it is designated as Schüller-Christian's disease. The author observed this syndrome in a woman, aged 48, and relates his observations. There was marked acromegaly, an enlarged sella turcica, also diabetes mellitus, polyuria, enormous lipoidemia, especially hypercholesterolemia and changes in the carbon, nitrogen and electrolyte contents of the blood. The bone defects consisted of osteosclerotic foci of lipoid granuloma in the diaphysis and metaphysis of the tubular bones, and other bones showed defects which were surrounded by osteoplastic formations. The author is convinced that these changes in the bones cannot be entirely explained as a result of acromegaly, but that they are in causal relation with the lipoidosis. Of the cardinal symptoms of the Schüller-Christian disease the following were present in this case: hypophyseal symptoms, especially acromegaly and hypercholesterolemia, also changes of the bones, exophthalmos and xanthomatosis. A symptom that is ordinarily not found in this syndrome but was present in this patient is diabetes mellitus. Another unusual factor was the age of the patient, for this form of lipoidosis occurs almost exclusively in young persons. Beyond the age of 40 the disease is rare.

Atypical Cases of Renal Tuberculosis.—Allemann reports several cases of renal tuberculosis with unusual clinical manifestations. The first group was characterized by colics, the second group by hematuria. In regard to hematuria, the author points out that it may also result from tuberculous ulcerations of the bladder. The third group of atypical cases of renal tuberculosis was conspicuous for its lack of symptoms. The renal tuberculosis was discovered in the course of a careful general examination. The author discusses the differential diagnostic difficulties on the basis of reports in the literature and of his own observations.

Malariotherapy by Means of Anopheles.—Pozzi employed malariotherapy in dementia paralytica by means of Anopheles;

but, instead of using insects captured in the adult stage and then infecting them, he preferred to employ mosquitoes raised in the laboratory. In the Clinica medica at Rome, he has established Anopheles breeding places, beginning with larvae in the second, third and fourth stage, and, by using a careful technic, has succeeded in keeping infected Anopheles alive up to six months. The author calls attention to the advantages of his method as compared with inoculation with malarial blood, and is convinced that it would be advisable to establish malarization centers, in order better to diffuse malariotherapy in dementia paralytica and in other types of morbidity.

Registering Visible Electrocardioscopic Heart Beats During Operations.—Egidi points out and explains the method of constructing and using, in ordinary operative rooms, an apparatus that converts electrocardioscopic records of the currents emanating from heart muscle into readily visible forms.

Relations Between Uricemia and Oxalemia. G. Corradini and C. Pegoraro.—p. 665.

Roentgen Diagnosis of Chronic Appendicitis.—Becchini concludes from his researches that the morphologic details derivable from a roentgenologic examination of an injected appendix have only a coadjuvant value for the diagnosis of appendicitis. They do not constitute specific pathognomonic signs, owing to the fact that most of such details may be simulated by the presence of endo-appendicular fecal deposits. Of the functional signs, one—namely, evacuation—has weight in completing the diagnosis, and, more particularly, the greater or less delay with which it is accomplished as compared with cecal evacuation. No value attaches to the mode of filling, as that is not an expression of appendicular functioning. The reduced or abolished appendicular motility is a sign of great value, as the pathogenesis in most cases is connected with adhesions and exudative formations. To the various reflex colic signs no diagnostic value can be attributed, owing to their lack of specificity for the disease in question. The epigastric pain that is elicited on pressing the appendix or its pain spots is of great diagnostic value. The diseased appendix fills more rapidly with the opaque medium than does the normal appendix.

Tubero-Infundibulohypophyseal Syndrome.—Macera and Fernandez discuss the abnormal observations in the case history of their female patient, aged 10 years, who for several months had suffered from recurrences of nocturnal fronto-occipital headaches, mental dulness, nycturia, polyuria, tumefaction of the abdomen, polyphagia, polydipsia, excitability, pains in the wrists, knees and ankles, and lately insomnia. Physical examination discloses appreciable roughness of the anterior tibial crests, hyperhidrosis of the head and hands, vasomotor disturbances of the face, ogival palate, short neck with thyroid enlargement, rapid pulse (90), abundance of painless adipose tissue over the abdomen, hips and thighs, increased micturition (3,500 Gm. in twenty-four hours) with excess of indican and traces of blood. Mentally the patient is generally apathetic but has unreasonable crises of excitability and is of slow understanding. Basal metabolism is increased 50 per cent and sugar metabolism is disturbed. The authors believe that the patient has an heredity tainted with syphilis, the more so as her mother has had four spontaneous abortions and her brother has polydactylism. From the clinical observations they are convinced that she is suffering from a tubero-infundibulohypophyseal syndrome because she presents the typical symptoms of anomalies in the metabolism of fats, water, salt and sugar, anomalies of sleep, hunger, thirst and perspiration, and disturbances of the vasomotor regulatory mechanism.

Arterial Pressure and Pulmonary Tuberculosis. A. Navarro Blasco.—p. 787.

Cholesterol in Pregnancy, Labor, Puerperium and the New-Born.—Pérez Velasco and Maurolagoitia y Unda, basing their conclusions on a study of ninety-five hospital cases, state that pregnancy produces a hypercholesteremia becoming manifest in the third month and ending with labor. Its origin is to be found in the corpus luteum, suprarenals, adipose tissue and retriculo-endothelial system. Cholesterol is in greater part synthetically produced by the maternal organism while a small percentage comes as such from the ingested foodstuffs. Hypercholesteremia in pregnancy is indispensable for the life and development of the fetus because from the beginning of embryonic life cholesterol is necessary for the building up of the fetal tissues and is later an integral material of the fetal endocrine glands. During labor, cholesteremia increases as the uterine contractions mobilize the cholesterol already in the walls of the uterus and prevent its passing into the placenta. During the puerperium the percentage of cholesterol in the maternal blood falls rapidly and comes to normal by the eighth or the tenth day, because large quantities are eliminated by the liver and these quantities are still larger in women who do not nurse. Nursing should be recommended to mothers: their milk being the great eliminator of cholesterol, nursing will prevent overloading of the liver and possible formation of biliary calculi. The amount of cholesterol in fetal blood, even when taken from the umbilical vessels, is variable and not in proportion to that found in maternal blood, and percentages in the fetus should be determined only from the blood of the umbilical vein. Cholesterol does not pass as such from maternal to fetal blood but is first reduced by placental lipases, which facilitate its passage through the placenta.

*Infantile Typhoid. J. L. Aldecoa y Juaristi.—p. 428.

Infantile Typhoid.—Aldecoa y Juaristi draws the following conclusions based on the study of the 1930 epidemic of Portugalete: Typhoid in infants instead of being exceptional is frequent. Flies are an important factor in its propagation. Infants with unaccountable fever of from four to six days' duration should be suspected of typhoid; the classic symptoms of the adult do not exist in infants, which nearly always develop bronchitis characterized by discordance between the intensity of the bronchopulmonary signs heard at auscultation and the unimportance of functional disturbances of the respiratory tract. Typhoid aspect of the tongue and sordes invariably follow the bronchitis. The temperature curve is shorter and less typical, although still approximating the typhoid curve. Roseola, splenomegaly and dissociation of pulse with temperature are infrequent. Diarrhea and constipation are not typical, although diarrhea with yellow feces predominates. Blood cultures in the first eight days are positive in 80 per cent of the patients; agglutination is early and constant; leukopenia is present with absence of eosinophils, lymphocytosis and diminution of neutrophils. Prognosis is good. All children 2 years of age should be inoculated against typhoid, and no child suffering from typhoid should be allowed to remain at home. Carriers should be followed up and sterilized. Well fed typhoid patients stand the disease better; there is no particular advantage in an exclusive milk diet. Hydrotherapy is the basis of treatment and calcium chloride is efficacious, while so-called intestinal antisepsis has no effect. Enemas are useless and often prejudicial. Typhoid vaccines should be used early in highly toxic patients. Relapses are infrequent and independent from alimentation.

Primary Inflammatory Tumors of Stomach.—Diez states that the title of primary inflammatory tumor of the stomach is justified because from the clinical point of view the disease is a nonspecific, infectious granuloma occurring in the walls of the stomach and is a protracted state of spontaneous healing of gastric phlegmon, from which it has to be differentiated. The disease is especially one of later life. Laparotomy discloses a tumor in the anterior wall of the stomach in the vicinity of the greater curvature with antral or fundal localization, at times involving a complete annular segment or the lesser curvature; ordinarily it is definitely cut off at the pylorus, the duodenum remaining intact, while toward the cardia the tumor vanishes gradually. Adhesions are frequent and predominate between the anterior aspect of the stomach, the inferior aspect of the liver, the anterior abdominal wall and the pancreas. The adhesions are soft, fibrinous, unorganized, easily detachable and destined to be absorbed. The gastric serosa is intensely red or pallid and edematous, smooth and shining. The tumorous part may present a thickening of more than 6 cm. and a consistency ranging between soft and leathery. The gastrohepatic omentum and gastrocolic ligament are swollen and often retracted. The lymph nodes present the characteristics of acute and subacute adenitis. The thickening of the gastric wall occurs especially at the expense of the submucosa, may be of edematous, myxomatous or lardaceous nature, and present multiple small abscesses which may fuse, producing the relatively frequent form called suppurative abscess-forming gastritis. Microscopically the mucosa is edematous with hyperplasia of the connective tissue, incipient atrophy of the glands and in the deeper layers leukocytic infiltration. The submucosa shows edema with fibrin formation and numerous hemorrhages of all sizes and in all phases of absorption. Between these are many lymphocyte nodules surrounded by a zone of neutrophil polymorphonuclears, which indicate the tendency to small abscess formation. The muscularis shows streaks of lymphocytes and bands of young connective tissue. The subserosa offers the same lesions as the submucosa with invasion of the fat-nodules by leukocytes. The serous surface is covered with a fibrinopurulent exudate. The symptoms correspond to three stages of the disease, invasion, activity and regression. In the first stage there is sudden epigastric pain, continuous, radiating toward the left shoulder or the spine; chill and general malaise mark the beginning of the rise in temperature, which rapidly reaches 40 C. (104 F.); nausea is followed by vomiting of alimentary, acid and bilious material successively; in a few hours the general condition of the patient looks serious with marked prostration, rapid pulse and low arterial pressure; slight meteorism of the abdomen with poor respiratory mobility and contraction of the rectus abdominis muscles; the epigastrium is painful on palpation and the lower segment of the abdomen is easily depressible although sensitive. This stage lasts from two to ten days with temperature around 39 C. (102.2 F.), incoercible vomiting, intense thirst, constipation and general poor condition, after which there is a rapid regression of the symptoms and establishment of the second stage. Here the predominant symptom is the epigastric tumor, of which the lower limit only is well defined. Its consistency is soft but always less than that of a carcinoma; it is dull on percussion and reduces the inner portion of Traube's semilunar space. During this stage, which lasts from six to ten days, there are exacerbations of the pain, fever, nausea and vomiting. In the intervals there are subfebrile temperature, persistent anemia and poor general condition. Involvement of the pylorus brings on an obstruction syndrome with rapid cachexia. Blood examination reveals a secondary type of anemia. Examination of vomitus of gastric juice shows the absence of free hydrochloric acid. Roentgenograms will complete the clinical picture with the finding of small, disseminated, diffuse spots representing traces of barium insinuated between the two gastric walls. The diagnostic point is that infiltration of barium delimits the greater curvature of the stomach, which continues with the adjacent parts without the slightest deformity or retraction. Primary inflammatory tumors of the stomach evolve naturally toward resolution with restitutio ad integrum of the gastric wall in from five months to one year's time, and with disappearance of adhesions. If the pylorus is involved, the patient dies from inanition and alkalosis. Resection of the affected part of the stomach has given excellent results. If the whole stomach is involved, it is better not to resect but to wait for spontaneous resolution.

Arteriosclerosis, Hypertension, Nephritis.—The theories on the correlation between arteriosclerosis, hypertension and nephritis, according to Salus, have undergone considerable changes in recent years. He discusses particularly the significance of the changes in the vessels of the fundus oculi. He shows that the so-called retinitis albuminurica is a gradually developing nutritional and metabolic disturbance which first affects the stratum pigmenti and the outer layers of the retina and which is recognized by its sequelae, mainly by the reparatory inflammation and by the fatty degeneration. The disease of the layers originates in their nutritional basis; namely, in the vessels of the choroid, or in the posterior ciliary vessels, respectively. The author further states that in all patients with retinitis albuminurica there exists or has existed hypertension. He also asserts that the so-called retinitis albuminurica has no relation to a renal disorder. A connection exists only so far as the two disturbances often concur. They are coordinated diseases of different vascular provinces. If in the course of an apparently benign hypertension there develops a retinitis the primary disorder can no more be considered as benign than as if severe renal or cerebral disorders existed. The now existing hypertension is the malignant form. Thus, retinitis has also a prognostic significance. However, in predicting life expectancy it has to be considered whether vital organs such as kidney or brain are involved. The usually quoted two year limit applies of course only to cases with simultaneously existing severe renal disease, and even for these not always. In toxic glomerular nephritis, pregnancy, scarlet fever and similar conditions the prognostic significance of retinitis is of course different. This form of retinitis is curable because the infection, which is the cause of the production of toxin, is curable, or the pregnancy terminates or can be interrupted. In regard to the terminology the author states that the usual designation of "retinitis albuminurica" or "nephritica" should be discontinued, but he admits that it is difficult to find a suitable term. He suggests the terms scarlet fever retinitis, pregnancy retinitis and retinitis in hypertension, the latter term indicating the presence of malignant hypertension, regardless of whether or not renal changes exist.

Modification of Anemic Funicular Myelitis by Liver Therapy. H. Nehls.—p. 2194.

Ray Therapy of Exophthalmic Goiter.—Prüfer gives the clinical histories of six patients who died in a coma following roentgen irradiation of an exophthalmic goiter. But although he assumes a relationship between the irradiation and the fatal comas, he also reports that in six other cases of exophthalmic goiter the results of roentgen therapy were favorable and that five other patients, who had not been subjected to irradiation, also died in a comatose condition. He does not wish to assert that in the six reported cases the irradiation was always the cause of the coma, but he thinks that it led to the manifestation or only exacerbated an already existing coma. From his observations the author concludes that greater discrimination is necessary in the selection of patients for roentgen therapy, and that patients with beginning coma should be excluded from irradiation. However, he does not wish to discredit roentgen treatment of exophthalmic goiter but only wishes to call attention to possible injurious effects.

Clinically Diagnosed Cases of Aneurysms of Cerebral Vessels.—Lemmel relates the clinical observations on three patients with ruptured aneurysm of an artery of the base of the brain. In all of them the condition was diagnosed before death and necropsy confirmed the diagnosis. The clinical manifestations were essentially the same in the three cases; namely, severe apoplectiform attacks with the signs of intrameningeal hemorrhage (meningitic syndrome and hemorrhagic cerebrospinal fluid), and with or without abolition of function. The attacks, which generally developed in healthy and comparatively young persons, often were successive. The author states that following the rupture the diagnosis is generally not difficult, provided the possibility of an aneurysm is thought of. By roentgenologic visualization of the calcified aneurysmal wall the diagnosis may even be possible before the rupture.

Pulmonary Edema Following Epinephrine Intoxication.—Wichels and Lauber report a case of late pulmonary edema after epinephrine intoxication, in a woman, aged 28. Experiments on animals revealed that the pathogenesis of pulmonary edema is extremely complicated and manifold, but they gave no pointers for a causal therapy of late pulmonary edema following administration of epinephrine.

Diabetes Mellitus as Secondary Disease.—In studies on 160 diabetic patients, Ferger found in 10 per cent of the cases a relation to a disorder of the gallbladder. In an additional 9.4 per cent of the cases the anamnesis revealed a previous disorder of the gallbladder or of the liver, but there was no absolute proof of a connection between this disease and the existing diabetes. The author considers as the cause of the relationship between these disorders the proximity of the organs and the plentiful supply of lymph vessels, for these factors make it possible that inflammatory processes spread from one organ to the other. For the same reason it is understandable that a diabetes may develop as secondary disease also in duodenal ulcer. In the last part of the article the clinical history of a patient with disease of the gallbladder is related. A dextrose tolerance test revealed a pathologic blood sugar curve, and the author considers this disturbance in the carbohydrate metabolism as the beginning of a secondary diabetes.

Diabetes Mellitus and Vascular System. — Leutenegger first reviews the literature on vascular changes during diabetes and shows that some authors maintain that there is a special form of arteritis, which is the direct result of diabetes. He then gives a summary report of 1,000 cases of diabetes which were studied for the presence of vascular changes. His clinical observations convinced him that there is no special form of arteritis that is a sequela of diabetes, for if diabetes did cause such a vascular complication, it should also be found in diabetic patients less than 40 years of age, which, however, is not the case. Likewise the statement of the investigators who maintained that vascular changes are present in 90 per cent of diabetic patients in whom the metabolic disorder has persisted for five years or more could not be corroborated by the observations in 1,000 cases, for in 65 of 133 patients in whom the diabetes had persisted for over five years vascular changes were entirely absent. The author found that arterial changes were present primarily in diabetic patients who were in the sixth or seventh decade of life, that is, at an age during which such vascular changes appear also in patients without metabolic disorders.

Diagnosis of Chronic Alcoholism. — In tests on thirty persons, Matossi demonstrates the different behavior of alcohol in the blood of persons who abstain from alcohol or who drink it rarely and in small quantities, to that in persons addicted to alcohol. In persons who are not habitual alcohol consumers, the increase as well as the decomposition of the alcohol in the blood is more rapid than in addicts. Whereas in those who are not habitual drinkers the alcohol has usually completely disappeared within five hours, in persons with chronic addiction to alcohol it is present for nine hours or more. This observation is valuable in the diagnosis of chronic alcoholism, and the author cites one case which clearly illustrates the reliability of this test. The alcohol content of the cerebrospinal fluid does not go parallel with that of the blood but persists much longer. This indicates that in the blood the alcohol is oxidized more rapidly than in the cerebrospinal fluid.

Importance of Argentaffine Cells.—Erös investigated the so-called yellow argentaffine cells of the gastro-intestinal tract and their relation to disturbance in the function of the glands of internal secretion. The experimental animals were dogs, cats and rabbits. In disturbances in which a removal of the thyroid or suprarenals or the administration of insulin had led to a decrease in the blood sugar, he noted that argentaffine cells at first (immediate action) decreased in number but later (delayed action) increased in number. When administration of epinephrine, the removal of the pancreas, chilling or hunger caused a rise in blood sugar, the argentaffine cells increased at first and later decreased in number. The author believes there is a close relationship between the number of argentaffine cells in the intestinal canal and the endocrine gland secretory function; the number of these cells can increase or decrease in accordance with the increase or decrease in the activity of the endocrine system; and these results can be reproduced experimentally. Whereas formerly no digestive or any other function was attributed to these cells, the author now finds that they are similar to the silver reducing cells in various glands of internal secretion, such as the suprarenals, hypophysis and pancreas. The silver-reducing cells present in the endocrine glands compare with those in the gastro-intestinal system, not only in the property of reducing silver but also in the property of containing chromaffin and lipoid.

Actinic Ray Therapy of Malignant Neoplasms of Tongue and Jaw.—Cieszyński and Meisels are of the opinion that roentgen treatment of tongue and jaw cancer is almost useless or, at best, its action results in amelioration of the subjective symptoms at the price of injury to surrounding structures. Moreover, direct irradiation by aid of localizers is uncomfortable to the patient, while it is doubtful whether it is of any more benefit than irradiation through the cheeks and neck. The failure of roentgen rays, they reason, is due to reduction in *radioconductivity of tumor tissue, and serious injury to surrounding* tissue will result before the neoplasm will suffer at all. Radium is their agent of choice, applied to the surface or by radiopuncture. In surface application the holders of Stents or the authors are suggested to hold a 0.5 mm. platinum tube containing radium salts in place. The doses are usually high. Radiopuncture is far superior. Platinum-iridium needles from 15 to 20 mm. long are introduced, under local anesthesia, into tumor tissue in the proportion of 1 mg. of radium to each cubic centimeter of tumor tissue. This treatment is most advisable in cancers of the frontal half of the tongue and mucous membrane of the cheeks; in the posterior part the combined treatment (surface and radiopuncture) gives better results. Surgical treatment should be resorted to in early cases that do not require extensive mutilation, also cases refractory to actinic therapy in which the necrotic tissue annihilates the radioconductivity. The primary lesions respond to this treatment if handled correctly. The metastases, however, usually early and abundant in cancer about the mouth, present a different problem; surgery is the only method of treatment.

*Late Symptoms After Gastro-Enterostomy and Resection of Stomach (Billroth II) for Gastric and Duodenal Ulcer. H. Lublin.—p. 1.

Late Symptoms After Operation for Gastric and Duodenal Ulcer.—Late symptoms arising after operation for gastric and duodenal ulcer are divided by Lublin into four groups: (1) postoperative ulcers; (2) hematemesis, melena and symptoms of gastric character without any definitely demonstrable ulcer; (3) symptoms of intestinal character, and (4) postoperative anemias not occasioned by bleeding. Males seem to be more predisposed to postoperative ulcers than females, whereas females seem more liable to get other postoperative complaints. The postoperative gastric complaints not occasioned by ulcer are due to different factors varying from case to case. Gastritis is of great importance. Adhesions and disturbances in the mobility play a less important part. There is no proportion between the subjective symptoms and their causes. This is due to a nervous condition occasioned by the digestive disturbances caused by the operation and by the operative intervention itself. In cases of definite ulcer and cases presenting a possible ulcer, symptoms arise a relatively long time after operation, whereas in cases without demonstrable ulcer they arise shortly after operation. More than half the patients on whom gastro-enterostomy is performed show stools looser than normal, with increase of mucus and diminished digestion of connective tissue after a Schmidt-Strasburger test meal. Increased fatty contents in the feces are found in 50 per cent of the cases. In only a few instances has increased iodophilia been found. Chemical examination of diarrheal feces shows marked digestive disturbances, while cases with a tendency to constipation show much milder disturbances or none at all. In the case of intestinal disturbances occurring prior to the operation, the chance of such disturbances occurring at a later date is augmented. The most important condition for digestion to take place to its normal extent is to maintain the physiologic way of emptying the stomach. The possibility of sufficient admixture of gastric chyme and duodenal juice is thereby assured and the reflexes occasioning the secretion maintained. A tendency to pronounced nonposthemorrhagic anemia is present in more than two thirds of the cases. Exclusion of the pylorus, whether done in connection with resection or not, appears particularly to predispose to anemia. The cause of nonposthemorrhagic anemia occurring after resection and gastro-enterostomy is unknown. It is probably to be found in functional disturbances of the digestive organs and associated factors brought about by the operation. After gastro-enterostomy the gastric acidity is often reduced; yet in some cases it is unaltered or even raised. Postoperative acidity varies not only from case to case but also within a comparatively short time in one and the same case.

**Examinations of Blood Sugar at Tuberculosis Sanatorium.* E. Svaar.—p. 1176.
*Typhoid Carriers in Western Norway: III. T. M. Vogelsang and M. Haaland.—p. 1183.
*Epidemic Croupous Pneumonia. A. Strøm.—p. 1208.
Two Cases of Erysipeloid. A. Lindaas.—p. 1217.

Gerson-Hermannsdorfer-Sauerbruch Diet in Tuberculosis of Skin: Results.—Bruusgaard and Hval used this diet, somewhat modified to suit Norwegian conditions, during the last two years in seventy-five cases of skin tuberculosis, of which sixty-two were lupus vulgaris, for an average time of seven or eight months. The immediate results have been good and highly encouraging. The diet, they say, has a generally stimulating effect on the natural defensive powers of the organism but does not act through formation of specific antituberculous substances in the skin. The tissue-absorbing action of the diet is notable. Fourteen cases are given in detail.

Examinations of Blood Sugar at Tuberculosis Sanatorium.—From his examinations of the fasting blood sugar in eighty-four patients with pulmonary tuberculosis, on admission for treatment and on discharge, Svaar concludes that determination of the blood sugar is of no value in prognosis.

Typhoid Carriers in Western Norway.—Vogelsang and Haaland report fifteen new typhoid carriers, together with recent cases of infection from previously known carriers. One typhoid carrier reported earlier has become abacillary without operation. In two cases in which cholecystectomy was contraindicated, cholecystotomy was done, with positive results in the one. Of the twenty-five patients with cholecystectomy nineteen, or 76 per cent, were cured of the infection, two died, and four gave negative results. In the cases showing persistent infection, the interval between infection and operative treatment was from seventeen to forty-five years.

Epidemic Croupous Pneumonia.—The epidemic described by Strøm occurred in an orphanage and was due to a type I pneumococcus. This pneumococcus was found not only in the sputum but in cultures from the nose and throat, during the disease and up to seventy-three days after the crisis. During the epidemic 33.3 per cent of the well contacts were carriers, and two and a half months later 16.9 per cent were. The strains from patients were more virulent to mice than were those from carriers.

STRICTURE OF THE UTERINE CERVIX *

ARTHUR H. CURTIS, M.D.
CHICAGO

In presenting a summarized sketch of my subject, the pathology and clinical features of obstructions and strictures of the uterine cervix, it is my hope that I may suggest some new points for consideration. One encounters cases of cervical stricture repeatedly every month, and I am increasingly impressed that these lesions are of outstanding importance—of such importance that they merit the attention not only of the gynecologist but of the internist and the general practitioner as well.

ETIOLOGY

Cervical strictures in younger women occur most frequently in those who give a history of genital infection or instrumentation. Gonorrheal infection, particularly in those cases in which there has been considerable treatment of the cervix, is perhaps the most common of all causes of stricture. The use of radium within the uterus rivals gonorrheal infection. The cautery knife, so popular in modern times in the treatment of endocervicitis, may be useful in overcoming strictures, but it is also a potent factor in producing them. This is particularly true if repeated cauterizations are performed or if the cautery knife carries too much heat; also, if it has been necessary to cauterize high within the canal. Even the curet brings its toll of adhesions and cicatrices in the cervical canal; surely no one would curet the urethra without fear of a stricture, yet it is assumed that the cervix may be curetted with impunity although its apposed folds of mucosa are likewise subject to adhesion. A history of instrumental abortion is obtained from some patients presenting stricture who give no other history of injury or infection which might account for cervical obstruction. In cases of this nature there has usually been repeated instrumentation; i. e., an instrumental abortion with subsequent curettage, or instrumental abortion complicated by leukorrhea, with more or less treatment for relief of the latter.

Operations on the cervix contribute their share to the total number of cervical strictures. Pocketing of the canal above the obstruction is a rather common sequel. Even in cases in which the canal is left sufficiently roomy to permit unhampered passage of a dilator, there is a surprisingly high percentage of pockets immediately above the site of repair. As a rule, these are easily demonstrable by palpation with a dilator; sometimes they are evident only on bisection of the cervix.

"Senile vaginitis" is a well known condition. I wonder how many physicians are aware that this trouble is usually ascribable to senile stricture of the cervical canal. With cessation of the menstrual function there is atrophy, with more or less shrinkage of the lumen of the canal. Lesser lesions of varied etiology, which caused no annoyance in earlier years, may now suffice to make complete obstruction. There is first a retention of mucoid secretion, then contamination of the retained material, and, finally, a seeping through of the purulent accumulation when pressure sufficient to overcome the obstruction has developed within the uterine cavity. The incidence of pyometra in these cases will be noted later.

Mention of the etiology of cervical stricture would be incomplete without emphasis of the fact that many cases of stricture are encountered in women of childbearing age without history of infection or instrumentation. Among these, a considerable proportion are found in patients with fibroid tumors. On September 1, my first day of work this autumn, I curetted an unmarried virgin patient, aged 49, preliminary to radium treatment of small bleeding fibroids. After almost ten minutes expended in unsuccessful efforts to dilate, we resorted to anterior bisection of the cervix, in order to gain entrance into the uterus. An impenetrable, firm stricture, 1 cm. within the canal, a lake-like pocket above, and a second firm stricture at the internal os were all clearly exposed to view.

PATHOLOGY AND DIAGNOSIS

Perhaps cervical strictures have been overlooked all these years because the attention has been fixed on getting at the contents of the uterus. Impatience to discover what is beyond has caused neglect of obstructions in the canal. Even though a tight cervix has been encountered, the physician's thoughts have been concentrated on the pathologic changes above, blockage of the passage being passed by as insignificant. I can even now recall numerous occasions during bygone years when cervices were found which were passable only to a flexible probe or which required partial bisection anteriorly in order to permit entrance of the finest dilator.

Now that my associates and I have taught ourselves to look for obstructions, we explore the canal with extreme gentleness. Specially made small-caliber dilators are of great help. Recourse to anesthesia is sometimes advisable in the study of cervical obstruction in patients with an apparently impassable canal in whom there is intractable leukorrhea, suggestive of obstructed drainage. Also, in patients in whom hysterectomy is inevitable, an attempt is made to preserve the cervical canal uninvaded and intact, that it may be studied in unaltered condition following operative removal.

* Read before the Wisconsin State Medical Society, Sept. 10, 1931; the Michigan State Medical Society, Sept. 23, 1931, and the meeting of the Central Association of Obstetricians and Gynecologists with the Chicago Gynecological Society, Oct. 30, 1931.

It should be noted that obstruction is not always demonstrable with certainty on routine examination in the office; the sound may catch in the cervical folds or the canal may be impassable because of inaccessibility of the uterus or sensitiveness of the patient. In such cases the pathologic changes may be sufficient to warrant examination under anesthesia, and in a considerable number of instances it will be found that the obstruction was apparent rather than real.

On the other hand, true strictures are found sometimes when least expected. Routine study of the uterus after complete hysterectomy reveals more than an occasional incidence of clearly demonstrable cervical stricture. Among half a dozen uteri, saved for the artist during the three weeks of July devoted to the preparation of this paper, bisection in the frontal plane, preliminary to the making of sketches of the normal uterine canal, revealed one uterus with an incompletely occluding firm scar, above which was a valve-like corkscrew stricture; there was retained tarry fluid, but no ballooning, above the stricture. During the same three weeks, another patient presented a gristly, firm cervical occlusion slightly below the internal os; above this obstruction were seen an adenocarcinoma and much retained débris.

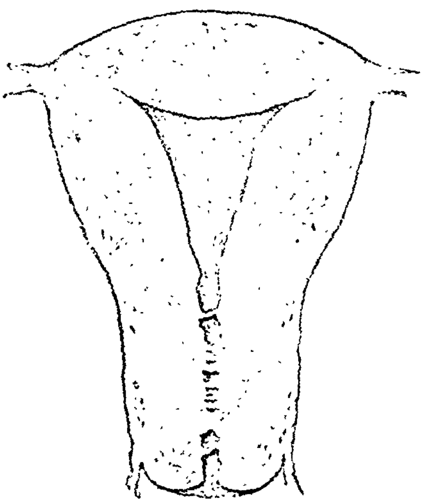

Fig. 1.—Schematic illustration, showing uterus bisected in the frontal plane, and cervical strictures incident to gonorrheal infection.

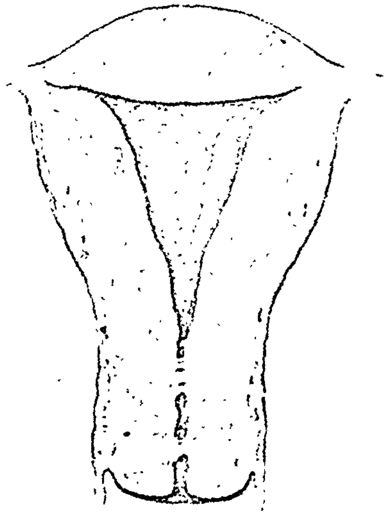

Fig. 2.—Schematic illustration, showing uterus bisected in the frontal plane, and strictures which developed subsequent to radium treatment.

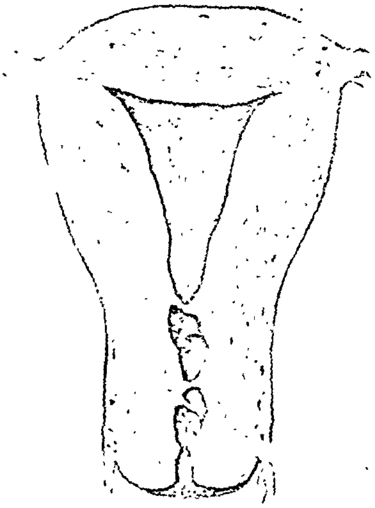

Fig. 3.—Semidiagrammatic sketch of posterior half of a uterus bisected in the frontal plane after hysterectomy for relief of profuse menstruation, persistent tarry discharge and dysmenorrhea. Multiple strictures are seen which are complicated by dilatation and pocketing of the cervical canal.

It was only recently that I came to a realization of the great number of interesting observations which may be made after bisection of the uterus in the frontal plane. An astounding amount of information is thus obtainable relative to the size and configuration of the canal of the cervix and the lower uterine segment—partial obstructions, strictures, dilatations, pockets, polyps, variations in size, in form and in content; all these are at once evident, provided only that the canal is left uninvaded and undisturbed before operation and that the removed uterus is studied after bisection in the frontal plane, care being taken to obtain two exactly symmetrical anterior and posterior halves.

The failure of pathologists to note a frequent incidence of cervical strictures is readily explicable. There is not only an ever present human tendency to overlook the new, as duodenal ulcer and endometriosis were overlooked until recent years, but there is also another important factor: the uterus is usually dilated and often curetted preliminary to hysterectomy, and thus all evidence of strictural lesions is destroyed, except perhaps pathologic dilatation of the canal, and the latter is readily overlooked. The amount of disturbance of the morbid anatomic structures which occurs incident to manipulations in the operating room is often considerable; James E. Davis of Detroit informs me that in a series of 1,200 uteri sent to his laboratory, 20 per cent were so mutilated by intrauterine instrumentation that they had to be discarded in making a statistical study of the details of uterine pathology. It is self evident that strictures will not be found in uteri removed after diagnostic dilation and curettage.

To digress for a moment: Study of the frontal plane of the multiparous uterus, after removal, reveals a frequent incidence of increased size of the cervical canal; funnel-shaped widening of the canal, with the base of the funnel at the external os, is apparently characteristic of a large percentage of these uteri. Just as a mother broadens out in the hips after bearing many children, her cervical canal also widens; this at least appears true in those patients who have more or less laceration of the cervix with extension into the base of the broad ligament. The funnel-shaped contour of the canal of the multiparous uterus may account for the considerable incidence of pocketings of the cervix which is encountered in patients after neatly done, but too low, cervical repair; an external os which is restored to normal size often passes upward into a balloon-shaped, permanently widened canal, unless excision of the diseased cervix has been carried to a relatively high point.

To return to a consideration of the details of cervical strictures: Ballooning of the cervical canal above the stricture may develop to a high degree provided there is obstruction sufficient to produce notable accumulation of mucus or retention of tarry menstrual blood. The pathologic changes produced by the retained material may be very extensive. In addition to a lake-like widening of the cervical canal, the capacity of the uterine cavity may be greatly increased; pyometra is commonly, and probably almost invariably, ascribable to cervical obstruction. Among other complications, we have encountered some cases of endometriosis in patients with anteriorly placed uteri, in whom the etiologic factor of this disease was evidently a menstrual backflow through the tubes, incident to cervical occlusion. (I have never seen pelvic endometriosis in a patient with a well placed uterus, except in these cases of marked cervical obstruction.)

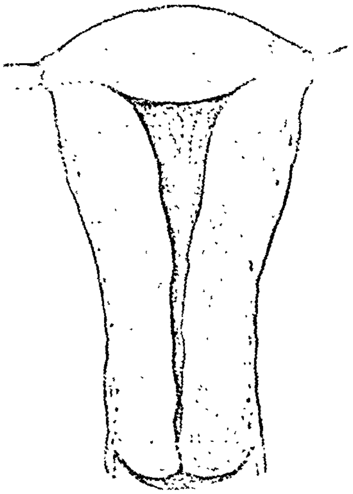

Fig. 4.—Schematic illustration, showing atrophic senile uterus, bisected in the frontal plane. Typical senile strictures of the lower cervical canal are present.

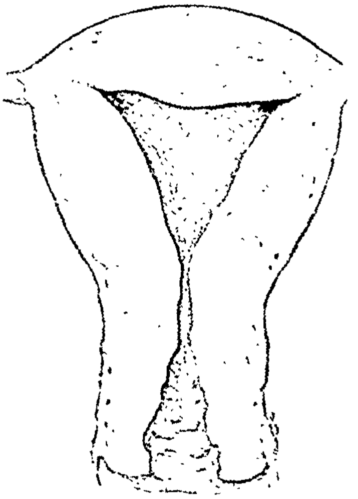

Fig. 5.—Multiparous uterus, bisected in the frontal plane after hysterectomy for persistent bleeding. Note the typical funnel-shaped widening of the cervical canal; this is notably frequent in association with deep lacerations of the cervix. Repair of the cervix should be sufficiently high to avoid postoperative pocketing of the canal.

To go a step further, I strongly suspect that nature's attempts to overcome strictural obstructions of the cervix may sometimes be a factor in the etiology of endocervical cancer; constant pressure and traumatism at the stricture site misplace cells into the deeper tissues, where they are free to grow uncontrolled. That cancer might thus develop is easily conceivable.

Inadequate drainage appears to be a chief reason for persistence of chronic leukorrhea of cervical origin. Recovery after treatment with the cautery knife is usually ascribable to the overcoming of gross obstruction in the cervical canal or to the establishment of drainage from microscopic foci of infection lodged in the deeper glands of the endocervix. With thorough drainage once established, nature does the rest. Looking backward, one must agree with the gynecologists of thirty years ago, who claimed that curetted patients were frequently cured of chronic leukorrhea; but it was the establishment of drainage incident to dilation of the obstructed cervical canal, not the scraping out of the uterus, which effected a cure.

It is a common experience in my practice to see patients well past the menopause who complain of the sudden appearance of profuse leukorrheal discharge. Obstruction of the cervix is commonly encountered in these patients. Just as it is now recognized that hemorrhage after the menopause is almost always diagnostic of uterine cancer, it may with equal assurance be stated that the otherwise inexplicable sudden appearance of profuse purulent vaginal discharge in a woman beyond the menopause is pathognomonic evidence of cervical stricture. Sometimes the obstruction has been largely overcome incident to accumulated pressure having broken through the barrier; even so, residual narrowing of the cervical canal with pocketing above is usually still evident. The relationship between "senile vaginitis" and cervical stricture has already been discussed.

It is also a common experience to have patients complain of persistent passage of tarry menstrual fluid. Although many such cases are attributable to disturbed menstrual function incident to disease of the ovaries, an occluded cervical canal is likewise a frequent cause of this disorder.

Symptoms referable to cervical obstruction are not limited to leukorrhea, the passage of tarry blood, dysmenorrhea, or occasional pyometra. Backpressure of retained secretions and menstrual blood is a hitherto unemphasized factor in the etiology of more widespread pathologic changes in the pelvis—a not rare cause of otherwise inexplicable low grade pelvic peritonitis, chronic tubal and ovarian disease, and endometriosis. Within the last several months, my associates and I have operated on two such patients, in whom the underlying cause of diffuse chronic pelvic peritonitis was apparently a backpressure into the upper pelvic zone incident to a badly diseased obstructed cervix.

TREATMENT

Every patient who has been treated with radium applied in chain tandem throughout the uterine canal should be kept under observation, for the purpose of preventing subsequent cervical stricture. There may be no symptoms despite the presence of a tightly constricted canal, but many patients return, a year or more after irradiation, annoyed by chronic leukorrhea or suffering from pelvic discomfort incident to retained secretion.

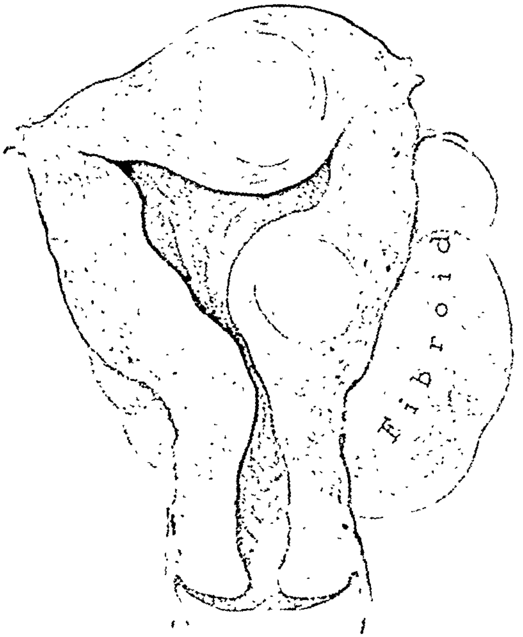

Fig. 6.—Multiparous uterus, bisected in the frontal plane after hysterectomy for bleeding fibroids. Distortion of the canal and "multiparous funnel-shaped widening" of the cervical canal are seen.

Dilation of the obstructed cervix, performed at the office, tends to be unsatisfactory except in cases in which there is simple occlusion at the external os, or a single thin valve-like barrier, or soft cobweb granulations in the higher canal. Even though dilation of a firm stricture is accomplished, recurrence of the obstruction is frequent. Not only is this true, but the traumatism inevitably associated with overcoming an extensive fibrous stricture may result in the eventual production of a still firmer fibrosis, which resists all attempts to dilate without anesthesia.

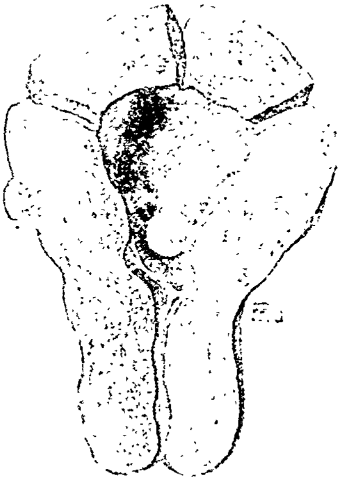

Fig. 7.—Hysterectomy for profuse leukorrhea and uterine bleeding. Longitudinal stricture and multiple "heart-valve" strictures of the cervix with dilatation above are seen. The uterus was opened by anterior incision.

Many older women, well past the menopause, have cervical canals which are impassable to dilators, but no notable discomfort is suffered. Such uteri need not be disturbed unless there is a suspicion of pyometra or malignancy. In the event that surgical intervention appears advisable, amputation of the cervix in women past the menopause does not yield ideal results; the cervix should often be bisected anteriorly and vaginal hysterectomy resorted to in cases in which this procedure reveals extensive pathologic changes.

In younger women, undilatable strictures and their associated pathologic changes are usually amenable to cure by a modified Schroeder operation or other procedure adapted to thorough removal of the diseased cervical tissues. Such operation is usually preferable to treatment with the cautery knife. It is essential that the canal be left widely patulous.

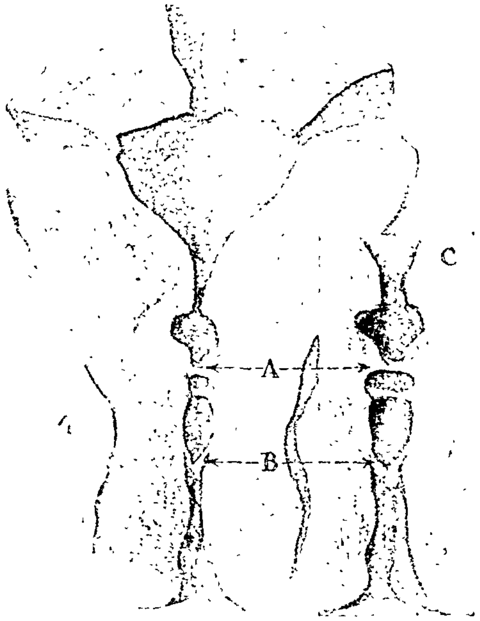

Fig. 8.—Multiple cervical strictures in a patient, aged 54, in whom the menopause occurred at 48. Purulent leukorrhea was noted for one month prior to operation; there was no history of previous infection or instrumentation. The uterus was opened after hysterectomy by anterior incision (not bisected in the frontal plane). *A*, cicatricial bands with retention of purulent material above; *B*, complete stricture impassable to dilator; *C*, cervix spread open.

CONCLUSIONS

1. Stricture of the uterine cervix is of sufficiently frequent occurrence to warrant the interest of every one concerned with pelvic diseases in women.

2. Important symptoms are persistent leukorrhea, dysmenorrhea, the passage of tarry menstrual blood, and pelvic discomfort of varied intensity. Any one or all of these symptoms may be wanting.

3. The pathologic changes include every conceivable variety of strictural obstruction. Dilatation and pocketing of the canal are frequent. Retention of mucoid secretion or tarry blood sometimes produces serious lesions of the upper genital tract and pelvic peritoneum.

4. Strictures may usually be diagnosed by intracervical palpation with Hegar dilators of small caliber. They are often easily demonstrable and readily overcome. At other times the diagnosis is difficult, anesthesia being required not only to reveal whether a stricture is apparent or real but also, when a stricture is present, to determine its nature and the extent of the complicating pathologic changes.

5. The treatment of stricture of the cervix follows well recognized surgical principles. Dilation may suffice; amputation of the cervix is often necessary, and vaginal hysterectomy is occasionally indicated in selected cases.

THE SYMPTOMATOLOGY OF FRONTAL AND TEMPOROSPHENOIDAL TUMORS *

FOSTER KENNEDY, M.D., F.R.S. (Edin.)
New York

Because of the paucity of definitely known physiologic centers in the frontal lobes, the diagnosis of tumor formation in these areas has long been difficult. Neurologists have been forced to look for main guidance to the results of pressure exerted backward on either the pyramidal tracts or their cortical origins, and to the presence of change in the mental state as a confirmatory factor. Alterations in mental and emotional condition appear more frequently here than from expanding lesions elsewhere. First is seen a lessening in power of attention; irrelevant replies are made. There develops a trivial and meaningless jocosity. Short periods of excitement occur, with foolish, inept and causeless laughter. There is a tendency to take offense easily, with, on the other hand, effusive apologies over trifles. Frontal epilepsy is frequent, characterized by petit mal and sudden attacks of mental confusion. With increase in pressure, hebetude replaces these earlier manifestations; the patient lapses at times into stupor and often can be roused only with difficulty. Frontal stupor is hebephrenic and less profound than is the morbid sleep induced by hypothalamic lesions; patients of the latter order can be roused to crystal-clear consciousness, whereas frontal stupors, by stimulation, are changed to a merely turbid or muddied awareness. There is frequent and characteristic yawning, and urinary incontinence appears earlier than would be warranted by the degree of drowsiness. In this connection, I observed a soldier who, from a through and through gunshot wound of the right frontal lobe, had persistent urinary incontinence as his sole neurologic symptom. Headache is less prominent than is usual; possibly the lowering of mental level makes complaint less articulate. There may come forced grasping or tonic perseveration of muscular action in the contralateral hand, from involvement of the anterior part of the corpus callosum and the frontopontocerebellar fibers. In my experience, the only station characteristic of disease in this area is titubation on the heels with a tendency to retropulsion. Compression backward often produces mild contralateral pyramidal tract signs, but one must remember that a meningioma placed anteriorly may press across the midline of the brain, giving rise to a similar motor reduction and to reflex changes on the same side as the main growth.

---

* Read before the International Neurological Congress, Bern, Switzerland, Aug. 31, 1931.

Individuals with appropriate cerebral dominance may suffer difficulty in speech emission with no loss of internal language; deterioration of function in the lowest part of the precentral gyrus may so impoverish the finest movements of the lips and tongue as to interfere greatly with speech. It is unwise, however, to assume that language representation must always be contralateral to the prevailing handedness. It has been shown that the apparent anomaly of the so-called crossed aphasias comes from such representation following right handed and left handed stocks independently of individual handedness; i. e., a right handed person in a stock dominantly left handed has the speech area more developed on the right than on the left side of the brain. It is therefore diagnostically inadequate to regard the handedness of the patient alone; an effort should be made to determine the prevailing handedness of his stock.[1] However, these criteria—personality change, stupid drowsiness, bladder and often rectal incontinence, pyramidal implication, and difficulty in the spoken word—may all be lacking or equivocal. One syndrome when present is diagnostically decisive: a speedy reduction in ipsolateral acuity of vision due to ipsolateral compression neuritis of the optic nerve lying below the frontal lobe, coincident with papilledema and normal vision in the opposite eye. From compression of the olfactory tract there is usually also under these circumstances anosmia on the same side. One may assert that if there is no doubt that a given patient has a brain tumor, if pansinusitis is excluded, and if in that patient a unilateral retrobulbar neuritis develops, with a central scotoma and reduced visual acuity, then it is certain that the brain tumor is situated in the lower part of the frontal lobe on the same side on which the retrobulbar neuritis and the primary optic atrophy have occurred.

This syndrome evolves when, from the inception of the disease, one or the other optic nerve has been directly subjected to pressure. If, however, the tumor is placed in the substance of the frontal lobe, not implicating at first the underlying optic nerve but producing a general rise of intracranial pressure, there will be brought about a bilateral papilledema, without central scotoma or loss of visual acuity.

The tumor or chronic abscess expands until at last it presses directly on the upper surface of the ipsolateral optic nerve. The following phenomena will then result: the papilla contralateral to the tumor will remain edematous, and visual acuity in that eye will remain good. In the ipsolateral eye, visual acuity will quickly fail, a central scotoma will develop, the edema will subside rapidly, and in a few days' time well marked temporal pallor will be seen ophthalmoscopically, an expression of atrophy which at a later period will be observed over the whole disk.

TEMPOROSPHENOIDAL TUMORS

Phenomena of lateralizing value in temporosphenoidal tumors consist of the perversions of contiguous functions. The motor tracts and their cortical origins may become so compressed as to give rise to a considerable degree of hemiplegia, which is always most severe in the face, less in the arm, and least of all in the leg. Deep pressure may introduce thalamic coloring: paresis of emotional expression in the opposite face, and occasionally increased sensitiveness in the opposite side of the body. Rarely, athetosis may appear. I have seen fluctuating pressure on the midbrain by a temporosphenoidal tumor produce fluctuating Argyll Robertson pupillary reactions.

However, the most accurate localizing sign has been described elaborately by Harvey Cushing: a quadrantic homonymous hemianopic defect in the contralateral visual field. This occurs from involvement of Meyer's loop of temporal optic fibers; should pressure continue, the pulvinar or the main optic tract may be damaged, giving rise to a complete homonymous hemianopia. When aphasia is present, it is constant in character: a poverty of recollection of names, resulting in circumlocution and descriptive speech. There is perseveration of verbal error, with no difficulty in emission; word blindness does not occur. Almost never is there any word deafness; spoken commands are accurately performed; verbal mistakes are immediately recognized and, if possible, corrected. The power of discrimination in the value of words is proved by the fact that inaccurate promptings are invariably rejected. There is no true loss of word memory, only a dimming of word recollection. The memories are for the most part intact, but their facilitation is difficult, and the patient is unable by force of will to bring them above the threshold of consciousness, below which they lie latent and beyond his conscious grasp.

The dramatic features of temporosphenoidal neoplastic disease consist of sudden dreamy mental states, their subjective projections, and the crude explosive sensations of taste and smell with characteristically related chewing reflexes and grimaces of disgust, repulsion and fear. These psychic fits often consist of the sensation of having lived through the exact scene then being enacted (le sentiment du déjà vu). So acute is the sense of familiarity that a feeling of prescience exists whereby the subject feels as though he can foretell the next action and the next word that will be spoken. To this voluminous mental state may be added a peculiar thought-feeling or a spectral word heard in a world of unreal consciousness. In such states, ghostly visitors may appear, phantoms appearing real but always known to be phantoms. One of my patients with a verified right temporosphenoidal tumor would often see men and women in eighteenth century court dress strolling across her New York apartment! A woman in Bellevue Hospital would be terrified by the repeated vision of a beckoning woman dressed in blue standing to her left side. A complex visitant of another of my patients was "a little old woman dressed in stinking rags who kept ringing a bell," a projected thought associated with a crude subjective sensation of smell due to uncinate irritation. It should be noticed here that the results of uncinate irritation are always disgustingly unpleasant, probably a tribute to the severity of the disturbance; the pleasantest odor enormously multiplied would be unendurable. It is an odd circumstance that such complicated hallucinations as these come always from disease affecting the temporosphenoidal lobes. One of my patients, the wife of a Sussex farmer, in her attacks always saw the room filled with Negroes; yet she told me that she had never seen a Negro in her life. However, she was the daughter of a sergeant stationed in Jamaica and was brought home to England at the age of 2.

[1] Kennedy, Foster: Stockbrainedness, Am. J. M. Sc. 152: 849 (Dec.) 1916.

Every individual, in his ascent from embryonic to adult life, passes through the stages through which the race has passed. The lower animals make their chief intellectual contact with their environment by means of the hippocampal lobes, which in man are relatively small and unimportant. It may well be that these areas subserve in man early intellectual functions which in later life are carried on by some higher mechanism. If this theory is true, then one may regard these apparitions as involuntary resuscitations of early, perhaps infantile, memory patterns. Almost every case of temporosphenoidal neoplasm presents, in my experience, some form of dreamy mental state, but similar events may occur within physiologic bounds. Not a few people have experienced panoramic and specific auditory projections when just on the threshold of sleep. Persons so affected have each their peculiar variety. My own species is a spectral phrase, always a cliché, such as "of course not" or "yes, surely," heard dimly like a stage prompt. Then comes a second or two of normality, long enough to recognize consciously the word as subconscious and to warn myself to be ready; then comes the silent spring-shutter change within the head, which breaks the thread of my previous thought so effectively that, should I not sleep immediately, I cannot recover the thread for several, perhaps ten, minutes. This period of inactivity following involuntary energy release is a characteristic feature of motor epilepsy and helps to classify properly these events of the predormitium as paroxysmal disorders, focalized, I believe, in the temporal lobe. Such considerations would indicate that thoughts and their wayward and fantastic sister, dreams, have dynamic neural patterns written by experience and released by altered physicochemical conditions.

410 East Fifty-Seventh Street.

Functions of the Skin.—The skin is one of the largest organs in the body, weighing, according to the data recorded by Vierordt, approximately three times as much as the liver. It is surprising, therefore, that aside from a partial understanding of its obvious protective, heat-regulating and sensory functions there is little knowledge of its physiologic activities or chemical composition and the factors that influence it. In the literature, moreover, there are many facts indicating the metabolic importance of the skin and suggesting that its functions may be as many and as varied as those of the liver. An inherent metabolism in the skin has been established by demonstrating the presence of enzymes affecting many of the complex constituents of the blood stream. Through the efforts of Wohlgemuth and his co-workers, and of Buschke and Klopstock and Melczer, the skin has been shown to contain an amylase, a diastase, glycolase, nuclease, tryptase, lipase, phenolase, catalase, phosphatase, sulphatase and carboxylase. Fahrig and Wohlgemuth and Ikebata found that skin, like other tissues, could produce lactic acid in vitro. . . . Urbach found that residual nonprotein nitrogen of the skin increased in cases of nitrogen retention. Ellinger showed that injected choline was stored in the skin. Milbradt considered the skin to be an important depot for cholesterol.—Kooyman, D. J.: Lipids of the Skin, *Arch. Dermat. & Syph.* **25**:245 (Feb.) 1932.

THE USE OF VEIN LIGATION IN THE TREATMENT OF ARTERIOSCLEROTIC AND DIABETIC GANGRENE *

HERMAN E. PEARSE, Jr., M.D.
ROCHESTER, N. Y.

Modern studies on the physiology of the circulation have resulted in a distinct advance in the treatment of the vascular diseases of the extremities, associated with sympathetic vasomotor spasm. But the management of those disorders due to organic arterial obliteration in which sympathetic overactivity does not occur has not shared to the same extent in this progress. This is no doubt due to the fact that, in the group of obliterative vascular diseases, the primary cause of the disorder is not known and cannot be materially influenced. The pathologic process is progressive, and as the disease advances there is a steady diminution in the size of the available arterial channels and even complete obstruction of some of them. Since the etiologic agent is not known and cannot be influenced, the functional restitution of the obliterated vessels is impossible, and until more knowledge of the causative agent is available, the only therapeutic hope is to preserve and stimulate the remaining vascular pathways to carry on a competent circulation. To this end, operations on the blood vessels are justifiable, but it must always be appreciated that such an attack is indirect and essentially palliative and in no way alters the cause of the disorder.

Since serious, obliterative peripheral vascular disease occurs most frequently in patients with diabetes, the advent of insulin has altered the treatment of these cases. Before this drug was available the appearance of diabetic gangrene often demanded amputation as a life saving measure, but now it is possible to control the diabetic state and to use conservative surgical measures in many instances without endangering the life of the patient.

There are two methods of conservative treatment of obliterative arterial diseases. The first may be termed the nonsurgical means of stimulating the peripheral circulation and includes the judicious use of heat or contrast baths, the use of rest in bed combined with appropriate exercise, such as walking or Buerger exercises or both, the use of massage or other physical therapeutic agents and finally the use of nonspecific protein therapy. The latter procedure is not without danger in cases of arteriosclerosis, for instances of thrombosis have resulted from its use. The second method is the utilization of conservative surgical procedures which have the stimulation of the circulation as their object. Included in the latter class are the operations of reversal of the circulation by arteriovenous anastomosis, periarterial sympthectomy, arterial excision and vein ligation.

The latter operation, obstruction of the vein, has been used in this clinic in the treatment of obliterative vascular disease of the lower extremity for the past four years. This procedure, originated by von Oppel in 1913, has never had a wide use and only thirty-one cases are reported in the literature. There is no report of a series of cases in which the results are known a year or more after operation. It seemed worth while to record our experience with vein ligation in occlusive arterial disease. A series of twenty cases was collected, in which the operation was done from one to four years ago and in which the late results were known. Cases without follow-up data and those in which the patient was living and under observation less than one year were excluded. This series is unselected. Although cases are included which undoubtedly would not be chosen at present, it is felt that their presentation in this way gives the clearest conception of the indications for and limitations of the procedure.

THE RATIONALE OF VEIN LIGATION IN OCCLUSIVE ARTERIAL DISEASE

The development of elective, therapeutic venous ligation is one of the most interesting subjects in modern surgery. The present conception is that ligation of a large artery should be accompanied by ligation of its companion vein. This point of view is directly opposite to the older teaching that the vein should be preserved at all costs. The original observation which brought about this change was made by von Oppel,[1] who had a clear conception of the part played by the vein in the mechanics of a reduced arterial circulation. He[2] says: "I speak sufficiently freely of the significance of the venous stasis, because in line with experimental investigations and clinical observations I showed that limiting the return flow of the ligated vein is accompanied by an increase in the arterial pressure." Again he speaks of "suction by the veins of the collateral arterial blood," and he says "If . . . the vein is ligated the arterial and venous pressure . . . are materially elevated." Von Oppel also first proposed vein ligation as a treatment of obliterative arterial disease. Four years later the principle of elective vein ligation became firmly established through the efforts of Sir George Makins[3] The observations of Sehrt,[4] Propping,[5] Tuffier[6] and van Kend[7] contributed at this time to clarify the indications for the procedure. Subsequently the investigations of Halsted,[8] Brooks,[9] Holman[10] and others[11] have added to the information about the subject. It has been established that if occlusion of a large artery is accompanied by ligation of its companion vein it results in (1) a lower incidence of gangrene, (2) an increase in functional capacity, (3) an increase in intravascular arterial and venous pressure, (4) an increase in the distal arterial circulatory bed, and (5) probably an increase in the functional efficiency of the capillaries, though direct evidence for this is lacking. From theoretical considerations it would appear that the volume flow should be diminished, and this has recently been demonstrated by direct readings.[12]

Because of its influence on the arterial circulation, therapeutic vein ligation has been suggested in (*a*) cases of sudden arterial obstruction, as by a ligature, (*b*) cases of arteriovenous aneurysm, and (*c*) cases of gradual arterial obliteration. It is obvious that the intravascular mechanics of these conditions differ but they have in common arterial ischemia and reduced arterial pressure. It probably is because of this that vein ligation has influence. Only cases of obliterative vascular disease will be considered here. In all, thirty-one cases are reported in the literature, in which this operation has been done, but the end-results of many are not given. In the absence of definite data, it is impossible to draw conclusions from these case reports, but the impression is gained that approximately 50 per cent of the cases were benefited, while the remainder were unimproved. There are an additional twenty cases recorded in which vein ligation was done in conjunction with periarterial sympathectomy or arterial excision.[13]

SELECTION OF SUITABLE CASES

A study of the twenty unselected cases here reported shows that eight had satisfactory results, eight were failures and four terminated fatally within one year of operation without amputation. This gives a successful result in half the living cases, which corresponds to the impression gained from the literature. It follows that, since vein ligation appears to have benefit in some instances, the patients designated for the procedure should be carefully selected in order to eliminate those who are unsuitable. From the experience which has been gained in the past, it has been found convenient to group the patients with obliterative arterial disease into three classes. This classification is based on the study of the history, physical examination, laboratory procedures and observations on the following points:

1. Location and extent of gangrene if it is present.
2. Color of tissues in the elevated, horizontal and dependent positions.
3. Presence or absence of edema or infection.
4. Character of the pulsation in the arteries of the limb.
5. Rate of return of circulation after blanching by pressure.
6. Apparent temperature of the extremities.
7. The amount and character of pain.
8. Appearance of the skin and nails.
9. Presence or absence of muscle atrophy.

The following supplementary procedures may be undertaken:

1. Intradermal saline test.
2. Pachon oscillometer or recording sphygmomanometer readings.[14]
3. Temperature readings with or without nerve block.

4. Roentgen treatment for calcification of vessels. (Recently arteriography with a new medium[15] has been used.)
5. Photograph or drawing to show exact extent of disease.
6. The Moschowitz test and the intradermal histamine test, which have occasionally been used.
7. Capillary microscopy (unsatisfactory because of the thickening of the epidermis in these cases).

In general, the five most useful observations are the amount of pain, the presence of gangrene, the pulsation in the peripheral vessels, the changes in appearance with shift in position and the rate of capillary return after blanching.

On the basis of the observations, cases are classified into three groups: (1) cases in which leg amputation should be done; (2) cases in which leg amputation should not be done, and (3) borderline cases.

Group 1 includes: 1. Cases presenting a poor circulation, which show either a spreading infection with lymphangiitis and perivenous inflammation or a gas bacillus infection. In the latter, leg amputation should be done immediately. Temporizing may lead to septicemia and death. 2. Cases presenting an incompetent arterial circulation. In this group are patients with a cold, pulseless, painful gangrenous extremity with atrophic muscles, hypertrophied nails and shiny skin which show ischemic pallor on elevation and cyanotic rubor on dependence. If the arterial circulation is hopelessly damaged, an amputation suitable to the patient's needs is the only beneficial procedure. Palliative measures are useless.

Group 2 includes cases in which there is infection, gangrene following infection, osteomyelitis of a phalanx, or ulcer formation, in the presence of a good circulation. The great majority of these cases will respond to proper conservative surgical measures, such as excision of the toes or drainage of infection. If the operation on the local lesion is not well executed, it may defeat the purpose of the therapy. Since the circulation is good, operations on the vessels are unwarranted.

Group 3 includes the borderline cases, in which leg amputation may or may not be needed. Some patients cannot be so neatly catalogued as those in the first two groups. They are in the borderline class, intermediate between those who should get well on conservative measures and those who are inevitably doomed to leg amputation. They show evidences of arterial obliteration by means of faint or absent dorsalis pedis and posterior tibial pulses, by slight delay in return of the circulation after blanching, by moderate coldness of the feet, by definite but not severe changes in color with shift of position, and perhaps by changes in the character of the nails and skin. Pain at rest, out of proportion to the local lesion, is absent. Gangrene or infection or both may be present. The pulse of the popliteal and femoral arteries is palpable. Since such changes indicate moderate but not hopeless arterial damage, it is highly desirable to stimulate the peripheral circulation. It is in these cases that operations on the vessels are justifiable and that vein ligation has been used as the method of choice.

Table 1.—*Published Cases of Vein Ligation*

Author	Year	Cases	Diagnosis	Vein Ligated	Result
Von Oppel[1]	1913	6	Arteriosclerosis	Popliteal	1 failure; 5 improved; "color and heat returns . . . with no edema"; relief of pain; period of improvement up to six months

VanGorder: Ann. Surg. **90**: 88, 1929	1929	7	Thrombo-angiitis	Femoral ext. iliac	For ulceration of amputation stumps in 2 cases (one bilateral), all improved; remaining 5 cases improved; no amputation in from 2 to 11 months follow-up
McWhorter, cited by Theis: Arch. Surg. **17**: 244, 1928	1928	3	Thrombo-angiitis	Femoral (?)	1 improved; 2 failures
McKittrick: Arch. Surg. **21**: 555, 1930	1930	1	Arteriosclerosis	Popliteal	Failure

There are some patients who are exceptions to the foregoing rules. They are the ones who already have one leg amputated and in whom symptoms of arterial insufficiency develop in the remaining limb. These unfortunate individuals deserve every consideration to prevent bilateral amputation. Since vein ligation is a simple procedure, done under local anesthesia, it is frequently tried even when there is little hope of improvement. The occasional saving of a limb encourages one to continue this procedure.

METHODS

In the management of cases of sclerotic arterial disease by conservative measures, patience and attention to detail are necessary. The vein ligation is but an incident in the treatment and must be associated with other measures to secure a good result. Among these are the careful preoperative preparation of the patient, the use of spinal or local anesthesia, the treatment of the local lesion and the postoperative care. The operative procedures used on the local lesion are adapted from those of McKittrick.[16] Gangrenous toes, osteomyelitis of a phalanx, ulcers and infections are treated surgically. Toes are amputated with a racquet incision, ending on the dorsum of the foot; the heads of the metatarsal are excised, and the wound is converted into a gutter, drawing onto the dorsum. In the amputation of toes or the drainage of infection, continuous incisions are used, dependent drainage is sought, and pockets are avoided. Wounds are irrigated with surgical solution of chlorinated soda during the postoperative period. For the venous obstruction, either the femoral or the popliteal vein may be used. The femoral vein is exposed in Scarpa's triangle, doubly ligated, and divided below the great saphenous vein. The popliteal vein is exposed in the lower part of the popliteal space and is occluded below its junction with the lesser saphenous vein. The femoral vein is easier to expose, and its ligation is probably preferable, especially if the pulse of the popliteal artery is weak. Ligation of the external iliac vein as advocated by van Gorder has not been used.

[16] McKittrick, L. S., and Pratt, T. C.: The Operative Treatment of Lesions of the Lower Extremities in Diabetes Mellitus, Arch. Surg. **21**: 555 (Oct.) 1930. McKittrick, L. S., and Root, H. F.: Diabetic Surgery, Philadelphia, Lea & Febiger, 1928.

During the postoperative period, general systemic treatment is given according to the conditions that prevail. The following accessory measures are often used: 1. The feet and legs are protected by a large cradle, which is kept warm by a light. 2. A Balkan frame with a hand trapeze is used to prevent pressure on the heels while the patient is moving about in bed. 3. Woolen socks are worn for warmth and to prevent skin excoriation. 4. The feet are bathed and anointed with hydrous wool fat daily. 5. Special care is given the back. 6. Supervised exercises, massage and gradual weight bearing are instituted.

RESULTS

The beneficial effects of vein ligation are the subjective sensation of warmth, the diminution in pain and the objective changes in the limb. These include accelerated healing of the local lesion, increase in the rate of return of the circulation after blanching, improvement in the color of the extremity, and increase in temperature of the part. It has previously been recorded[17] that a foot, formerly colder than the opposite side, is made persistently warmer by vein ligation.

The only possible detrimental effect of deep venous obstruction would be edema. Brooks[18] states that it is to be expected, but experience has shown that it rarely occurs. In approximately thirty operations of vein ligation, persistent edema occurred in only one patient. In this instance the placing of the ligature on the popliteal vein above the lesser saphenous branch obstructed the deep and a part of the superficial venous return. This result is ascribed to a technical error rather than to a fundamental fault in the method.

In table 1 is given the record of the case reports previously published. From this table it is seen that four-

Table 2.—*Case Reports*

Patient	Diagnosis	Duration	Local Lesion	Duration	Clinical Impression of Circulation	Dorsalis Pedis	Posterior Tibial	Popliteal	Femoral	Operation	Date	Result

[17] Morton, J. J., and Pearse, H. E., Jr.: Temperature Effect of Popliteal Vein Ligation in Thrombo-Angiitis Obliterans and Arteriosclerosis, Ann. Surg. **88**: 233 (Aug.) 1928.

[18] Brooks (footnote 9, third reference).

teen cases are diagnosed as thrombo-angiitis obliterans and seventeen as arteriosclerosis. A record of the cases reported from this clinic is given in table 2. Two are classed as thrombo-angiitis obliterans and the remaining eighteen as arteriosclerosis. This gives a total of sixteen cases of thrombo-angiitis, with ten cases showing improvement and six failure. Our own slight experience with vein ligation in thrombo-angiitis obliterans has been disappointing. In the group of peripheral vascular disease due to arteriosclerosis with or without diabetes, nine patients are reported as improved and nine as unimproved. In the series here reported, eight patients are improved after a year or more, eight have had leg amputation and four have died within a year of operation without amputation. Of the living patients, half have shown a successful outcome. This result is modified by critical analysis. For example, it will be seen in table 2 that case 3 is classed as showing a good circulation and that the pulse of the dorsalis pedis and posterior tibial arteries is perceptible. Such a patient has gangrene from infection and not from circulatory deficiency and would recover with proper treatment of the local lesion. This satisfactory result should not be credited to vein ligation.

If this patient, the patient presenting gangrene of an amputation stump (case 2), and those who died within a year (patients 1, 4, 8, 18) are excluded, there remain fourteen for analysis. Of the latter, four are classed as having a poor circulation without pulsation in either the popliteal or the femoral artery. All were failures. Such unsuitable cases should have primary leg amputation. Of the remaining ten patients, who are classed as having a fair circulation with a pulsating popliteal artery, nine had gangrene of the extremity. Of these ten patients, four (40 per cent) had leg amputation within a year and six (60 per cent) have had a satisfactory result with full return of function. This group represents properly selected cases according to the present conception.

It is felt that this series gives a fair idea of what may be expected from vein ligation in diabetic or arteriosclerotic gangrene, for the following reasons: The patients were treated by six different surgeons; the status of the peripheral circulation in the patients reported was good, bad and indifferent, and, though the conservative treatment of the lesion did not result in septicemia or death in any instance, the mortality rate from other causes was about average for such a series.

Too much should not be expected of any one procedure in these cases. Vein ligation should be only a part of the treatment of the patient and of the local lesion. Its use in appropriate cases is of value and often definitely improves the peripheral circulation so that a good functioning foot is preserved.

SUMMARY AND CONCLUSIONS

1. In obliterative vascular disease of the extremities, operations on the blood vessels are justifiable but are essentially palliative since they do not affect the cause of the original disorder.
2. The effect of venous obstruction in the presence of arterial insufficiency makes it a desirable procedure in appropriate cases.
3. Thirty-one cases in which this operation was performed are collected from the literature and twenty additional ones, followed for a year or more, are reported.
4. Analysis of these fifty-one unselected cases shows that approximately half were benefited, while leg amputation was done in the remainder after a variable period of improvement.
5. A basis for selection of cases is given which creates three groups: (1) those which show a hopelessly damaged circulation, requiring leg amputation; (2) those which result from infection and require only treatment of the local lesion, and (3) those in which there is a fair circulation, with a patent popliteal artery but absent peripheral pulses, and in which conservative treatment including vein ligation should be given.
6. Analysis of the suitable cases shows that in 40 per cent leg amputation was needed within a year, while 60 per cent had a satisfactory result with return of function.
7. Vein ligation should be considered as only a part of the care of these patients. Its use in appropriate cases definitely increases the efficiency of the circulation of the extremity and helps to avoid leg amputation.

PATHOGENESIS OF CHRONIC HEREDITARY EDEMA OF EXTREMITIES (MILROY'S DISEASE) *

JOHNSON McGUIRE, M.D.
AND
PEARL ZEEK, M.D.
CINCINNATI

The paucity of knowledge regarding the pathogenesis of hereditary edema of the extremities justifies the description of a characteristic case which we have had the opportunity to observe for several years and from which sections of skin have been examined on two occasions.

The earliest descriptions of this peculiar disease were published almost simultaneously by Nonne[1] and by Milroy.[2] Subsequently several additional cases have been described and various theories advanced concerning the etiology of the condition.

The characteristics of the disease may be summarized as follows:

1. The condition is always hereditary.
2. Only the lower extremities are affected.
3. There is no evidence of local obstruction or of the usual constitutional causes of edema.
4. The edema is persistent.
5. The state of general health is excellent and longevity is the rule.

As none of the recorded cases have come to autopsy and as there is no report regarding material obtained at biopsy, the pathogenesis of the condition remains obscure.

Among the hypotheses that have been advanced is the theory of Meige,[3] who believes that there is a congenital malformation of the trophic centers in the spinal cord, regulating the growth of cellular tissue. Rapin[4] postulates an embryonic dyscrasia of the mesoblast. Valobra[5] implicates the nervous centers controlling

lymph secretion. Spiller[6] suggests some endocrinopathy as the causative factor. Rietti[7] has demonstrated in one case the reversal of the albumin-globulin ratio. Milroy[8] in a recent article speculates on the rôle played by the vasomotor nerves in the causation of the edema.

Filarial invasion of the lymphatics and repeated attacks of streptococcal cellulitis have also been considered as possible etiologic agents. Hope and French,[9] in 1907, described curious acute attacks in cases of hereditary edema, with general redness and heat of the affected extremity, accompanied by chills, fever and general malaise.

REPORT OF CASE

Family History.—The grandfather of the patient had "swollen legs" and is the first member of the family in whom this condition has been noted. He was married twice and his first wife bore two daughters. One died in infancy of unknown cause; the second developed edema of the legs at puberty. Her children, two girls, were likewise affected with edema of the legs at puberty. By his second marriage several children were born, but information was obtained about only two of them. Both were males and had swelling of the legs, which began at about the fourteenth year. One, the father of the patient, has been married twice. By his first wife two children were born and have remained normal. One is 30 and the other 35 years of age. By the second wife two children were born, the patient and his brother. Both have edema of the legs.

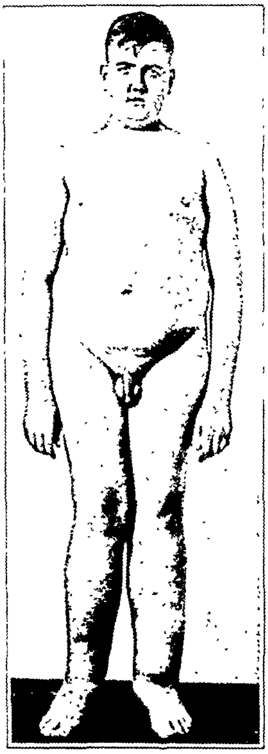

Fig. 1.—Appearance of patient in November, 1928.

Present Illness.—Two years ago, when 13, the patient noticed that his legs were beginning to swell. There was no pain, tenderness or constitutional disturbance. Since that time there has been progressive increase in the degree of edema, but until recently the only symptom noted was difficulty in walking, caused by the mechanical interference of the edema.

One month before admission to the hospital, the boy had a sudden acute febrile illness associated with a severe chill, headache, vomiting, tenderness and soreness in the right leg. The left leg was unchanged. He felt bad for four days thereafter, and then the symptoms disappeared. Two weeks later a similar attack occurred.

Physical Examination.—On admission, Nov. 24, 1928, the patient's temperature was 97 F., the pulse 90, and respirations 27. He weighed 205 pounds (93 Kg.). The patient was a fat boy, aged 15, with wide hips, unusually prominent breasts and scanty axillary and pubic hair (fig. 1). The external genitalia were underdeveloped. There was enormous edema of the ankles and of the legs between the knees and ankles. This edema was semisolid in character, pitting occurring only after prolonged pressure. The leg was cool and not tender, and the skin was thick, as in a case of myxedema.

In addition to the observations enumerated, there was slight limitation of the temporal fields of vision. The ocular fundi were essentially normal The disks, however, were somewhat oval, with the long diameter vertically situated. There was slight ocular motor weakness on the right side. The cranial nerves otherwise were normal. There was no nystagmus and no weakness of the arms or legs. The deep and superficial reflexes were normally active. The ears, nose and mouth showed nothing of interest. No abnormalities were noted in the neck.

Measurements of Legs

	Right Leg	Left Leg
Ankle	35 cm.	41 cm.
Calf (10 cm. below patella)........	44 cm.	46 cm
Calf (immediately below patella)...	45 cm.	45 cm.

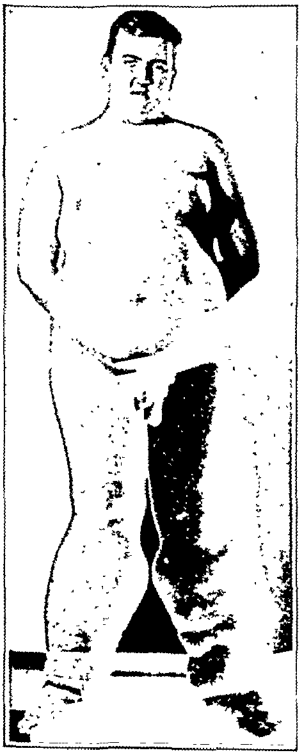

Fig. 2.—Appearance just before Kondoleon operation.

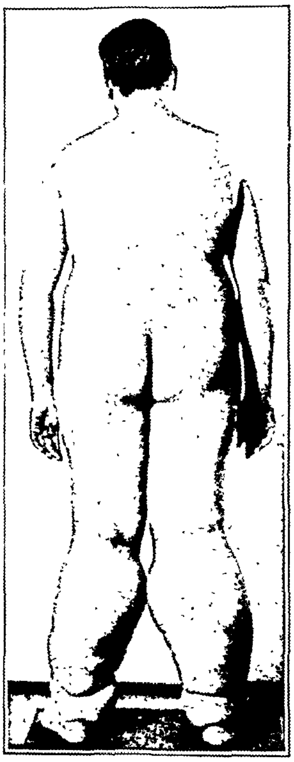

Fig. 3.—Posterior view of patient just before Kondoleon operation.

The heart was not enlarged. The pulse was occasionally intermittent. A soft systolic murmur was present at the apex. The lungs were clear. No tenderness was elicited in the abdomen, and the liver, kidneys and spleen were not palpable. The skeletal and lymphatic systems were normal.

The diagnoses were: (1) Milroy's disease; (2) Fröhlich's syndrome.

Laboratory Examination.—The results of the laboratory examinations may be thus summarized:

Microscopic examination of blood, negative. No filariae were seen. (Preparations made during the day and night.)

Urine, normal.

Chemical analysis of the blood: urea, 11; sugar, 65; sodium chloride, 427.

Dextrose tolerance, normal.

Roentgen examination of the skull: upright posterior clinoid and enlarged sella turcica; no erosion.

Basal metabolic rate, —15.

Perimetric examination, concentric limitation of visual fields.

Blood culture, negative.

teen cases are diagnosed as thrombo-angiitis obliterans and seventeen as arteriosclerosis. A record of the cases reported from this clinic is given in table 2. Two are classed as thrombo-angiitis obliterans and the remaining eighteen as arteriosclerosis. This gives a total of sixteen cases of thrombo-angiitis, with ten cases showing improvement and six failure. Our own slight experience with vein ligation in thrombo-angiitis obliterans has been disappointing. In the group of peripheral vascular disease due to arteriosclerosis with or without diabetes, nine patients are reported as improved and nine as unimproved. In the series here reported, eight patients are improved after a year or more, eight have had leg amputation and four have died within a year of operation without amputation. Of the living patients, half have shown a successful outcome. This result is modified by critical analysis. For example, it will be seen in table 2 that case 3 is classed as showing a good circulation and that the pulse of the dorsalis pedis and posterior tibial arteries is perceptible. Such a patient has gangrene from infection and not from circulatory deficiency and would recover with proper treatment of the local lesion. This satisfactory result should not be credited to vein ligation.

If this patient, the patient presenting gangrene of an amputation stump (case 2), and those who died within a year (patients 1, 4, 8, 18) are excluded, there remain fourteen for analysis. Of the latter, four are classed as having a poor circulation without pulsation in either the popliteal or the femoral artery. All were failures. Such unsuitable cases should have primary leg amputation. Of the remaining ten patients, who are classed as having a fair circulation with a pulsating popliteal artery, nine had gangrene of the extremity. Of these ten patients, four (40 per cent) had leg amputation within a year and six (60 per cent) have had a satisfactory result with full return of function. This group represents properly selected cases according to the present conception.

It is felt that this series gives a fair idea of what may be expected from vein ligation in diabetic or arteriosclerotic gangrene, for the following reasons: The patients were treated by six different surgeons; the status of the peripheral circulation in the patients reported was good, bad and indifferent, and, though the conservative treatment of the lesion did not result in septicemia or death in any instance, the mortality rate from other causes was about average for such a series.

Too much should not be expected of any one procedure in these cases. Vein ligation should be only a part of the treatment of the patient and of the local lesion. Its use in appropriate cases is of value and often definitely improves the peripheral circulation so that a good functioning foot is preserved.

SUMMARY AND CONCLUSIONS

1. In obliterative vascular disease of the extremities, operations on the blood vessels are justifiable but are essentially palliative since they do not affect the cause of the original disorder.
2. The effect of venous obstruction in the presence of arterial insufficiency makes it a desirable procedure in appropriate cases.
3. Thirty-one cases in which this operation was performed are collected from the literature and twenty additional ones, followed for a year or more, are reported.
4. Analysis of these fifty-one unselected cases shows that approximately half were benefited, while leg amputation was done in the remainder after a variable period of improvement.
5. A basis for selection of cases is given which creates three groups: (1) those which show a hopelessly damaged circulation, requiring leg amputation; (2) those which result from infection and require only treatment of the local lesion, and (3) those in which there is a fair circulation, with a patent popliteal artery but absent peripheral pulses, and in which conservative treatment including vein ligation should be given.
6. Analysis of the suitable cases shows that in 40 per cent leg amputation was needed within a year, while 60 per cent had a satisfactory result with return of function.
7. Vein ligation should be considered as only a part of the care of these patients. Its use in appropriate cases definitely increases the efficiency of the circulation of the extremity and helps to avoid leg amputation.

[9] Ho[illegible] H.: Persistent Hereditary Edema of the Legs, wit[illegible] Milroy's Disease, Quart. J. Med. **1**: 312, 1907.

Roentgen examination of the legs: enlargement of soft parts; no changes in bones.

Roentgen examination of the chest, negative.

Wassermann reaction, negative.

Electrocardiographic examination: sinus arrhythmia, left axis deviation; occasional ventricular premature contractions.

Course.—On the fifth day following admission to the hospital, a biopsy was done, a piece of skin being removed from the left thigh for microscopic and bacteriologic study. A culture from the operative incision showed the presence of hemolytic streptococci which were difficult to grow and impossible to transplant.

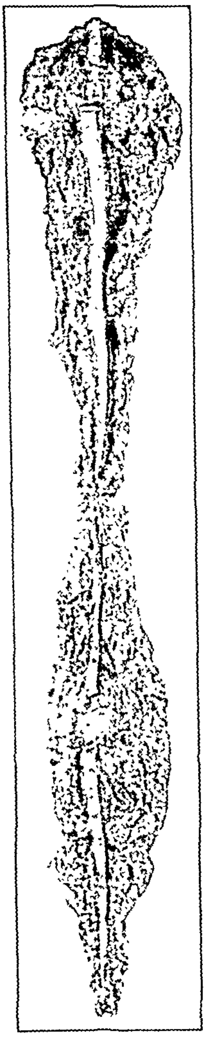

Fig. 4.— Specimen removed at Kondoleon operation.

On the twelfth day the patient suddenly had a chill with an elevation of temperature to 105 F. He complained of marked tenderness in the right leg, which was fiery red and much warmer than the left, in which the usual appearance persisted. Otherwise the physical examination at this time showed nothing of interest. A blood count showed 33,000 white cells with 90 per cent polymorphonuclear neutrophils.

Antistreptococcus serum given intracutaneously failed to produce local blanching; however, 100 cc. of this serum was given intravenously, and within twenty-four hours the temperature was normal, the local symptoms had practically disappeared and the white blood cells were 12,000.

Invariably, previous "acute attacks" had lasted for four days; but as to whether this apparently beneficial effect was a coincidence, the result of nonspecific protein administration or of other factors is uncertain.

Because of the low metabolic rate and obesity, thyroid extract was administered, but no improvement in the legs occurred. A Kondoleon operation was suggested, but the patient refused to give permission, and he was discharged to the outpatient department.

During the next two years the boy was seen from time to time, and definite progressive increase in the swelling of the legs, as well as increasing obesity, was noted (figs. 2 and 3).

Because of his economic status the purchase of suitable shoes and stockings became a serious problem. On account of difficulty in walking, an active occupation was impossible. As he was definitely mentally retarded, no sedentary position requiring ordinary mental capacity was obtainable. Finally the family and patient became desperate and requested that something be tried.

Dr. Mont Reid advised a Kondoleon operation in the hope of securing an anastomosis between the superficial and deep lymphatics of the leg. At the operation, which was performed on the right leg, a strip of skin, subcutaneous tissue and tensor fasciae latae was removed, the incisions starting at the anterior superior spine and extending to the ankle (fig. 4). The widest portion of skin in the specimen measured 12 mm. The incisions sloped outward and downward through very wet, "milky," subcutaneous fat and scar tissue, to the tensor fasciae latae in the thigh and to the deep fascia in the leg, the widest portions of these removed measuring 12 cm. A culture was taken from the incision, but no organisms were grown. Too brief a period has elapsed since operation to draw conclusions with regard to its success. Sistrunk[10] has reviewed the results of similar operations in his cases.

Pathologic Examination.—The first specimen to be examined was the small piece of skin removed from the patient's leg at biopsy in November, 1928. Sections were stained by the following methods: (1) van Gieson's acid fuchsin-picric acid, (2) hematoxylin-eosin, (3) Mallory's aniline blue, (4) Marchi's osmic acid, and (5) Verhoeff's elastic tissue stain. Microscopic examination (fig. 5) revealed a normal epidermis, directly beneath which there appeared to be a condensation of the superficial portion of the dermal papillary layer. With Mallory's aniline blue stain this portion of the dermis had a membranous appearance and was composed of fine collagen fibrils, which in some areas were undergoing hyalinization. No elastic tissue was found in this layer, and there seemed to be fewer capillaries than normal extending into the papillae. In the reticular layer, the heavy collagen fibers were somewhat spread apart by edematous fluid, but the edema was not nearly so marked here as in the deeper parts. The small groups of blood and lymph vessels, especially those of the subpapillary network, were surrounded by a considerable sprinkling of lymphocytes, which seemed to be more definitely related to capillaries and venules than to arterioles or larger vessels. Although the dermis was widened by the moderate amount of fluid present, there was also a definite increase in the number of collagen fibers, thus producing marked increase in the proportion of dermis to epidermis. The subcutaneous tissue was also much thicker than normal, being composed of large masses of edematous fatty tissue embedded in which were vessels and nerves. In some areas the stroma and fat cells were entirely absent, great pools of fluid being formed with no definite limiting boundaries (fig. 6). A few dilated lymphatics were seen, but much of the fluid occurred in spaces having no visible endothelial lining.

The second specimen to be studied consisted of a number of sections taken from various areas in the large piece of skin, subcutaneous tissue and tensor fasciae latae which was removed at operation (fig. 4). The same stains were used as on the preceding specimen. Microscopic examination revealed pathologic changes differing little from those in the biopsy sections just described. The epidermis was slightly thicker than in the earlier sections, but the papillary ridges were still well defined, and the membranous layer of collagen fibrils just beneath the epidermis was very sharply outlined. Although the edema of both the dermis and the subcutaneous tissues was considerably more marked than in the earlier sections, the active inflammatory changes, while still present, were in general much less marked. There were, however, a few venules in the subcutaneous areas which showed focal polymorphonuclear infiltration in their walls.

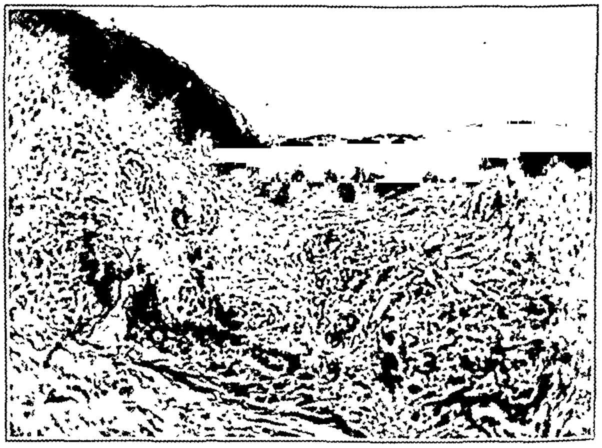

Fig. 5.—Section of epidermis and dermis showing condensation of superficial papillary layer and lymphocytic reaction in the reticular layer.

One small artery beneath the tensor fasciae latae showed very definite intimal sclerosis with narrowing of the lumen. The media of some of the arterioles in the sub[illegible]us areas seemed to be hypertrophied.

---

[10] Sistrunk, W. E.: Further Experiences with the Kondoleon Operation for Elephantiasis, J. A. M. A. 71: 800 (Sept. 7) 1918.

Marchi's method revealed no lipoid material in the pools of fluid previously described. The material in these spaces was colorless by all methods employed, with the exception of a faint pink granular appearance when eosin was used.

COMMENT

In order to determine whether the changes described occur in conditions other than Milroy's disease, sections of skin were collected from other patients, particularly those having edema of known etiology. So far, only autopsy specimens have been available, but these have all been taken within a few hours after death. Whether or not the inflammatory and other vascular changes that were found in our patient are characteristic of Milroy's disease can be determined only by studying other persons having the same disease. That they are not pathognomonic is certain, because they have been found in other conditions. The pools of fluid apparently outside vessel walls have so far not been found in sections from other conditions, including marked edemas of traumatic and cardiovascular origin. Also, in no other sections has so marked condensation of the dermal papillary layer been found. In the sections of skin showing edema of cardiovascular, traumatic and local obstructive origin, the epidermis has appeared to be thinned out and stretched, with flattening of the epidermal and papillary ridges. This appearance has been notably absent in all the sections from our case of Milroy's disease.

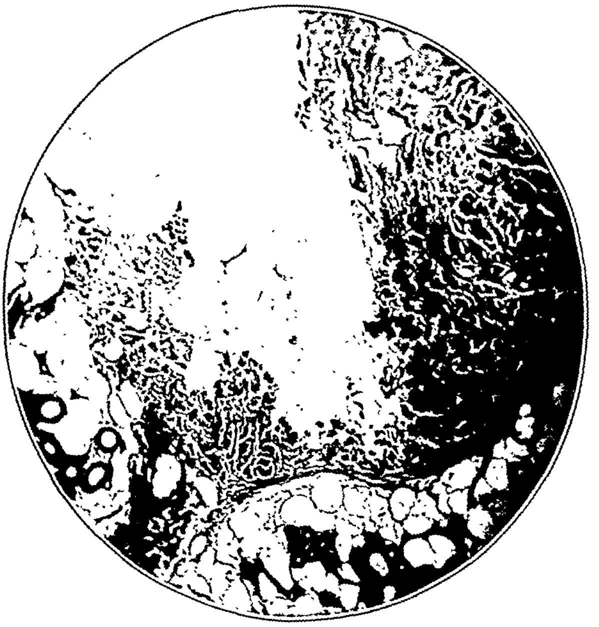

Fig. 6.—Section of subcutaneous tissue showing a large "pool" of fluid.

SUMMARY

1. A characteristic case of hereditary edema of the extremities has been studied for several years.
2. The pathologic alterations in the skin are described for the first time.

Cincinnati General Hospital.

The Goal of Science.—The aim of science has always been to find out the real facts, to avoid mere opinion and prejudice. By this aim and this method the scientific attitude is developed. It accepts the truth wherever it may lead, and places it above all doctrines and authorities.—Burnham, William H.: The Wholesome Personality, New York: D. Appleton and Co., 1932.

SUPPURATIVE PERICARDITIS

REPORT OF A CASE [*]

EDWIN M. MILLER, M.D.
CHICAGO

Suppuration within the pericardium is never primary. It may follow the occasional penetrating wound, as from a knife blade or a bullet;[1] it may appear as a metastatic abscess secondary to a general infection of the blood stream,[2] or, as most often happens, it may develop by direct lymphatic extension, generally from a suppurative focus within the mediastinum,[1] lung tissue or pleural space. Clinically, it is seen most commonly after pneumonia, and the pneumococcus is the prevailing organism.

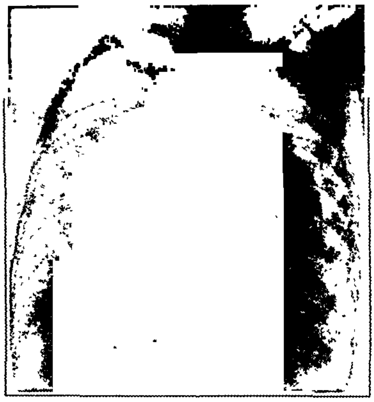

Fig. 1.—Appearance of chest immediately before surgical drainage of the pericardium.

The diagnosis in the early stage is not always easy. Clouded as they may be by the overshadowing observations of associated pathologic changes within the chest, the signs of a small accumulation of turbid fluid within the pericardial sac may be overlooked. As the amount of pus increases, however, and the sac becomes distended, the work of the heart becomes embarrassed and the clinical signs more distinct. The general picture of severe sepsis, the anxious pinched expression of the patient, the evidence of constant pain over the heart, the dyspnea, the cyanosis, the enlarged rounded area of cardiac dulness over which the heart tones are distant or, indeed, scarcely audible, together portray a clinical picture almost classic, leaving little to be added either by the aspirating needle or by the roentgenogram.

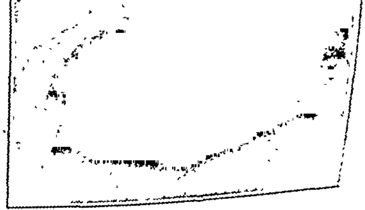

Fig. 2.—Appearance of chest three days after surgical drainage of the pericardium.

The prognosis varies with the cause but depends greatly on the treatment. Those cases which follow pneumonia are the most favorable, those secondary to a general sepsis the least. Left alone to follow the natural course, untreated cases are invariably fatal; with repeated aspiration, carried out not without considerable risk, 12 per cent perhaps may show recovery; by surgical drainage the mortality has been reduced to 50 per cent.

[3] Loucks, H. H.: Suppurative Pericarditis, Arch. Surg. **18**: 852 (March) 1929.

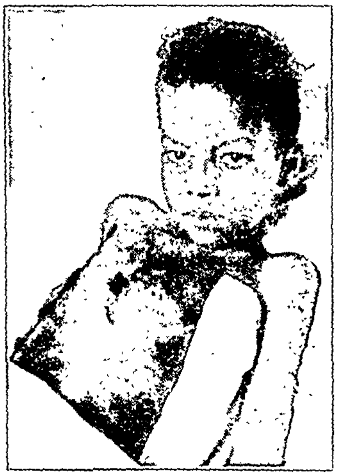

Fig. 3.—Patient three days after surgical drainage of the pericardium. Through the drainage tubes the cavity of the pericardium was irrigated with physiologic solution of sodium chloride.

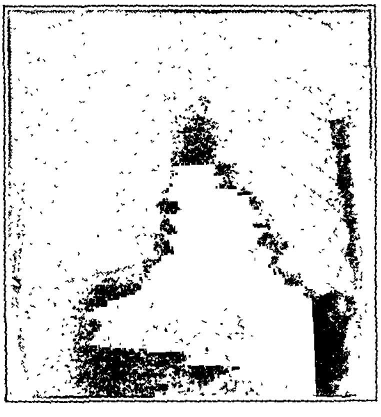

Fig. 4.—Normal appearance seven months after surgical drainage.

It is not necessary here to review the literature which has been gathered together since an infected pericardium was first successfully drained by Romero more than a hundred years ago, or to recount in detail the technic involved in the various methods of approach. Suffice it to say that during this period of time the feasibility of the principle of surgical drainage has become widely recognized and the basic plan of procedure generally accepted. The logical approach is, of course, from in front and is generally sufficient, yet the experience of Loucks teaches us that pocketing of pus may take place behind the heart, necessitating a second attack from behind. Whether one penetrates the sternum in the midline, as recommended by Shipley and Winslow,[4] or whether one enters the distended sac just to the left of its margin, as advocated by most physicians, matters not a great deal, so long as the operation can be quickly done and a sufficiently large opening made. Brooke is of the opinion that early drainage in cases secondary to acute osteomyelitis is most essential, even before the fluid contains frank pus. As to the matter of tube drainage and irrigation, opinions differ, but it is my personal belief that anchoring two soft rubber tubes to the margins of the opening and carefully irrigating the cavity at intervals with warm physiologic solution of sodium chloride not only is unharmful but greatly facilitates the rapid emptying of the accumulated pus. The suggestion of Dana,[5] who recently has written on the closed drainage of acute empyema cavities by substituting air for the pus evacuated, is very interesting. As applied to the case of suppurative pericarditis, this method might appear very attractive were it not for the positive danger involved in repeated needling so close to the heart.

REPORT OF CASE

H. L., aged 8, a Negro boy, admitted to the medical service at the Cook County Hospital, March 8, 1930, was acutely ill. The temperature was 101.2, the pulse 120 and respiration 138. The diagnosis made on examination was suspected bilateral pulmonary tuberculosis. A definite history could not be obtained. Over both sides of the chest, relative dulness was elicited and bronchovesicular breathing was heard with many moist fine crepitant râles. The heart was essentially normal. The abdomen was somewhat distended, tympanitic and tender. A diagnosis of diffuse bronchopneumonia was made. A roentgenogram (fig. 1), March 10, revealed a large rounded cardiac shadow with relatively clear lung fields and led at once to the suspicion of pericarditis with effusion. During the following two days the heart tones became muffled and distant, and aspiration revealed the presence within the pericardium of thick yellow-green pus, containing the pneumococcus. March 19, the patient was transferred to the surgical service.

As the boy came to the operating table, he appeared extremely sick and was apparently in great pain. Dyspnea, cyanosis and a bulging precordium were the marked symptoms. Under local anesthesia, with the patient in the sitting position, a 4 inch incision was made just to the left of the sternal margin, and the cartilages of the fifth and sixth ribs were resected so as to expose the bulging pericardium between the border of the sternum and the main trunk of the internal mammary artery. A gush of pus, as from a hose, shot into the air, and within a few seconds a pint or more of pus covered the field. The incision was then enlarged, the fingers were introduced about the heart, and no pocketing was noted posteriorly. The ends of two soft rubber tubes were anchored to the margins of the wound, and through these the cavity was gently irrigated with warm saline solution. Relief was immediate, and the boy left the table much improved. The postoperative course was practically uneventful. Irrigation was continued at frequent intervals, the acute symptoms rapidly subsided, and the amount of discharge steadily decreased. At the end of six weeks, the wound was practically healed and the boy was allowed to go home. His clinical progress and the changes in the roentgen observations are illustrated in figures 1 to 6.

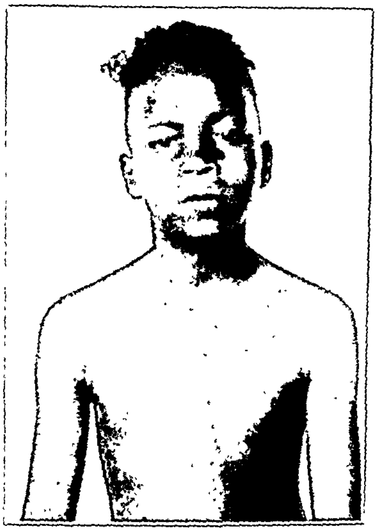

Fig. 5.—End-result one and one-half years after surgical drainage.

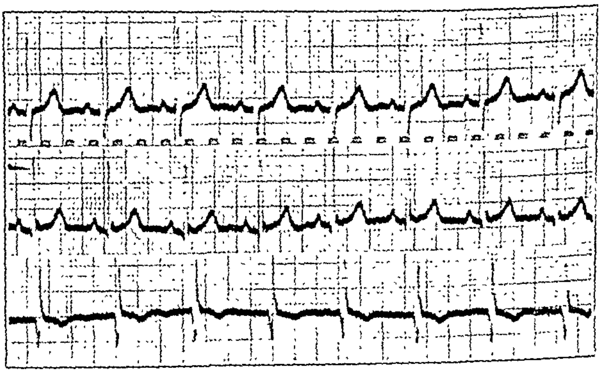

Fig. 6.—Electrocardiographic study by Dr. Clayton J. Lundy one and one-half years after surgical drainage of the pericardium.

Cardiac examination, July 22, 1931, by Dr. Clayton J. Lundy, showed a regular pulse rate of 82. There was a rather large

visible pulsating area in the fourth and fifth interspaces at the site of operation, just left of the sternum. The left heart border was 1.5 cm. to the left of the nipple line, which was about 9 cm. left of the midsternal line. The right heart border was just to the right of the left sternal border. The heart sounds were clear. The intensity of the second aortic sound was about equal to that of the second pulmonic sound. The systolic blood pressure was 118 and the diastolic 76 mm. of mercury. The lungs were normal. When the position of the patient was shifted from his back to his left side, the left heart border shifted to the left about 2 cm. When he was placed on the right side, the right heart border seemed unchanged. This conformed to the electrocardiographic estimation of shifting of the electrical axis, which was plus 50 degrees when the patient was on his back, plus 80 when he was on his left side, and plus 53 when he was on his right side. The electrocardiogram taken July 22, in addition, showed a diphasic Q-R-S$_1$, notched Q-R-S$_2$ near the base line, and a slurred Q-R-S$_3$. There was no clinical or electrocardiographic evidence of cardiac damage, and the adhesions after pericardostomy had not interfered with normal shifting of the heart's position when the patient turned on his left side, although there was some limitation of rotation when the patient turned on his right side.

ACUTE PYOGENIC INFECTION OF THE SPINAL EPIDURAL SPACE *

SAMUEL S. ALLEN, M.D.
AND
EDGAR A. KAHN, M.D.
ANN ARBOR, MICH.

Of the diseases involving the coverings of the spinal cord and the cord itself, acute pyogenic infection of the epidural space is comparatively infrequent. It is, however, a definite disease entity, and the histories, physical signs and laboratory observations of the various cases reported are strikingly similar. Acquaintance with the condition, making possible an early diagnosis, is of great importance to the patient; for, although the prognosis is quite poor, adequate drainage at the earliest possible date offers the best if not the only means of treatment.

If infection is known to be present in some other part of the body, the arrival at a diagnosis of the condition may be facilitated. But in cases in which this is not known to exist, diagnosis may be a difficult procedure. This is true especially in cases in which the body does not react in the usual way to an acute purulent process, or in which the infection is too early to be localized and not extensive enough to produce a well marked febrile state. As the cord symptoms are at first due only to mechanical pressure from without the dura, the early observations may be somewhat confusing and difficult to interpret. The end-result, of course, is a complete transverse lesion of the spinal cord.

Case 1.—V. M., a man, aged 25, had an attack of appendicitis eighteen months prior to his admission. An appendectomy was performed, and he was apparently convalescing nicely when a subphrenic abscess developed. He then had a septicemia, which was shown by positive blood cultures. The entire illness lasted four months, and several months before the onset of the present illness he was able to return to work. Two weeks before admission, he was seized with sharp pains in the right side of the chest, which were not relieved by strapping. Three days later he noticed numbness of both feet, which gradually extended up to his hips. This was accompanied by weakness of both legs, which resulted in complete paralysis within twelve hours. By this time the numbness extended well up the thorax, he was unable to void urine and had fecal incontinence.

Examination showed equal and regular pupils which reacted readily. The extra-ocular movements were normal. The ocular fundi showed considerable hyperemia. There was no facial weakness. The tongue protruded in the midline without tremor. There was some stiffness of the neck muscles. The biceps, triceps and supinator reflexes were normal. The abdominal musculature was rather tense and the abdomen distended. The umbilical reflexes were lost. There was a complete flaccid paralysis of both legs. Knee and ankle reflexes were absent, and plantar irritation caused no response. Sensation to pain was lost on either side to the level of the third thoracic segment, heat to the fourth segment and cold to the second. Loss of tactile sensibility extended up to the third segment.

Shortly after admission the temperature rose from 101.6 to 105. The leukocyte count was 5,000. A lumbar puncture was done which showed the presence of a complete subarachnoid block. The fluid was xanthochromatic and coagulated on standing. Roentgenograms of the spine showed normal alinement, contour and density of the vertebral bodies, with no change in the intervertebral spaces.

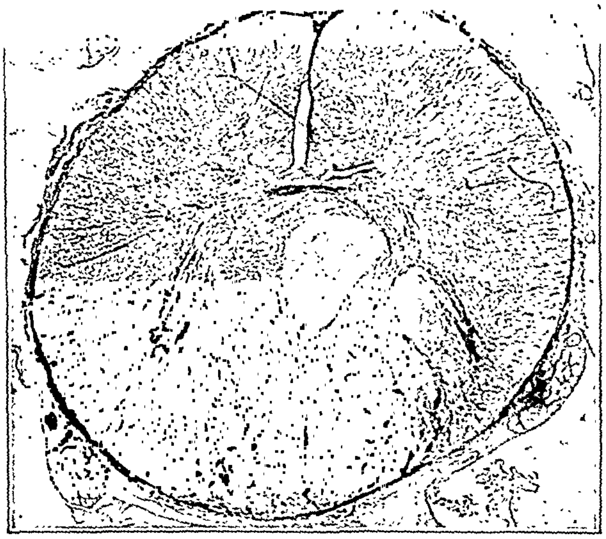

Fig. 1.—Section from lower thoracic cord. The posterior funiculi show considerable edema, and a small cystic area of degeneration is present posterior to the gray commissure. Hematoxylin-eosin stain; slightly reduced from a photomicrograph with a magnification of 50 diameters.

The history of the previous infection, the symptoms of pain followed by paralysis, and the marked degree of toxicity suggested the presence of an acute infection within the spinal canal, the lumbar puncture aiding in the diagnosis, and the upper limit determined by the sensory level. A laminectomy was done, centering over the fourth thoracic spine. Numerous abscesses, some large, others quite small, occupied the epidural space. The fat appeared red, and thick greenish pus oozed from its surface. The abscess formation extended upward to the second thoracic vertebra. More lamina were removed below, and the process was found to extend caudally to the first lumbar vertebra. The thick purulent exudate and necrotic fat were stripped from the surface of the dura, which appeared quite reddened. Although the greater portion of the pus was posterior to the dura, it was also seen to exude laterally along its surface in the lower thoracic region. The wound was irrigated thoroughly and the Carrel-Dakin method of treatment was used. Cultures of the pus showed Staphylococcus aureus.

The patient's condition did not improve following operation. About the fifth postoperative day, the wound began to show more purulent material than ever. The temperature continued in the characteristic septic course, and several times the patient was seized with severe chills. A blood culture was taken during one of these seizures, and a strain of Staphylococcus aureus was recovered from the blood stream. The patient's condition

---

* From the Department of Surgery, University Hospital.

became progressively worse, and he died on the fifteenth day after operation. Permission for a postmortem examination was not granted; therefore we do not know whether the infection had extended inward beyond the dura. There were, however, *no symptoms of a true leptomeningitis.*

Case 2.—H. D., a girl, aged 15, fell while roller skating four weeks prior to admission. At the time, she noticed some pain in the lower part of the back. Several days later, a sharp pain developed in the back, which radiated down both legs. Three days later she began to have difficulty in moving her legs and three days following this she was completely paralyzed, had retention of urine, and noticed numbness of both legs and of the entire abdomen. When admitted, she complained that the pain was quite severe and was becoming worse.

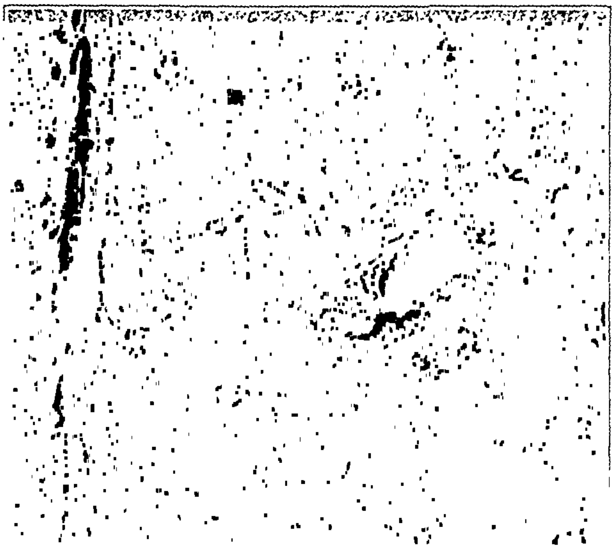

Fig. 2.—Small area of cord undergoing necrosis. The same area may be seen in the lower left hand corner of figure 1. Hematoxylin-eosin stain; slightly reduced from a photomicrograph with a magnification of 200 diameters.

Examination showed equal and regular pupils, which reacted readily. The extra-ocular movements were normal and there was no nystagmus. No evidence of facial weakness was present and there was no disturbance of sensation of the face. The tonsils were small and showed no evidence of infection, and the oral hygiene was good. Examination of the nose and ears gave no evidence of infection. The biceps, triceps and supinator reflexes were normal. There was complete loss of sensation below the level of the seventh thoracic segment. The umbilical reflexes were absent. There was a complete flaccid paralysis of both legs, with loss of the tendon reflexes. Plantar irritation gave no response. There was no cervical rigidity, and Kernig's sign was negative.

The temperature at the time of admission to the ward was 100.5, the pulse 110, and the respiratory rate 24. The leukocyte count was *30,000. Repeated dry taps were obtained* when lumbar punctures were attempted. Roentgenograms of the entire spine showed nothing abnormal.

A diagnosis was made of spinal epidural abscess in the region of the fifth thoracic vertebra. A laminectomy, centering over this area, was performed. A greenish white, purulent exudate oozed from the surface of the epidural fat. This was seen to extend upward as high as the fourth thoracic vertebra and to involve the remaining epidural tissue caudally, necessitating the removal of the laminae as far as the first lumbar vertebra. The thick purulent material was thoroughly removed and the remaining epidural tissue carefully stripped from the surface of the dura. A rather mild pachymeningitis was present. At the level of the ninth thoracic vertebra, pus was seen oozing from the anterior part of the canal. The dura was retracted laterally, and considerable pus escaped. Acriflavine packs were placed into the wound, which was allowed to remain wide open. Cultures of the pus showed Staphylococcus aureus.

Following operation, the patient's temperature continued elevated, but assumed a septic curve. Three days later, the acriflavine packing was removed and the wound appeared clean. On the eighth postoperative day the patient had a *chill, following which her temperature rose to 106.* Several similar chills followed, but blood cultures taken during these failed to show any growth. Her condition became progressively worse, and she died one week later.

At autopsy, considerable pus was found in the spinal canal from the seventh cervical to the first lumbar vertebra. From the ninth to the twelfth thoracic vertebra, the pus was present in the anterior as well as the posterior part of the canal. The dura was covered with a fibrinopurulent exudate and was greatly thickened throughout the entire thoracic region. When the dura was opened, the cord was found to be quite swollen, but no pus was present. The leptomeninges were matted together, thus completely obliterating the subarachnoid space. The cord was definitely softened, the softening being most marked in the lower thoracic region.

Microscopic examination of the cord at various levels showed extensive degeneration of the tracts most marked in the posterior columns in the lower thoracic segments. The amount of edema was striking. Immediately posterior to the central canal was a small cystic area, containing broken-down cord substance but no inflammatory cells (fig. 1). Other smaller areas of necrosis were present, in which were seen many newly formed vessels (fig. 2), and in the cord surrounding these areas were collections of gitter cells. In some portions of the posterior funiculi, there was a honeycomb appearance due to the marked edema (fig. 3). The nerve cells were badly degenerated, especially in the anterior horns (fig. 4).

Case 3.—H. W., a man, aged 30, in whom a furuncle on the neck developed three weeks prior to admission, was responding well to treatment when he began to have severe pain in the back. The pain was sharp and radiated upward to the midthoracic region and downward to the scrotum and thighs. The pain continued, and one week after its onset he was taken to a small hospital near his home, where a lumbar puncture was done, but no fluid was obtained. The following day the pain became more severe than ever, and on the succeeding day his legs became paralyzed and he was unable to void. The pain then subsided, and he noticed numbness of the legs and abdomen. Three days later, he was admitted to University Hospital. The temperature was 104.6, and the pulse rate 160.

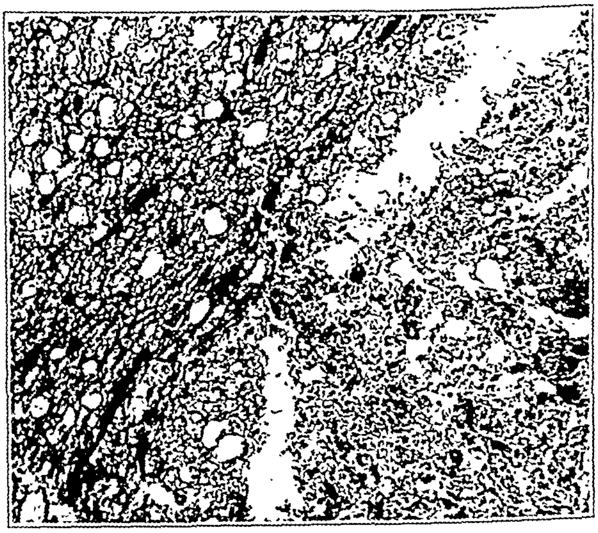

Fig. 3.—Portion of cord adjacent to small cystic area of degeneration, showing honeycomb appearance of posterior column due to marked edema; phosphotungstic acid hematoxylin. Slightly reduced from a photomicrograph with a magnification of 200 diameters.

Neurologic examination showed the right pupil to be larger than the left. Ophthalmoscopic examination revealed a neuroretinitis in each eye. There was no paralysis of the face or tongue. The tendon reflexes of the upper extremities were normal. The abdominal and cremasteric reflexes were absent. There was a flaccid type of paralysis of the legs, with loss of all reflexes. There was a sensory level extending to the seventh thoracic segment. Just above this level was a zone of hyperesthesia, about 2 cm. in width.

The urine contained many pus cells to the low power field. Blood examination showed a slight leukocytosis of 12,200. Roentgenograms of the spine demonstrated normal contour, alinement and density of the vertebrae. A lumbar puncture was not attempted.

A diagnosis of epidural abscess was made, and the patient was immediately prepared for operation. It was now four days since the onset of the paralysis, and the condition of the patient was quite grave; but it was believed that operation offered him his only hope. A laminectomy was performed, and the diagnosis was confirmed. An enormous amount of pus was present in the epidural space, producing considerable pressure on the dura. Cultures later showed Staphylococcus aureus. The infection extended from the fourth to the eleventh thoracic vertebra.

The postoperative period was more or less uneventful. The temperature continued elevated for the first week and then gradually became normal. Three weeks after operation the sensory level was at the tenth segment, but there was no change in the paralysis. His course has since remained stationary. We doubt whether movement will ever return. A retention catheter is necessary and urinary antiseptics are employed. The urine is remaining remarkably free from infection.

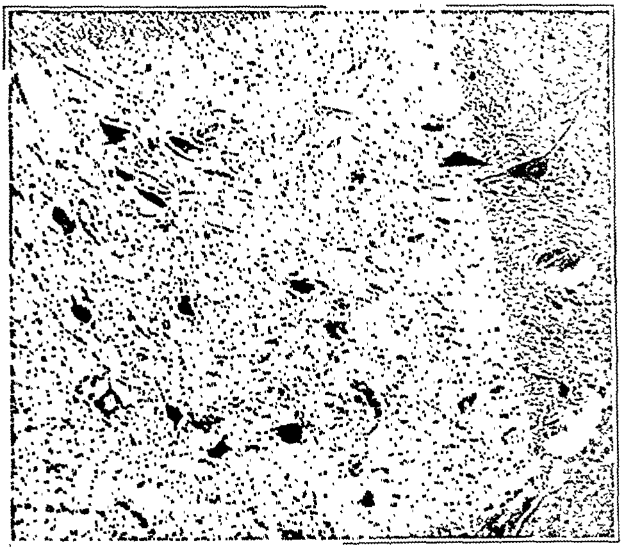
The relative infrequency of the disease is well demonstrated by the fact that Schmaltz[1] was able to collect [illegible] forty-three cases from the literature up to 19[illegible] Dandy[2] collected a series of twenty-five cases. Cases have since been reported by Hassin,[3] Veraguth and Schnyder,[4] Sittig,[5] MacDonald[6] and Wei Yu Lin.[7]

Dandy points out that the usual history of infection of the epidural space is acute severe pain in the back, along the course of the spinal nerves or in the legs, followed by paralysis of the lower extremities within a few days after the onset. This is very similar to the histories of our cases, although the paralysis in case 3 was a little slower in appearing. The pain is no doubt due to irritation of the posterior nerve roots. Elsberg[8] states that the symptoms of transverse myelitis are the result of a local interference with the circulation of the cord and a toxic softening of the cord tissue, rather than of mechanical pressure from without. This is shown quite well in our examinations of the cord in case 2. In the gross, the cord was greatly swollen and in some areas softened to such an extent that it was difficult to section. In these regions, no surface vessels were seen. Microscopic examination showed considerable destruction of both white and gray matter. The most extensive degeneration was in the posterior columns immediately underlying that portion of the dura which showed the greatest reaction to the infection. The effect on the anterior horn cells over so many segments accounts for the flaccid type of paralysis, which, on its appearance, aids greatly in arriving at a correct diagnosis.

That the infection is usually of a secondary nature is shown by Schmaltz's collection of cases. In Dandy's series, however, three of the cases were due to primary infection within the epidural space. One of our cases was undoubtedly of a metastatic nature, one was rather questionable, and in the other no evidence of infection elsewhere in the body could be found at autopsy.

Cultures of pus were made in seventeen of Schmaltz's cases, and in fifteen of these some form of staphylococcus was found. Staphylococcus aureus was the micro-organism isolated from the pus in each of our cases, and in case 1 it was recovered from the blood stream.

The conditions most likely to be confused with epidural infection are poliomyelitis, leptomeningitis, abscess of the spinal cord and tumor of the spinal cord. Poliomyelitis may be ruled out by the presence of a sensory level and of a subarachnoid block. Lumbar puncture, with examination of the fluid, is usually sufficient to eliminate the second possibility. As to abscess of the spinal cord, the simultaneous appearance of the sensory and motor symptoms certainly suggests the presence of an intramedullary lesion, while pain, appearing several days before the onset of the paralysis, is in favor of extradural involvement. A spastic and not a flaccid type of paralysis would be expected in the case of spinal cord tumor. The severe febrile state would also be absent. Of course, these points of differentiation are merely generalities, as the diagnosis of the localization and nature of lesions of the spinal cord is very often an extremely difficult matter. And aside from an academic standpoint, a mistaken diagnosis of abscess or tumor of the cord is of no great import, as immediate laminectomy, on the sudden appearance of paralysis, is certainly indicated.



[illegible] horn in lower thoracic region, showing degeneration of [illegible]. Nissl stain; slightly reduced from a photomicrograph with a magnification of 200 diameters

From the onset, the disease assumes the character of a profound toxemia. The only method of combating the infection is, perhaps, operation with adequate drainage of all the tissue involved. As the process is always quite extensive, it requires the removal of many laminae. The greatest involvement is in the midthoracic region, posterior to the spinal nerve roots. The infection in two of our cases, however, was seen to extend into the anterior part of the spinal canal.

Following operation, the treatment of the wound depends entirely on the method most favored by the

surgeon. Needless to say, the prognosis is quite poor, regardless of how early a diagnosis is made and how soon thereafter a laminectomy is done. Very few recoveries have been reported. The cord changes lead one to believe that unless operation is employed early in the course of the disease, the damage to the cord will be irreparable. This is only too well illustrated by our last case.

University of Michigan Medical School.

ELLIPTIC HUMAN ERYTHROCYTES *

GARNETT CHENEY, M.D.
SAN FRANCISCO

Abnormal shapes of human erythrocytes are generally associated with an anemia indicative of some disease affecting the hematopoietic system. In a few rare instances, elliptic and rod-shaped red blood cells have been noted in perfectly normal individuals with otherwise normal conditions in the blood. Such oval cells have received scant attention in the literature. The first report by Dresbach[1] appeared in 1904. Up to 1929, only seven references[2] to the condition were available. These included only fifteen cases, but the hereditary transmission of these bizarre erythrocyte forms was appreciated. In 1929, twelve cases were reported[3] occurring in three generations in a family with sixteen members. In 1931, Lawrence[4] reported four additional cases, and two as yet unpublished cases have recently been studied.[5]

As only thirty-three instances of elliptic erythrocytes have been noted in mankind as a presumably nonpathogenic observation, the present study of fourteen additional cases, all in three generations of one family, may add materially to the knowledge of this most interesting subject, particularly as the condition is commonly confused with sickle-cell anemia.

REPORT OF CASES

Tony P. was the first member in his family to come under observation. He had a high percentage of elliptic erythrocytes, and, as he remained in the hospital over one year and afforded abundant opportunity for study, his case will be described in some detail.

Tony P., a man, aged 39, an Italian laborer, entered the hospital on account of a generalized psoriasis. His father and mother were born in Palermo, Italy, and remained there. They were always well and strong. His father died of malaria, at the age of 48. His mother died at the age of 59, following a fall from a window. Three brothers and two sisters are living and well; one brother died, at the age of 35, of double pneumonia. The patient had come to the United States at the age of 5 years, and he did not remember any illnesses except a fissure in the anus, which had been operated on three years previously. For several years he had had attacks of indigestion and of pain in the right side. He had had psoriasis for ten years, which had spread from the extremities to the trunk, neck and scalp. Physical examination was essentially negative except for the generalized skin lesion and some tenderness in the right upper quadrant of the abdomen.

The urine, the stool, the blood count and the gastric analysis were not remarkable. The blood Wassermann reaction was negative. A basal metabolism test was plus 21. A gastro-intestinal x-ray series showed a deformity of the duodenal cap, and a gallbladder visualization showed a poor concentration of the dye in the gallbladder. Both biliary tract disease and duodenal ulcer were suspected, and both were subsequently demonstrated at operation.

While doing the routine blood count, the laboratory technician[6] noted elongated cell forms in the red cell counting chamber, and further studies of the blood were made. The bleeding time was four minutes. The coagulation time was two and one-half minutes. There were 0.8 per cent reticulocytes and 443,260 platelets per cubic millimeter of blood. The icteric index was 6, and a fragility test of the red corpuscles showed complete hemolysis at 0.33 per cent salt solution. The rate of sedimentation of the erythrocytes was also normal. Differential counts, as shown in the accompanying table, were done on wet and on dry preparations (fig. 1) of the patient's blood in order to determine the percentage of oval forms. Sealed wet preparations kept for two days and observed frequently showed no changes in the shape of the cells. A bone marrow showed the morphologic structure of the cells to be no different from that usually seen.[7]

Blood Studies of the Tony P. Family

41	Tony	9	Single	4,800,000	88	0	0	IV

The patient's son proved to have the same unusual oval erythrocytes in both wet (fig. 2) and dry preparations of his blood, and it was decided to investigate all the members of the family as far as possible.

The relationship of the patient's family and the incidence and transmission of the unusual morphologic appearance of the red blood cells are shown in figure 3. Of the patient's living relatives, one married brother resides in New York and one married sister in Buenos Aires, so that their families could not be studied. Thirty-seven descendants of his parents are included in the family tree, and four descendants of his mother's sister. Three of four members of the first generation show unusual erythrocyte forms; nine of twenty-five of the second generation, and two of eight of the third. Of the fourteen positive cases, four were in females and ten in males.

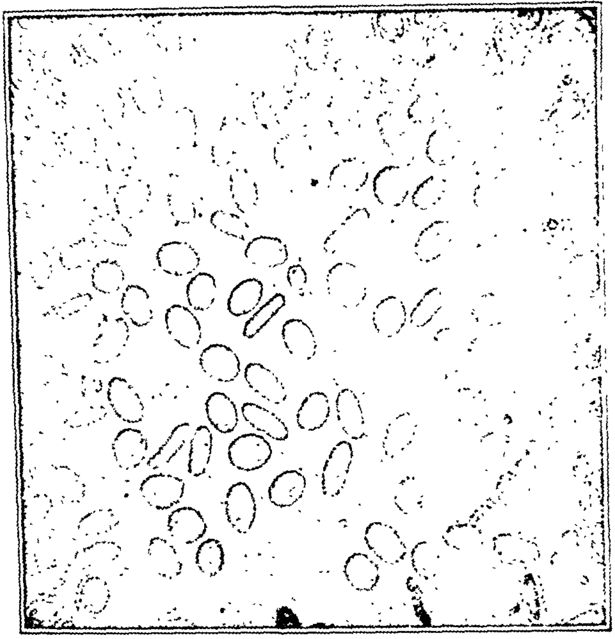

Fig. 1.—Elliptic erythrocytes seen on dry film in examination of blood of Tony P.

The changes in the blood are presented in the accompanying table. All the red blood cell counts, the hemoglobin estimations, the differential red cell counts and the blood typing were done by one technician, either at the hospital or, as in most instances, at the patient's home. All the subjects examined were in good health except Lena P., who was apparently pregnant and showed a slight anemia, baby Gloria C., who was convalescing from diphtheria, baby Raymond C., who had just left the hospital with anemia of unknown cause, and Dora C., who had whooping cough. It is worthy of note that none of the positive cases showed any definite anemia and that they occured in blood groups II, III and IV. There were only two instances of group I in the forty-one cases typed. An attempt was made to differentiate the abnormal red cell forms from the round ones in both the fresh and the dry preparations by microscopic observation. As the difference between a perfectly round cell and a very slightly oval one is impossible to detect accurately without measuring all the cells,[5] the percentages of normal and of abnormal forms present are but rough estimates, although based on repeated counts. The differentiation between an oval and a rod-shaped cell presented the same difficulties, as all intermediate forms were noted. A few truly rod-shaped and filiform cells were observed in nearly all the cases. In several instances the differential counts on the wet preparations were repeated the next day and proved to be essentially the same. The difference in the frequency of abnormal cell forms in the wet and the dry preparations has not been stressed previously, and the apparent increase of normal forms in the dry smears may be real or may be due to an alteration of the shape of the cell by the process of fixation, or, possibly, to the fact that the shifting positions of the floating cells in wet preparations make a slight ellipticity more apparent.

HEREDITARY ASPECTS

Since Dresbach's[1] original observation in 1904, the hereditary character of elliptic human red corpuscles has been suspected, and it is now firmly established. It has been demonstrated in only three successive generations of one family, although it is probable that it must have occurred in one or the other of the parents of Tony P., which would establish its incidence in at least four generations. His family demonstrates that the condition may be transmitted by either the male or the female, but it seems likely that it must be present in a parent in order to be transmitted to the offspring. This is strongly suggested by the fact that one brother, one niece and one nephew of Tony P. who had normal red cells had an aggregate of nine children all having normal cells. Also, all members of the family with abnormally shaped erythrocytes transmitted this characteristic to one or more of their offspring. Direct transmission is then common, while indirect transmission has not been proved.

Under such circumstances it is difficult to see why the condition is so rare. It is likely that it is often overlooked. Whether or not it is definitely transmitted according to the mendelian law cannot be stated, when but two family trees have been studied, each representing only three generations. However, from this very limited analysis it is strongly suggested that the trait of elliptic red cells is transmitted as a simple mendelian dominant. This cannot be settled until other large families are studied throughout several generations. Although there are as yet only eight individuals available for study in the most recent generation of the Tony P. family, two of whom show abnormal red cells, there are great potentialities for a far larger number. The data are as yet insufficient to determine whether successive generations show a decreasing percentage of abnormally formed cells or whether the degree of the ellipticity of the cells is diminishing. It would be helpful to study the branches of the family in New York and in Buenos Aires.

Elliptic erythrocytes are not limited to any race, in contradistinction to the generally accepted fact that sickle-cell anemia occurs only in individuals with Negro blood. Oval red corpuscles have occurred in Americans of Dutch, Italian and Scotch-Irish descent; in Germans, Italians, Russian Jews, American Negroes, and in an Austrian mulatto. The condition has not been reported in the oriental or South Sea races.

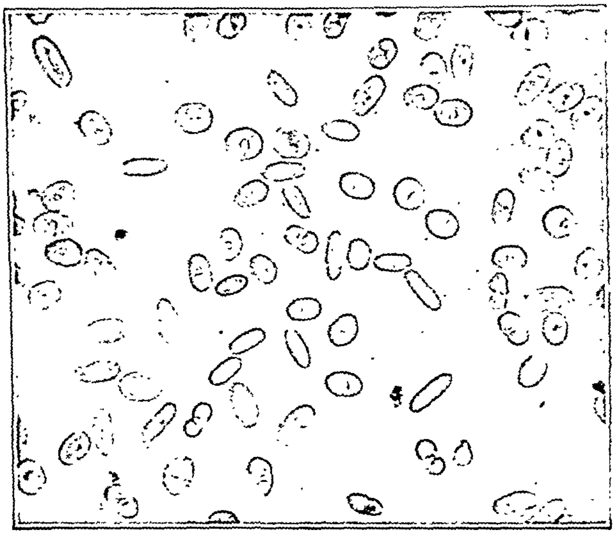

Fig. 2.—Elliptic erythrocytes seen on wet preparation in examination of blood of son of Tony P.

---

[5] A separate report will be made on the index of ellipticity of the red cells.

RELATIONSHIP TO ANEMIA

Recent reports[9] suggest a relationship between elliptic erythrocytes and anemia. There does not seem to be any sound basis on which to assume any such relationship. With the exception of Warren and Adam's family, including twelve positive cases of oval red cells, only five cases of anemia have occurred in the thirty-five remaining cases, and in four of these there were other causes for the anemia (gallbladder disease, with sepsis, menorrhagia, syphilis, diabetes and tuberculosis). The fifth case (Lawrence,[4] case 2) was that of an old Jewish laborer with 3,950,000 red corpuscles and 45 per cent hemoglobin. No etiologic diagnosis is recorded.

In the family of twelve individuals, some of the red cell counts are certainly low,[3] but in only two instances, except for the original patient, are the hemoglobin estimations (Sahli) below 83 per cent. As in all the other blood examinations suggesting anemia, the color index is well over 1; it seems probable that a further check on the red cell estimations might show them more compatible with the hemoglobin readings and, consequently, normal. No clinical investigations were made on the two individuals with both low red blood cell counts and low hemoglobin determinations, so that there may well have been adequate causes for the anemia. The original patient was a young woman of the type in whom quite marked anemias of unknown etiology not infrequently occur, and it seems probable that the unusual morphologic appearance of her red corpuscles is not related to the anemia.

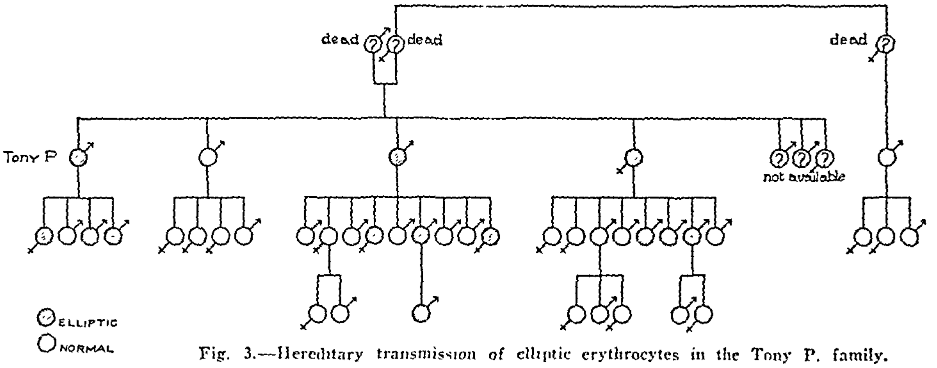

Fig. 3.—Hereditary transmission of elliptic erythrocytes in the Tony P. family.

Because of the bizarre forms of the erythrocytes, the blood picture in cases of elliptic red cells has been confused with that of sickle cell anemia, and it has recently been suggested that a relationship between the two conditions should be considered.[3] However, they are readily differentiated, both on clinical grounds and by the changes in the blood. The two conditions are hereditary, but here their similarity ceases. In contradistinction to the benign condition of elliptic erythrocytes, the disease of sickle-cell anemia has the following characteristics: It occurs only in Negroes; it is associated with anemia and with ulcers on the legs, and the sickle form of the red cells is progressively increased on standing in sealed wet preparations. Also, the typical sickle and crescentic cells are common in cases of sickle-cell anemia, while the rest of the red corpuscles are usually round. This is in sharp contrast to the picture in which elliptic cells are seen; here there are a series of transitional forms from the round red cells to such extremely elliptic forms that they may be designated as rod shaped. Only an occasional bent or sickle form appears, and even in these the ends of the cells seem rounded rather than pointed. Although a few individual cells may seem quite similar in the two conditions, morphologically the complete blood pictures are not to be confused, particularly when it is noted that in one "sickling" typically occurs and in the other it typically does not.

On the whole there does not seem to be sufficient evidence to associate oval red cells with any form of anemia or to look on the condition otherwise than as rare and curious, without any untoward effect on human health.

HEMATOLOGY

Human oval red corpuscles are biconcave ellipsoids which maintain a constant form under most conditions. They are quite similar to the erythrocytes of the camel as described by Loo,[10] which are normally ellipsoid although not constantly biconcave. The human cell may vary in size from one with a slightly narrower width and a slightly greater length than the diameter of a normal round cell to a rodlike cell with a width of 3 microns and a length of 13 microns. When human oval red cells are repeatedly washed with isotonic salt solution, or stand in a sealed wet preparation at room temperature for longer than seventy-two hours, or have pressure applied to them, many of them assume a circular or a spherical form.[5] Although their incidence in human blood is never 100 per cent, it is characteristic that the proportion of nondiscoid forms remains constant under normal conditions and never increases on standing, as in sickle-cell anemia. Repeated differential counts on the same patients over long periods of time are essentially the same. The ellipticity is not altered by changes in incubator temperature,[11] by single washings of salt solution, by the addition of normal blood serum after the cells have been washed, or by hypertonic salt solution. In hypotonic salt solution some of the cells appear to become circular before hemolysis occurs.[12] Terry has noted oval red cells in the heart's blood at autopsy and in the serum expressed from blood clot, and Huck and Bigalow identified th patient's oval cells in the recipient of a blood transfusi when their patient was the donor. Washed, normal shaped human erythrocytes remain unaltered wh introduced into the serum of a person whose who blood contains a large percentage of elliptic red co puscles.

Considerable interest has centered about the microscopic examination of the bone marrow in order to determine whether the elliptic cell forms could be identified before the corpuscles entered the blood stream. The sternum has been punctured in three cases for this purpose, nothing unusual being noted; so it seems evident that the bone marrow appears normal in individuals whose blood contains oval erythrocytes.

There is no evidence of increased blood cell hemolysis as the serum bilirubin determinations are normal, and fragility tests show that the resistance of the oval red cells to salt solution is normal. Reticulocyte counts,

On the whole there does not seem to be sufficient evidence to associate oval red cells with any form of anemia or to look on the condition otherwise than as rare and curious, without any untoward effect on human health.

HEMATOLOGY

Human oval red corpuscles are biconcave ellipsoids which maintain a constant form under most conditions. They are quite similar to the erythrocytes of the camel as described by Loo,[10] which are normally ellipsoid although not constantly biconcave. The human cell may vary in size from one with a slightly narrower width and a slightly greater length than the diameter of a normal round cell to a rodlike cell with a width of 3 microns and a length of 13 microns. When human oval red cells are repeatedly washed with isotonic salt solution, or stand in a sealed wet preparation at room temperature for longer than seventy-two hours, or have pressure applied to them, many of them assume a circular or a spherical form.[5] Although their incidence in human blood is never 100 per cent, it is characteristic that the proportion of nondiscoid forms remains constant under normal conditions and never increases on standing, as in sickle-cell anemia. Repeated differential counts on the same patients over long periods of time are essentially the same. The ellipticity is not altered by changes in incubator temperature,[11] by single washings of salt solution, by the addition of normal blood serum after the cells have been washed, or by hypertonic salt solution. In hypotonic salt solution some of the cells appear to become circular before hemolysis occurs.[12] Terry has noted oval red cells in the heart's blood at autopsy and in the serum expressed from a blood clot, and Huck and Bigalow identified their patient's oval cells in the recipient of a blood transfusion when their patient was the donor. Washed, normally shaped human erythrocytes remain unaltered when introduced into the serum of a person whose whole blood contains a large percentage of elliptic red corpuscles.

Considerable interest has centered about the microscopic examination of the bone marrow in order to determine whether the elliptic cell forms could be identified before the corpuscles entered the blood stream. The sternum has been punctured in three cases for this purpose, nothing unusual being noted; so it seems evident that the bone marrow appears normal in individuals whose blood contains oval erythrocytes.

There is no evidence of increased blood cell hemolysis as the serum bilirubin determinations are normal, and fragility tests show that the resistance of the oval red cells to salt solution is normal. Reticulocyte counts, platelet counts, bleeding time, clotting time, and rate of sedimentation are likewise normal. When the blood is typed according to the four recognized groups, as shown in Tony P.'s family there is nothing to suggest that the type of blood has any influence on the ellipticity of the erythrocytes. Studies of the white blood corpuscles show that they are normal.

SUMMARY

1. Up to the present time, cases presenting human elliptic erythrocytes have been very rarely reported. It seems probable that they are more common than the meager literature indicates.

2. The hereditary transmission of such unusual red cell forms is emphasized by a report of a family including forty-one members in three generations, fourteen of whom show this bizarre structure in the blood. The transmission is probably by a simple mendelian dominant.

3. Although this condition has been associated with secondary anemia and with sickle-cell anemia, there is insufficient evidence to justify any such relationship.

4. Aside from the unusual erythrocyte forms, there is nothing else remarkable in studies of the blood or of the bone marrow.

5. Elliptic human erythrocytes represent a departure from the round forms usually found and are not in themselves indicative of any disease, but are an inherited characteristic.

RHEUMATOID (INFECTIOUS) ARTHRITIS AND ACUTE RHEUMATIC FEVER

THE DIFFERENTIAL DIAGNOSIS *

A. M. MASTER, M.D.
AND
HARRY JAFFE, M.D.
NEW YORK

Acute rheumatic fever and rheumatoid (infectious) arthritis are often indistinguishable clinically,[1] particularly at the onset. They may both start acutely with an infection of the upper respiratory tract or with epistaxis. A moderately high temperature, chilliness, perspiration, prostration, spreading and transitory involvement of joints, acutely inflamed joints, leukocytosis and anemia are seen in the two conditions. Furthermore, the spleen and lymph nodes may be enlarged in each. Even the subcutaneous nodule,[2] hitherto considered to be one of the most characteristic phenomena of acute rheumatic fever, is definitely observed in rheumatoid (infectious) arthritis and its incidence[3] reported with increasing frequency by those who search for it. The sedimentation rate, too, no longer serves as a distinction, for the two conditions have been found to present increased rates of sedimentation of the red blood cells.[4]

Although in recent years numerous pathologic, bacteriologic and immunologic investigations[5] have increased our knowledge of the two diseases, they have perhaps created more difficulty in their differentiation. The observations have been so similar that the two diseases have been considered either manifestations of the same process,[6] or a strong relationship between the two has been considered. It is not our intention to deny or affirm these views; our work shows that in rheumatoid (infectious) arthritis the heart is minimally involved, whereas in acute rheumatic fever it is maximally involved.

For the last eighteen months an electrocardiographic study has been made on hospital patients with acute arthritis. There were seventeen patients discharged with the diagnosis of rheumatoid (infectious) arthritis, and sixty-three patients discharged with the diagnosis of acute rheumatic fever. In the rheumatoid (infectious) arthritis group there were nine males and eight females. The average age was 36 years; the range was from 13 to 53 years. The average hospital stay was fifty-three days. In the acute rheumatic fever group there were thirty-six males and twenty-seven females. The average age was 26 years, the youngest 13 years and the oldest 56 years. The average hospital stay was forty-four days.

Summary of Observations in Eighty Cases

	Rheumatoid (Infectious) Arthritis	Acute Rheumatic Fever
Cases	17	63
Average age	36 yrs.	26 yrs.
Males	9	36
Females	8	27
Average hospital stay	53 days	44 days
Tachycardia	35.3%	68.3%
[illegible]	23.5%	20.8%
[illegible]	29.4%	22.4%
[illegible]	0	9.6%
Auricular premature beats	0	9.6%
Ventricular premature beats	0	4.8%
Nodal rhythm	0	1.6%
Nodal tachycardia	0	1.6%
Inteference sinus and auriculoventricular nodes	0	3.2%
Auricular fibrillation	0	3.2%
Auricular flutter	0	3.2%
P-R 0.20 second	5.9%	12.8%
P-R over 0.20 second	11.8%	32 8%
Dropped beats	0	4 8%
R-S-T changes	0	84 8%
T wave inversions	0	40 0%
T_3 changes	0	8.0%
Change voltage Q-R-S	0	14.3%
Q-R-S changes	0	6.4%
Large Q_3	0	9.6%
R. A. D.	0	3.2%
L. A. D.	0	11.2%
P wave changes	6.7%	12.8%

The electrocardiograms were taken daily from the day of admission to the day of discharge.[7] The accompanying table summarizes our observations. The rheumatoid (infectious) arthritis changes can be reviewed quickly as the electrocardiographic observations were meager (figs. 1 and 2). There were six cases with tachycardia, i. e., rates above 100 per minute. Not once, however, was the rate above 120 per minute. Bradycardia, i. e., a heart rate below 60 per minute, was observed four times. A sinus arrhythmia was seen in five individuals. The auriculoventricular conduction time (P-R interval) increased from 0.16 to 0.20 second in one man, and to 0.21 second in another patient. In a third, the figure was unvaryingly 0.21 second, so that it is doubtful whether this faulty conduction may be ascribed to his disease.

[7] We consider daily tracings absolutely essential when studying acute diseases, because the abnormality may vary from hour to hour and from day to day. No digitalis or quinidine was ever prescribed; no drug was given that would itself produce changes in the electrocardiogram. The records were always made with the patient in the supine position.

In contrast to the slight changes noted in but three patients with rheumatoid (infectious) arthritis, we have a 100 per cent involvement of the heart in our sixty-three patients with acute rheumatic fever, as evidenced by marked electrocardiographic observations. These electrocardiographic evidences of myocardial involvement have been sino-auricular block, nodal rhythm, interference of the sinus and auriculoventricular nodes, auricular fibrillation, auricular flutter, auriculoventricular (P-R) intervals of 0.21 second or more, heart block with dropped beats, definite R-S-T abnormalities, T wave inversions, and transient widening, notching and slurring of the Q-R-S group.

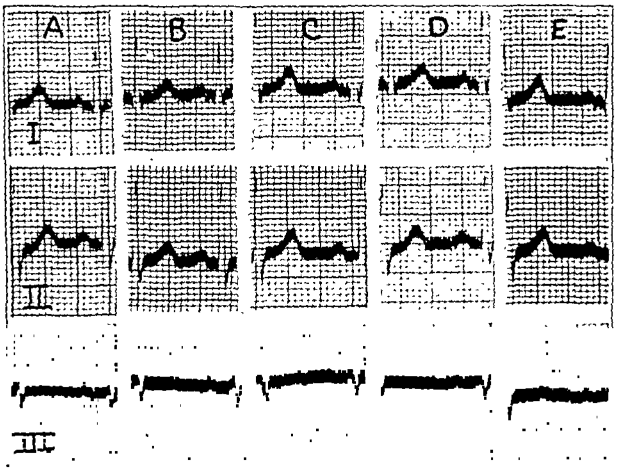

Fig. 1.—Rheumtoid (infectious) arthritis in a patient, aged 17 years. *A*, Sept. 17, 1930; *B*, September 22; *C*, September 27; *D*, October 3; *E*, October 9. (Continued in figure 2.)

Among the sixty-three rheumatic fever cases there were forty-three patients with tachycardia, the heart rate not uncommonly reaching 140 to 150 a minute. There were thirteen patients with bradycardia. Sinus arrhythmia was observed in fourteen patients and sino-auricular block in six patients. Auricular premature beats were recorded six times; ventricular, three. A simple nodal rhythm and a nodal tachycardia were each observed once. Interference of the sinus and auriculoventricular nodes was noted twice. Auricular fibrillation and auricular flutter were each seen twice.

Increased auriculoventricular conduction time (P-R interval) to 0.20 second occurred in eight cases and to more than 0.20 second in thirty-three cases, making a total of 65.6 per cent. Auriculoventricular blocks of 0.56 second were seen in the tracings. Auriculoventricular block with dropped beats were seen in three patients. The R-S-T abnormalities occurred with the greatest frequency, i. e., in fifty-three cases (84.8 per cent). T wave inversions were graphically noted in twenty-five cases (40 per cent).

COMMENT

The high incidence of myocardial involvement in acute rheumatic fever is not new. Many authors have obtained similar results. Some have found an incidence of more than 90 per cent. Cohn and Swift, and Rothschild, Sacks and Libman have predicted that every case would show myocardial involvement if daily electrocardiograms were taken.[8] This is exactly what we did. Rheumatoid (infectious) arthritis, on the other hand, has never been seriously investigated with the electrocardiogram. Rothschild, Sacks and Libman [8] did say, "In five cases of acute polyarthritis, which differed clinically from the rheumatic form, the electrical tracings exhibited none of the alterations noted in rheumatic fever." Their records were taken only once a week. These authors, however, suggested the possible clinical application of the electrocardiogram to the differential diagnosis of the two diseases.

In the many hundreds of tracings taken on the patients suffering from rheumatoid (infectious) arthritis, not once was there any change commonly considered indicative of myocardial involvement; i. e., no R-S-T abnormality, no T wave inversion, no auricular fibrillation, no auricular flutter, no case of auriculoventricular (P-R) block of more than 0.21 second, nor any block with dropped beats.

CONCLUSION

In seventeen patients with rheumatoid (infectious) arthritis on whom electrocardiograms were taken daily for an average of fifty-three days, only the slightest evidence of myocardial involvement was recorded.

In sixty-three cases of acute rheumatic fever, definite electrocardiographic evidence of myocardial involvement appeared in 100 per cent.

Rheumatoid (infectious) arthritis, no matter what it may be, is not a disease of the heart; acute rheumatic fever is preeminently a carditis.

The clinical application is this. In a case in which the differential diagnosis between rheumatoid (infectious) arthritis and acute rheumatic fever is difficult, if there are no electrocardiographic evidences of myocardial involvement, we would be prone to call it the former disease, whereas when there are electrical tracings definitely indicative of myocardial involvement we would be prone to call the disease acute rheumatic fever. The former affects the heart to the slightest degree, if at all; the latter to a maximum extent.

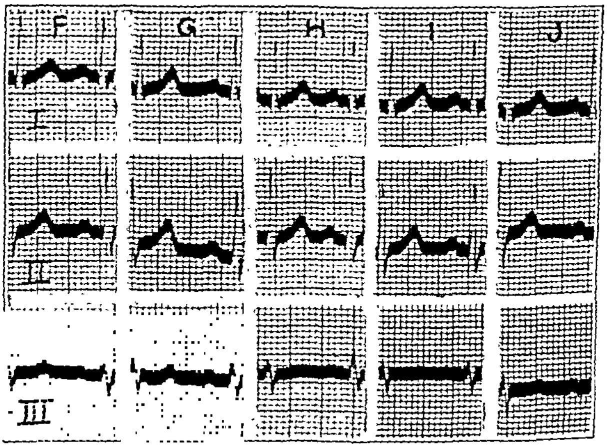

Fig. 2 (continued from figure 1).—*F*, October 15; *G*, October 20; *H*, October 25; *I*, October 31; *J*, November 5. No changes were observed in daily electrocardiograms taken over a period of forty-nine days.

DEXTROCARDIA SECONDARY TO EVENTRATION OF THE DIAPHRAGM

REPORT OF AN ASYMPTOMATIC CASE

L. MINOR BLACKFORD, M.D.
AND
WILLIAM TELFORD BOOTH, M.D.
ATLANTA, GA.

Dextrocardia with general transposition of the viscera is not particularly uncommon and offers no great difficulty in diagnosis. Isolated intrinsic dextrocardia without other grave cardiovascular maldevelopment is one of the rarest anomalies. To find a normal heart on the right side above normal liver dulness therefore suggests that the position of the heart is secondary to a defective diaphragm. Such displacement of the heart has been mentioned in many recent publications on eventration and hernia of the diaphragm. However, this point has not been emphasized in cardiologic literature, probably because, if any symptoms are present, subphrenic ones usually dominate the clinical picture.

In 1927, Christian[1] said of eventration of the diaphragm:

> The great majority of reported cases has occurred in males. It is almost invariably on the left side. . . . As the condition is congenital, both thoracic and abdominal viscera accommodate themselves to the defect, and as a result there are no symptoms. . . . The lung is not compressed, but the heart may be displaced upward or to the right. . . . The condition is shown definitely by the roentgen rays. The contour of the left leaflet is that of a smooth, sharply defined, bow-shaped shadow . . . The conditions most likely to simulate eventration are pneumothorax and congenital hernia. . . . As eventration never gives rise to any disturbance and is usually an accidental discovery, it requires no treatment.

More recently, however, Harrington[2] has said, "In some instances it is very difficult to differentiate between an eventration and a true diaphragmatic hernia." Moore and Kirklin,[3] the roentgenologists of the Mayo Clinic, have concurred in this: if the hernia is large, the heart is displaced to the right, and shading of the lung in proportion to the amount of compression is noted. In addition, they say:

> Reversed, or paradoxical, respiratory movement of the affected arch was for a time regarded as a distinguishing sign, but recent observers agree that respiratory movement may be normal, diminished, absent or reversed in either hernia or eventration. A more practical point, advanced by Morison, is that in eventration the upper level of the barium in the stomach always coincides with the esophageal opening when the patient is erect, whereas in hernia the upper level of the gastric content is likely to be above the plane of the esophageal aperture. . . . No attempt has been made at the Mayo Clinic to repair the diaphragm in cases of eventration.

Truesdale, who has emphasized cardiac symptoms in writing of diaphragmatic hernia, in a recent paper[4] on the subject said, "A dextrocardia often serves as a key to the diagnosis." He proved that the position of the diaphragm might be responsible for dextrocardia by reporting one case in which the heart was on the right before operation but reverted to its normal position after repair of the hernia.

REPORT OF CASE

History.—A school boy, aged 16, was referred for cardiologic investigation on account of dextroposition of the heart. His father had died at 29, following appendectomy. His mother was living and well, and had had only the one pregnancy. This had terminated with normal labor and delivery. The patient had been very wide awake from the beginning and had weighed 7 pounds (3.2 Kg.) at birth. When he was about 6 months old, his father had him on his lap with both hands around him when he discovered that the heart beat was strong on the right side. A physician had corroborated this observation at the time. Except for frequent attacks of tonsillitis, the child's health had been excellent until pneumonia at 8 years. The following year, he had been in bed for some weeks with diphtheria, which was said to have left him with an enlarged heart. Two years after this he had won a 4 mile cross-country race. At 12 years, a fluoroscopic examination of the chest had been made, and he had been told again that his heart was on the right and that it was "the size of a grown man's heart." Fortunately this did not worry the boy, and he continued to lead a normal athletic life. He played end on his school's football team, and indeed considered his "wind" better than that of most of his friends. He had never experienced any symptoms referable to the heart or abdominal viscera, although he was subject to frequent infections of the upper respiratory tract. His scholastic record was good.

Examination.—The patient was a muscular youth, 68¼ inches (173.4 cm.) tall, weighing 133 pounds (60.3 Kg.). There was no evidence of cyanosis or of clubbing. The eyegrounds were normal. The nasal septum was slightly deflected. The teeth were in good condition, and the tonsils had been cleanly removed. The thyroid gland was not enlarged. A rachitic rosary was present. The maximum thrust of the heart was in the fourth interspace, 6 cm. to the right of the midline, and systolic undulation was visible in the second and third interspaces above this. There were no thrills. On the right, dulness extended 3.0 cm. from the midline in the first interspace, 4.0 cm. in the second, 5.5 cm. in the third, 6.0 cm. in the fourth, and 4.5 cm. in the fifth; on the left, dulness extended 0, 2.0, 3.0, 3.5 and 2.0 cm., respectively. There were no murmurs, and the quality of the heart sounds was good. Rarely an extrasystole was detected. The right lung was normal. There was no dulness over the left lung; voice and breath sounds were normally transmitted throughout. Percussion revealed flatness over the normal area of the liver, and tympany over that of the stomach; the abdomen was soft. The genital organs, including the prostate and vesicles, the extremities and the principal reflexes, all seemed equally normal.

Urinalysis and the Kahn test gave negative results. The red cell count was 6,080,000; the leukocyte count was 6,200, and the differential count was normal. Hemoglobin was 15.2 Gm. per hundred cubic centimeters of blood.

On fluoroscopic examination, it was immediately seen that the heart was pushed to the right by the upper part of the stomach; this, distended by an air bubble, came up to the level of the fourth rib. Gas also visualized the splenic flexure of the colon to the right of the stomach, though not up so high. The upper border of these viscera appeared smooth as if under a relaxed, though intact, diaphragm. With some deep inspirations, the movement of the left half of the diaphragm seemed to us paradoxical; with others, normal though diminished. The lateral part of this leaflet always moved medially with inspiration. The patient was studied under the fluoroscope on several occasions, and with Dr. Edgar D. Shanks in consultation. Visualization of the esophagus with barium proved that it passed behind the aorta and its lower end turned sharply to the left and entered the stomach horizontally. The upper level of the barium in the stomach did not rise above the esophageal opening. The stomach extended as far down as the umbilicus and emptied normally into the duodenum on the right; peristalsis was somewhat hyperactive. After the ingestion of more barium, with the hips elevated above the shoulders, the barium entered freely the intrathoracic part of the stomach: there was no constriction at the normal level of the diaphragm

(fig. 1). The anteroposterior teleroentgenogram (fig. 2) corroborated the fluoroscopic examination; the heart was not enlarged, and markings of the lung were superimposed over the gas bubble *in the stomach*: there was no atelectasis. In an oblique view (fig. 3), however, there was a break in the contour of the diaphragm near its lateral origin.

On reexamination, it was found that the normal resonance of the left lung in front was altered to tympany at the level of the fifth rib. In the recumbent position, tympany extended to the level of the fourth rib. When the patient jumped up and down, with the stethoscope medial to the left nipple, splashing in the stomach was audible. The patient told us at a later interview that the position of the heart shifted when he turned over in bed. We found that when he lay on his right side the right border of the heart was felt and percussed 7 cm. from the midline, and the left border was percussed at the midline. When he lay on his left side, the right border extended 4.5 cm. from the midline, and the left border seemed to be 4 cm. from it.

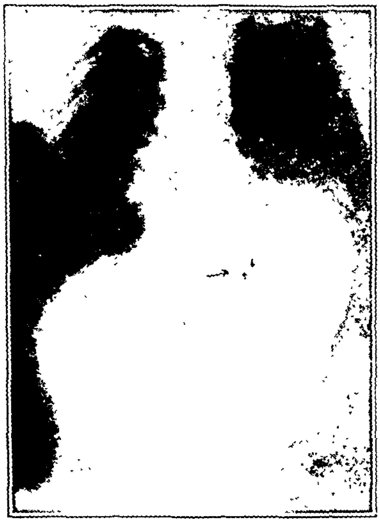

Fig. 1.—Roentgenogram taken with the stomach filled with barium and with the hips above the shoulders The cardiac portion of the esophagus is marked with an arrow. There is no constriction of the stomach at the normal level of the diaphragmatic arch.

In the electrocardiogram, by Dr. E. A. Bancker, the P, R and T waves were upright in all leads and there was no evidence of axis deviation or of abnormal cardiac mechanism.

COMMENT

At the conclusion of the history and physical examination, we were sure that this boy's heart was functionally normal. The position of the liver, stomach and left testicle established that this was not a case of general transposition. We knew that this dextroposition dated from early infancy: if not congenital, it had at least long preceded any disease affecting the intrathoracic organs. The very outline of the precordial dulness, moreover, suggested that the heart had been pushed to the right. The tympany at the base of the left lung in front should have been noted at the first examination. We believe that we should have been able to diagnose before roentgenologic examination that the position of the heart was secondary to that of the diaphragm.

It is to be emphasized that, in contrast to the "mirror picture heart" of general transposition, the heart in this case was entirely normal except for its displacement. This was proved by the roentgenogram and the electrocardiogram.

To determine whether this diaphragmatic lesion was eventration or hernia puzzled us until we read the discussion of the diaphragm by Assmann.[5] This enabled us to formulate the following theory as to our case: 1. When deep inspiration was abdominal in character, the left half of the diaphragm descended with the right but was not strong enough to descend as far as the normal half. 2. When deep inspiration was thoracic, the negative intrathoracic pressure and the elevation of the anterior attachment caused the left half of the diaphragm to ascend more than could be compensated for by its weakened musculature. 3. The muscular pull on the posterior and lateral attachments produced the medial inclination of the lateral part of the diaphragm. After formulating this theory, we examined the boy fluoroscopically for the fifth time. With forced thoracic inspiration the left half of the diaphragm did ascend; with forced abdominal inspiration it did descend.

Assmann also reported cases in which there was, in deep inspiration, a localized bulging in the upper contour of the normal diaphragm. This phenomenon was observed in persons otherwise normal, although it was noted more often in cases of tracheal or bronchial stenosis. Assmann explained it principally on the basis of inequality of the strength of various groups of muscle fibers.

The break in the contour of the diaphragm in our case is then not good evidence of hernia. If the lesion is hernia, the hernia is so large that repair would be difficult if not impossible, and strangulation is not probable; moreover, in the absence of symptoms neither the patient nor his mother would consider operation. The differential diagnosis in this case is therefore largely a matter of academic interest. However, we believe that the writings of Christian, Moore and Kirklin (including Morison), and Assmann justify us in the diagnosis of eventration of the diaphragm. If the lesion is eventration, "it requires no treatment."

We feel more confident that this boy's anomaly requires no treatment since reading the report by Livengood[6] of a case of isolated dextrocardia in a woman, aged 74, who had borne two children. From study of the roentgenologic and electrocardiographic data presented by him, we believe that this dextrocardia was also secondary to eventration of the diaphragm. However, eventration, though rare in women, is not always benign, for Dr. R. A. Bartholomew[7] is reporting a fatal case in a young woman who had been healthy until several months pregnant. In the investigation of abdominal symptoms developing at that time, it was found that the left half of the diaphragm was elevated and the heart pushed to the right. She would not consent to an abortion, so cesarean section was planned when the fetus was viable. Shortly before this time, complications precipitated labor, which resulted in complete rupture of the diaphragm and death. Eventration of the diaphragm is then a menace to the life of women in the child-bearing age. In the case of

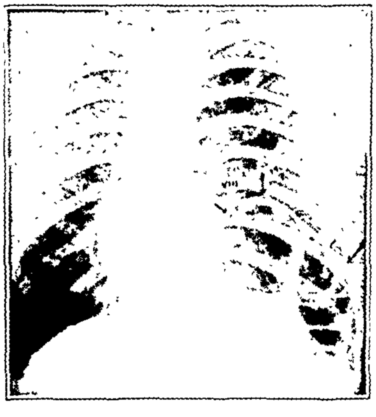

Fig. 2.—Teleroentgenogram showing the heart normal in size and contour (T. T., *27; M. R., 3.2; M. L., 6.4)* but pushed to the right by the stomach, the left ventricle resting against the cardia. The right diaphragm is normal; the left is poorly developed and ascends to the fourth rib in the midclavicular line, being pushed up by the stomach and intestine. There is no pulmonary atelectasis.

[7] Dr. Bartholomew has graciously authorized this preliminary report. The patient was also examined clinically by one of us (W. T. B.).

males, it would appear possible to us that any factor causing extraordinary increase in intra-abdominal pressure might act as labor did in Bartholomew's case. We have therefore advised this boy against the more violent forms of exercise.

SUMMARY

Congenital dextroposition of the normal heart without evidence of transposition of other viscera in most cases is probably secondary to eventration of the diaphragm. A case of this type in an athletic youth has been reported. The condition has been entirely asymptomatic up to the present, and we believe that the position of his heart will never cause the patient any trouble. It is possible, however, that subphrenic symptoms may develop or that an extraordinary increase in intra-abdominal pressure, brought on by trauma or tremendous exertion, may result in rupture of the weakened diaphragm.

Clinical Notes, Suggestions and New Instruments

TYPHOID HEPATOCHOLANGEITIS

CURE OF A "CARRIER" OF TWENTY-SIX YEARS' DURATION, WITH A FIVE YEAR "FOLLOW UP"

B. B. Vincent Lyon, M.D., Sc.D., Philadelphia

The case reported here deserves to be put on record because it indicates what may be accomplished in severe hepatocholangeitis with the persistent use of modern methods of treatment.[1]

History.—C. P. R., a man, aged 52, referred by Dr. Crawford Green of Troy, N. Y., first seen by me, Feb. 23, 1925, had had in 1898, at the age of 26, a fever diagnosed as malaria, while in army service in the Spanish War. This confined him to bed for a few days at a time, alternately defervescing and relapsing over a period of about six weeks. Between the ages of 26 and 30 he had attacks of epigastric pain associated with vomiting, jaundice and fever. These attacks occurred about every two months. Since the age of 30 he had been free from such attacks until June, 1923 (that is, for twenty-one years), but during this period he definitely damaged his cardiovascular system, liver and kidneys.

From June, 1923, he had several monthly attacks of pain in the upper right quadrant with recurring jaundice, nausea and vomiting, which led to an operation for biliary tract disease in April, 1924, in Troy, N. Y. There were found dense widespread adhesions, marked pericholecystitis, a small contracted gallbladder containing multiple stones and some pus, and some enlargement at the head of the pancreas. A cholecystectomy was done with difficulty.

Following this he convalesced slowly but with incomplete relief of the distress in the upper right quadrant. During June, 1924, he noticed soreness and tenderness under the upper abdominal scar, and during July and August a fluctuant mass could be palpated which gradually "pointed" in the lower right quadrant. He was taken to Albany, N. Y., where on Aug. 25, 1924, under local anesthesia another surgeon incised this mass. His notes are as follows: "Primary incision carried down into the sheath of right rectus muscle; on retracting fibers, there was exposed an abscessed cavity with thick fibrous walls containing a quantity of grayish thick pus, apparently under pressure, which had collected between the right rectus muscle and its posterior sheath, just below the level of the navel. The pus was evacuated, the cavity curetted, cultures were made. It was necessary to pack the wound with iodoform gauze that afternoon to control hemorrhage. B. typhosus was isolated in pure culture; the Widal agglutination reaction was positive; the Wassermann reaction was negative. B. typhosus was also recovered from the stools."

It seems necessary, therefore, to consider that the low running fever in 1898, instead of being malaria, was probably a "walking typhoid." At this point it is of moment to state that this patient was then listed by the New York State Board of Health as a typhoid carrier, twenty-six years after primary infection. A brief report of his case will be found in the *New York State Medical Journal* of Jan. 16, 1925, under Health Board Notes.

Following the patient's second hospital discharge he continued to complain of pain in the upper right quadrant, epigastric burning, distention and gas, general weakness, insomnia and constipation. Here follow the notes of his family physician, Dr. Green: "One night in October, 1924, he was seized with several general convulsions. In all, he had eight of these in intervals of about five minutes, and it took three-fourths grain (0.05 Gm.) of morphine and glycerin trinitrate to control them. Subsequently, there was considerable paresthesia of the right side with positive, but not great, paralysis of the left side of the face and inequality of pupils. All convulsions began on the right side. These symptoms, particularly the numbness, lasted for some time. Since the episode of convulsions there have been two or three attacks simulating a mild gallstone colic, with fever of a few hours' duration and jaundice for a few days." The foregoing notes accompanied the patient on his admission to a hospital in Philadelphia, Feb. 23, 1925.

Examination.—On arrival he appeared to be a very sick man; he was exhausted from his journey. He gave the impression of being highly toxic. He complained of pain in the upper right quadrant and epigastrium, abdominal distention with painful belching, and marked chilliness. His temperature ranged from 97 to 99 F. The leukocyte count was 10,100; polymorphonuclear neutrophils were 77 per cent. He was moderately jaundiced, his pulse was irregular with numerous skipped beats; the rate was 94. Peripheral arteries were considerably sclerotic. Systolic blood pressure was from 152 to 160; diastolic, 100. The left ventricle of the heart was moderately enlarged; action was overforcible; the aortic second sound was accentuated; there were numerous extrasystoles; cardiac sounds were heard through a wide area, front and back. The abdomen was distended, with moderate rigidity and spasm over the upper right rectus. The liver was not palpable; the percussion area of dulness was diminished and was sensitive to concussion. The spleen was not palpable. A persistent fistula discharging grayish pus in the lower right part of the abdomen was noted. It had required dressing twice a day since the previous August.

The right pupil was larger than the left; the left side of the mouth drooped; there were areas of anesthesia and paresthesia in the right arm and leg (adjudged as evidence of subsiding mild cerebral hemorrhage), extensive pyorrhea, and five capped teeth. Roentgen examination showed three apical abscesses. The tonsils were diseased; pus could be pressed out of the left tonsil.

Bacteriologic observations were as follows: Cultures from the gums and tonsils yielded Staphylococcus aureus, nonhemolytic streptococcus; from the bile drainage, B. typhosus, Staphylococcus aureus; from the abdominal sinus, B. typhosus, Staphylococcus albus; from the feces, B. typhosus, B. coli;

---

[1] A more complete review of the subject appeared in the Journal of the Medical Society of New Jersey 28:799 (Nov.) 1931.

from the urine, B. coli and Staphylococcus albus, with no B. typhosus.

Urinalysis revealed no albumin, dextrose or ketones, and no fixation of specific gravity; there were occasional hyaline casts. Renal function was reduced to 12.5 per cent the first hour and 7.5 per cent the second hour on intramuscular injection of phenolsulphonphthalein. The twenty-four hour urine output was 500 cc.

The diagnosis was typhoid hepatocholangeitis; myocarditis; arteriosclerosis; toxic vs. interstitial nephritis; subsiding hemiplegia, and persistent abdominal sinus.

Treatment and Course.—General supportive treatment of the heart and kidneys was instituted; the protein diet was reduced; biliary drainage was given, and subsequently a combined polyvalent vaccine: B. typhosus from bile, sinus and feces; Staphylococcus aureus from the gums; nonhemolytic streptococcus from dental apical abscesses and tonsils.

Fifteen three-hour biliary drainages were given between February 25 and March 31, yielding 4,205 cc. of bile mixture weighing 3,936 Gm. (8⅓ pounds).

Four periods of "continuous plan" drainage between April 1 and 12 were given, yielding 10,235 cc. weighing 11,230 Gm. (23⅞ pounds). The pain was controlled after the first two drainages. Jaundice cleared, March 7, after five drainages. On March 14 the question of using mercurochrome-220 soluble intravenously as a magna sterilisans procedure was considered and declined because of depreciated kidney function. Had it been used, the interpretation of the successful results would have been complicated.

These liver drainages, yielding 3½ gallons (14 liters) in about six weeks, thinned out the bile from a very viscid, turbid, heavy sediment, multiple floccule type, microscopically rich in pus cells, inflammatory detritus and many colonies of bacteria, to a much clearer bile of thinner consistency and constantly diminishing floccules. Quantitative colony counts for B. typhosus were steadily reduced, although still positive in bile and feces, but negative in sinus cultures on the patient's discharge from the hospital, April 24.

The immediate response to treatment was quite spectacular. This very sick man stood the drainages very well; he was first out of bed on the fifteenth day; he lunched at a hotel on the twenty-fifth day. There was rapid subsidence of the toxic picture; the cardiorenal function improved with corresponding improvement in the blood, on chemical examination. Nonprotein nitrogen dropped from 50 mg. to 25.2; urea nitrogen from 20 mg. to 11.1; uric acid from 4.16 mg. to 2.91; dextrose and creatinine practically unchanged, from 149 mg. to 148, and from 1.88 mg. to 1.87, respectively.

From then on the progress of this case was tedious but progressively good. Under the supervision of his family physician and a technical nurse he continued biliary drainages throughout the summer of 1925 at intervals of from four to seven or ten days and an overnight drainage occasionally.

He returned to Philadelphia for a first recheck, October 6 to 14. Cultures from bile, feces and sinus were made each day for three days and twice more on alternate days, and B. typhosus was not found. He was advised to have the abdominal sinus surgically repaired, but he persistently declined. On his return to Troy additional cultures were made by the New York State Board of Health and were negative for typhoid, and the patient was released as a "carrier."

Over the next two years recultures were made a number of times, both in Troy and in Philadelphia, and were negative for B. typhosus. He had gained from 153 to 177 pounds.

Throughout 1926 and 1927 he took a short morning or an overnight drainage about once a month. The abdominal sinus, although yielding no growth to cultures, would not close. He was again advised to have it closed.

On Jan. 17, 1927, he writes: "On January 4, Dr. ——— probed the sinus; a few threads were exposed, and caught in forceps; the doctor gradually pulled out a roll of gauze about 4 inches long and seven-eighths inch in diameter. The wound drained slightly for about ten days and is now all healed. I thought you would like to have this for your records."

Final Results.—The patient has been followed up by letter twice a year. He last reports, Sept. 26, 1931, as follows: "Your letter of the 25th was received this morning. I am glad to report that my digestive apparatus is in good order. I have not had an ache or a pain since I first left your hospital. I go shooting nearly every day in the fall and winter and trout fishing equally as much in the spring and summer. The examining surgeons have twice refused me an increase of government pension, saying that I am in very good shape considering my 58 years of age. For the past two years I have not been on any diet nor taken extra care of myself, but it does not seem to make any difference. It is over three years since I have had a biliary drainage."

2031 Locust Street.

Council on Physical Therapy

The Council on Physical Therapy of the American Medical Association has authorized pulication of the following report.

H. A. Carter, Secretary.

DeVILBISS ATOMIZERS, POWDER BLOWERS AND VAPORIZERS ACCEPTABLE

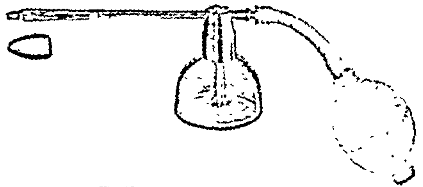
The DeVilbiss Company, Toledo, Ohio, manufactures atomizers, powder blowers and vaporizers (nebulizers) for medicinal use. The twenty-eight products herein mentioned appear to be of good construction and the claims made for them meet the requirements of the Council.

DeVilbiss atomizers are recommended by the firm for applying a spray of medicinal agents to tissues in liquid form. The specifications of fifteen atomizers follow:

DeVilbiss Atomizer No. 12.—Spraying parts made of hard metal, nickel plated and polished. One piece, adjustable gold plated tip. One drachm bottle. Detachable nasal guard. Glass outlet tube. Taper connection between bulb and atomizer, permitting instant detachment. Vacuum plan construction.

DeVilbiss Atomizer No. 14.—Spraying parts made of hard metal, nickel plated and polished. Detachable nasal guard. Glass outlet tube. One drachm bottle. Especially constructed for spraying ephedrine and similar oil solutions. Compression type construction.

DeVilbiss Atomizer No. 15.—Spraying parts made of hard metal, nickel plated and polished. One piece, adjustable gold plated tip. Detachable nasal guard. Glass outlet tube. Taper connection between bulb and atomizer, permitting instant detachment. Vacuum plan construction.



DeVilbiss atomizer No. 15

DeVilbiss Atomizer No. 16.—Spraying parts made of hard metal, nickel plated and polished. One piece, adjustable gold plated tip. Detachable nasal guard. Glass outlet tube. Extra amber bottle with stopper. Taper connection between bulb and atomizer, permitting instant detachment. Vacuum plan construction.

DeVilbiss Atomizer No. 18.—Spraying parts made of hard metal, nickel plated and polished. One piece, adjustable gold plated tip. Closure valve on head directly over the bottle makes a nonspillable outfit for travelers' use. Detachable nasal guard. Glass outlet tube. Taper connection between bulb and atomizer, permitting instant detachment. Vacuum plan construction.

DeVilbiss Atomizer No. 28.—Spraying parts made of hard metal, nickel plated and polished. Inner tube easily removed for cleaning. Detachable nasal guard. Glass outlet tube. Taper connection between bulb and atomizer permitting instant detachment. Vacuum plan construction.

DeVilbiss Atomizer No. 30.—Spraying parts made of hard metal, nickel plated and polished. Glass outlet tube. Constructed on vacuum principle and anatomically correct for nasal use.

DeVilbiss Atomizer No. 150.—Spraying parts made of hard metal, chromium plated and polished. Inner tube easily removed for cleaning. Glass outlet tube. Vacuum plan construction.

DeVilbiss Atomizer No. 152.—Spraying parts made of hard metal, chromium plated and polished. One piece, adjustable gold plated tip. Glass outlet tube. Vacuum plan construction.

DeVilbiss Atomizer No. 154.—Spraying parts made of hard metal, chromium plated and polished. Spray tube easily detached for sterilizing. One piece, adjustable gold plated tip. Glass outlet tube. Vacuum plan construction.

DeVilbiss Atomizer No. 155.—Exterior of atomizer chromium plated and polished. Inside of bowl gold plated. One piece, adjustable gold plated tip. Small container for individual doses. Detachable nasal guard. Vacuum plan construction.

DeVilbiss Atomizer No. 156.—Spraying parts made of hard metal, chromium plated and polished. Interchangeable spray tips; postnasal tube, four-way tip and one-way tip. Glass outlet tube. Constructed on compression principle.

DeVilbiss Atomizer No. 158.—Spraying parts made of hard metal, chromium plated and polished. Glass outlet tube. Constructed on compression principle. Especially for ephedrine and similar oil solutions.

DeVilbiss Atomizer No. 159.—Spraying parts made of hard metal, chromium plated and polished. One piece, adjustable gold plated tip. Cutoff button on top of spray head for stopping spray instantaneously and substituting a flow of air. Glass outlet tube. Vacuum plan construction.

DeVilbiss Atomizer No. 251.—Spraying parts made of hard rubber. Detachable nasal guard. Hard rubber outlet tube. Inner tube easily removed for cleaning. Taper connection between bulb and atomizer, permitting instant detachment. Vacuum construction.

DeVilbiss vaporizers (nebulizers), the firm claims, are used to create a vapor for inhalation of medicinal agents in an oil base.

DeVilbiss Vaporizer No. 41.—Constructed to produce a vapor only from oil solutions. Spraying parts made of hard metal, nickel plated and polished. Detachable nasal guard. Glass outlet tube. Taper connection between bulb and vaporizer, permitting instant detachment.

DeVilbiss Electric Vaporizer No. 47.—Constructed for applying warmed medication in the form either of solutions or of vapor ointments. Consists of a black case with electric plug and top made of hard metal, nickel plated and polished. Detachable nasal guard. Taper connection between bulb and vaporizer, permitting instant detachment.

DeVilbiss Vaporizer No. 48.—Constructed to produce a large volume of extra dry vapor from oil solutions. Spraying parts made of hard metal, chromium plated and polished. Detachable nasal guard. Glass outlet tube. Taper connection between bulb and vaporizer, permitting instant detachment.

DeVilbiss Vaporizer No. 49.—Constructed to produce a vapor only from oil solutions. Spraying parts made of hard metal, nickel plated and polished. Detachable nasal guard. Glass outlet tube. Metal table inside bottle for regulating density of vapor. Taper connection between bulb and vaporizer, permitting instant detachment.

DeVilbiss Vaporizer No. 180.—Constructed to produce a vapor only from oil solutions. Spraying parts made of hard metal, chromium plated and polished. Detachable nasal guard. Glass outlet tube. Metal table inside bottle for regulating density of vapor.

DeVilbiss Vaporizer No. 181.—Constructed to produce a large volume of extra dry vapor from oil solutions. Spraying parts made of hard metal, chromium plated and polished. Detachable nasal guard. Glass outlet tube.

DeVilbiss powder blowers, it is claimed, are used to apply a medicament in powdered form.

DeVilbiss Powder Blower No. 36.—Spraying parts made of hard metal, nickel plated and polished. Adjustable tip. Glass outlet tube. Taper connection between bulb and atomizer, permitting instant detachment. Compression plan construction.

DeVilbiss Powder Blower No. 175.—Spraying parts made of hard metal, chromium plated and polished. Single metal outlet tube stops clogging. Compression plan construction.

The following specialized instruments have been investigated:

DeVilbiss Electric Steam Vaporizer No. 42.—Constructed to produce a warm medicated vapor. Cover spout, medicine chamber and heating element housing made of bakelite. Glass jar. Electric cord with plugs. Carbon electrodes provide heating device. Especially constructed to insure perfect medication of vapor and eliminate any possibility of throwing drops of the solution. Current automatically cuts off when water is evaporated.

DeVilbiss Wax Sprayer No. 110.—Constructed for heating and spraying waxlike substances on burns. Container and top made of hard metal, nickel plated and polished. Water jacket and preparation container in one piece. Taper connection between bulb and sprayer, permitting instant detachment.

DeVilbiss Wax Sprayer No. 113.—Single container outfit for spraying waxlike substances on burns. Container and top made of hard metal, nickel plated and polished. Taper connection between bulb and sprayer, permitting instant detachment.

DeVilbiss Syringe No. 157.—Constructed for producing a stream and designed primarily for washing the middle ear. Spraying parts made of hard metal, chromium plated and polished. Glass outlet tube. Spray tip is detachable, making it possible to use other tips that are available.

DeVilbiss Irrigator No. 190.—Constructed to produce a fine stream in treating eyes. Spraying parts made of hard metal, chromium plated and polished. Graduated scale on bottle. Bulb attached directly on to bottle, making a compact outfit.

The DeVilbiss Company makes no therapeutic claims for the instruments alone. It is claimed, however, that the aforementioned instruments will apply medicaments in liquid or powder form in a proper manner and in accordance with the wishes of the physician prescribing their use.

The Council on Physical Therapy accepts the aforementioned atomizers, powder blowers and vaporizers (nebulizers) for inclusion in its list of accepted devices for physical therapy.

Council on Pharmacy and Chemistry

NEW AND NONOFFICIAL REMEDIES

The following additional articles have been accepted as conforming to the rules of the Council on Pharmacy and Chemistry of the American Medical Association for admission to New and Nonofficial Remedies. A copy of the rules on which the Council bases its action will be sent on application.

W. A. Puckner, Secretary.

DECHOLIN.—Dehydrocholic Acid.—An oxidation product of cholic acid derived from natural bile acids.

Actions and Uses.—(See Bile Salts and Bile Salt Compounds, New and Nonofficial Remedies, 1931, p. 92). Decholin is proposed for use in functional insufficiency of the liver; to outline the bile ducts at operation and in relieving the possible occurrence of some of the postoperative symptoms; in cholecystography, to accelerate the appearance of the gallbladder shadow and to hasten removal of residual tetraiodophenolphthalein from the biliary apparatus; in cardiac decompensation with hepatic congestions, cirrhosis of the liver and similar disturbances of hepatic function with ascites.

Dosage.—From 0.25 to 0.5 Gm. (4 to 8 grains) two to three times daily after meals for a period of four to six weeks.

Manufactured by J. D. Riedel-E. de Haen, A. G. Berlin, Germany (Riedel-de Haen, Inc., New York, distributor). No U. S. patent. U. S. trademark 266,217.

Decholin Tablets, 3¾ grains.

Decholin occurs as a fine, colorless, crystalline powder with a bitter taste; sparingly soluble in alcohol and glacial acetic acid. It melts at 233-235 C.

Boil about 1 Gm. of decholin with 100 cc. of water for two minutes; no odor develops; cool and filter: Separate portions of 10 cc. each of the filtrate yield no opalescence with 1 cc. of diluted nitric acid and 1 cc. of silver nitrate solution (*chloride*); no turbidity with 1 cc. of diluted nitric acid and 1 cc. of barium nitrate solution (*sulphate*); no turbidity with 1 cc. of diluted sulphuric acid (*soluble barium compounds*); no coloration or precipitation on saturation with hydrogen sulphide (*salts of heavy metals*).

Dry about 1 Gm. of decholin, accurately weighed, at 100 C.: The loss in weight does not exceed 1.5 per cent. Incinerate about 1 Gm. of decholin, accurately weighed: The residue does not exceed 0.1 per cent. Dissolve about 0.5 Gm., accurately weighed, in 40 cc. of previously neutralized alcohol, dilute with about one-half the volume of water and titrate with tenth-normal sodium hydroxide solution using phenolphthalein as an indicator: The amount of tenth-normal sodium hydroxide solution consumed corresponds to not less than 98.5 per cent nor more than 101.5 per cent.

DECHOLIN SODIUM.—Sodium Dehydrocholate.—The sodium salt of dehydrocholic acid.

Actions and Uses.—(See Bile Salts and Bile Salt Compounds, New and Nonofficial Remedies, 1931, p. 92). The actions and uses of decholin-sodium are the same as those of decholin.

Dosage.—Decholin-sodium is administered intravenously. One injection is given on each of three successive days. According to the urgency of the case, the first dose consists of from 5 to 10 cc. of the 20 per cent solution; the second and third, of 10 cc. The 5 per cent solution may be used at the beginning or the end of the treatment or when a less intensive effect is desired.

Manufactured by J. D. Riedel-E. de Haen, A. G. Berlin, Germany. (Riedel-de Haen, Inc., New York, distributor). No U. S. patent. U. S. trademark 266,217.

Ampoules Solution Decholin-Sodium, 5 per cent, 10 cc.
Ampoules Solution Decholin-Sodium, 20 per cent, 10 cc.

Decholin-sodium occurs as a fine, colorless, crystalline powder with a very bitter taste, soluble in water and alcohol. An aqueous solution is alkaline to litmus.

Dissolve about 1 Gm. of decholin-sodium in 200 cc. of water; add an excess of hydrochloric acid; collect the resultant dehydrocholic acid on a filter, wash, and recrystallize from 80 per cent acetic acid; it melts at 233-238 C.

Dissolve about 0.5 Gm. of decholin-sodium in 100 cc. of water, acidify with hydrochloric acid and filter: Separate portions of 10 cc. each of the filtrate yield no turbidity with 1 cc. of barium chloride solution (*sulphate*); no coloration or precipitation on saturation with hydrogen sulphide (*salts of heavy metals*).

Dry about 1 Gm. of decholin-sodium, accurately weighed, to constant weight at 100 C.: The loss in weight does not exceed 7 per cent. Weigh accurately about 1 Gm. in a tared platinum crucible, add 2 cc. of sulphuric acid, gently heat while fumes of sulphur trioxide are evolved, repeat, using two portions of 1 cc. of sulphuric acid, respectively, ignite, cool and weigh as sodium sulphate: The percentage of sodium corresponds to not less than 5.3 per cent, nor more than 5.6 per cent, when calculated to the dried substance.

TUBERCULIN DENYS (See New and Nonofficial Remedies, 1931, p. 369).

The Cutter Laboratory, Berkeley, Calif.

Tuberculin B. F. (Bovine).—A tuberculin Denys prepared with bovine cultures of Bacterium tuberculosis; preserved with cresol; for use in dilutions only. Marketed in 1 cc. vials; also in serial dilutions.

Committee on Foods

The following products have been accepted by the Committee on Foods of the American Medical Association following any necessary corrections of the labels and advertising to conform to the Rules and Regulations. These products are approved for advertising in the publications of the American Medical Association, and for general promulgation to the public. They will be included in the Book of Accepted Foods to be published by the American Medical Association.

Raymond Hertwig, Secretary.

CALIFORNIA FRUIT GROWERS EXCHANGE ADVERTISING FOR SUNKIST ORANGES, LEMONS AND GRAPEFRUIT

Sponsors.—California Fruit Growers Exchange, Los Angeles. This exchange is a cooperative marketing organization owned and operated by 13,000 citrus fruit growers. The exchange sells the fruit for the growers to the fruit trade.

Description.—"Sunkist" brand fresh mature oranges, grapefruit and lemons which pass the exchange standards for maturity, appearance and eating quality. Frost damaged fruit is excluded.

Harvesting, Shipment and Distribution.—

Oranges: Approximately 60 per cent of all oranges and 85 per cent of all lemons consumed in the United States and Canada are grown in California. The navel and Valencia are the two chief varieties of oranges. The navel orange ripens in the fall and winter and is packed and shipped from November to May. This orange has a "navel" formation at the end opposite the stem and is seedless. The Valencia orange ripens from April until November. This orange is almost seedless. The harvesting of oranges in California therefore proceeds throughout the year and fresh fruit is always available on the market. The other varieties of oranges, Mediterranean sweets, bloods, St. Michaels, seedlings and tangerines are relatively unimportant.

More than 210,000 acres of California are planted with orange trees which are budded seedlings. The bud is from pedigree trees. The trees must be carefully nurtured and cared for. "Sunkist" oranges are harvested at the time of maturity equal to or higher than that called for by state or federal requirements. Damaged fruit is not permissible under the "Sunkist" brand. A small percentage of the fruit is treated with ethylene gas at the beginning of the shipping period of some varieties to hasten exterior color development. Only fruit passing fixed requirements of maturity, appearance and all around satisfaction and dependability are packed as "Sunkist" oranges.

The oranges are clipped from the trees and carefully handled to prevent injuries in which decay spores may lodge and later attack the fruit. The fruit is carefully laid in boxes that have been dipped in antiseptic solution. All pickers wear gloves. The fruit is conveyed to packing houses, where it is allowed to stand for several days to permit evaporation of some moisture from the rind to make the skin less subject to injury; it is thoroughly washed in warm water to remove dust, rinsed with cold water and dried by air blast.

The oranges on endless canvas belts are graded into classes. The different grades are separated by sizing machines into groups of different sizes. The best oranges of the different sizes are classed as "Sunkist," which word is indelibly stamped on the skin of each orange. Usually from one half to two thirds of the fruit qualify for the "Sunkist" grade. The oranges are packed in the familiar orange crates and sold by size, 80, 100, 126, 150, 176, 200, 216, 252, 288 and 324 respectively to the box. The freight cars of oranges are refrigerated in summer and heated in winter.

Lemons: The lemon tree produces throughout the year. Some trees yield as high as 3,000 fruit. The buds, flowers and fruit are on the tree at the same time. California thus markets fresh lemons throughout the year. The two prominent varieties are the Lisbon and the Eureka. There are more than 45,000 acres of lemon planting in California.

The culture of the lemon tree is similar to that for the orange tree.

Lemons are picked according to size rather than by color, all grades of lemons being picked green. Picking crews pass through the groves each six weeks, carrying rings 2¼ to 2⅜ inches in diameter, which are slipped over the fruit. Lemons passing through the ring are left on the tree. Fruit not passing through the rings is picked by clipping and handled with great care, as described for oranges.

The green fruit is separated from the yellow at the packing house and placed in storage rooms to cure at 18 C. and a humidity of 85. The skin in curing gradually assumes a waxy yellow color. When ready for shipment the lemons are removed from storage, carefully graded for size, and packed 240, 270, 300, 360, 420, 442 and 490 to the box.

Grapefruit: There are more than 14,000 acres planted with grapefruit in California. The Marsh seedless is the principal fruit grown. Harvesting extends from November to the following August in the various districts. The grapefruit is handled and packed as described for the orange. In order to develop the flavor, the grapefruit is sometimes stored and cured before shipment as described for the lemon.

Analysis (submitted by the exchange).—

Oranges (Citrus sinensis)
Average proximate analysis, edible portion

	per cent
Moisture	85.7
Ash	0.6
Fat (ether extract)	0.0
Protein (N × 6.25)	0.6

Carbohydrates other than crude fiber (by difference)	10.9
Acids as citric	2.2

Calories.—Approximately 0.6 per gram; 17 per ounce.

Vitamins.—Citrus fruits are a fair source of vitamin A, a good source of B and an excellent source of vitamin C.

Claims of Exchange.—Sunkist citrus fruits have a distinctive flavor and rich juice, contain minerals and carbohydrates which metabolically are antagonistic to acidosis of both the acid-ash and acetone type, and stimulate appetite. The vitamin C content is quite constant and according to some experimental evidence tends to arrest such tooth decay, gum troubles and pyorrhea as may be due to the deficiency of that vitamin. Fresh Sunkist fruits are available the year round.

SPAULDING'S SUNSHINE VITAMIN D BREAD

Manufacturers.—R. Z. Spaulding Co. (the holding company), Binghamton, N. Y.

R. Z. Spaulding Co., Elmira, N. Y.
Huddleston-Walton Co., Oneonta, N. Y.
Henry German Baking Co., Scranton, Pa.
Henry German Baking Co., Wilkes-Barre, Pa.
R. Z. Spaulding Co., Middletown, N. Y.
Hazelton Baking Co., Hazelton, Pa.
Merchants Baking Co., Shamokin, Pa.

Description.—A white bread prepared by the sponge dough method containing an added special nutrient vitamin D equivalent to the vitamin D of three teaspoonfuls of standard cod liver oil for each 24 ounces of baked bread (140 vitamin D units defined by the Council on Pharmacy and Chemistry, New and Nonofficial Remedies, 1931, page 414) and manufactured under license granted by the General Baking Company of New York.

Manufacture.—The sponge dough ingredients, patent flours of spring and winter wheats, water, yeast and a yeast food containing calcium sulphate, ammonium chloride, sodium chloride and potassium bromate, and malt syrup are mixed in a high speed mixer. The sponge dough is fermented for four hours, after which are added flour, water, sweetened condensed skim milk, salt, lard, sucrose, malt syrup and corn oil containing irradiated ergosterol to make the completed dough, which is cut into pieces of desired weight. The pieces are fermented for a short time, molded into loaf form, panned, further fermented, baked for from forty to forty-five minutes, cooled, and wrapped in wax-paper.

The factory, equipment and storage rooms for the materials used are kept in strictly sanitary condition.

Analysis (submitted by manufacturer).—

	per cent
Moisture (entire loaf)	34.5
Ash	1.6
Fat	1.2
Protein (N × 6.25)	9.4
Crude fiber	0.4
Carbohydrates other than crude fiber (by difference)	52.9

Calories.—2.6 per gram; 74 per ounce.

Vitamins.—The vitamin D (irradiated ergosterol) is incorporated in this bread under license granted by the General Baking Company of New York. A vegetable oil solution of vitamin D standardized by biologic tests is added to the bread dough in quantities guaranteed by the Pediatric Research Foundation of Toronto to be equivalent to 140 D units, or the vitamin D of three teaspoonfuls of standard cod liver oil for each 24 ounces of bread. The baked bread is continuously assayed by that foundation for verification. The D units are those defined by the Council on Pharmacy and Chemistry of the American Medical Association (New and Nonofficial Remedies, 1931, page 414).

Claims of Manufacturer.—This bread provides substantial amounts of vitamin D needed in normal nutrition.

HYGEIA PURE STRAINED SPINACH

Contains Vitamin D

Added Irradiated Ergosterol (mildly seasoned with salt)

Manufacturer.—Snider Packing Corporation, Rochester, N. Y.

Distributor.—Hygeia Nursing Bottle Company, Buffalo, N. Y.

Description.—Strained spinach retaining in large measure the mineral and vitamin content of the raw spinach used; with added vitamin D (irradiated ergosterol), 60 D units per fluidounce; packed in jars. The D units are those defined by the Council on Pharmacy and Chemistry of the American Medical Association (New and Nonofficial Remedies, 1931, p. 414). One fluidounce is equivalent in vitamin D to the D content of one teaspoonful of cod liver oil. Mildly seasoned with salt.

Manufacture.—Local farmers are contracted with for growing and delivering the spinach, which is purchased under U. S. government inspection grades. The sorted spinach is passed through a dry "riddler," which removes loose and dry foreign material, is washed in an eccentric type tank washer, is wilted by application of water at 70 C. followed by a "shot" of steam and filled into No. 10 cans, and salt solution is added. The filled cans are sealed and processed for fifteen minutes at 122 C.

The canned spinach is puréed by essentially the same procedure as described for the Strained Peas (THE JOURNAL, Feb. 13, 1932, p. 555). The processing of the final canned product is that described for the Strained Peas.

Irradiated ergosterol is incorporated in the spinach, as described for the Strained Peas.

CLAUSSEN'S BREAD

Manufacturer.—H. H. Claussen's Sons, Augusta, Ga.

Description.—A white bread made by the sponge dough method.

Manufacture.—The sponge dough ingredients, short patent flours of southwest and northwest wheats, water, yeast and a yeast food containing calcium sulphate, ammonium chloride, sodium chloride and potassium bromate, are mixed in a high speed mixer. The sponge dough is fermented for from four to five hours, after which are added flour, water, salt, sucrose, lard and sweetened condensed whole milk to make the completed dough, which is cut into pieces of desired weight. The pieces are fermented for a short time, molded into loaf form, panned, further fermented, baked for from thirty to thirty-five minutes, cooled, and wrapped in wax-paper.

The factory, equipment and storage rooms are kept in strictly sanitary condition.

Analysis (submitted by manufacturer).—

	per cent
Moisture (entire loaf)	37.6
Ash	1.6
Protein (N × 6.25)	8.9
Fat	3.0
Crude fiber	0.3
Carbohydrates other than crude fiber (by difference)	48.6

Calories.—2.6 per gram; 74 per ounce.

Claims of Manufacturer.—A bread of good quality.

CLAUSSEN'S OLD-TIMEY BREAD

Manufacturer.—H. H. Claussen's Sons, Augusta, Ga.

Description.—A white bread made by the straight dough method.

Manufacture.—The dough ingredients, patent flour, water, cake flour, yeast, salt, sucrose, skim milk and lard, are mixed in a high speed mixer. The dough is fermented for two hours, molded into loaf form, panned, baked for from forty-five to sixty minutes, cooled, and wrapped in wax-paper. The factory, equipment and storage rooms for the materials used are kept in strictly sanitary condition.

Analysis (submitted by manufacturer).—

	per cent
Moisture (entire loaf)	32.8
Ash	1.1
Protein (N × 6.25)	9.2
Fat	3.6
Crude fiber	0.3
Carbohydrates other than crude fiber (by difference)	53.0

Calories.—2.8 per gram; 80 per ounce.

Claims of Manufacturers.—A bread of good quality.

REPORTS OF THE COMMITTEE

THE COMMITTEE HAS AUTHORIZED PUBLICATION OF THE FOLLOWING REPORT.
RAYMOND HERTWIG, Secretary.

"SWEET WHEAT BREAD" NOT ACCEPTABLE

The Vermont Baking Company, White River Junction, Vt., submitted to the Committee on Foods a white bread called "Sweet Wheat Bread." This bread is prepared by the sponge dough method from short patent flours of northwest and southwest wheats, water, malt syrup, a yeast food containing calcium sulphate, ammonium chloride, sodium chloride and potassium bromate, dry skim milk, salt, dextrose, lard and a partially hydrolyzed starch.

Analysis (submitted by manufacturer).—

	per cent
Moisture (entire loaf)	37.5
Ash	1.6
Fat (ether extract)	2.7
Protein (N × 6.25)	9.2
Crude fiber	0.2
Carbohydrates other than crude fiber (by difference)	48.8

Discussion of Name.—The name implies that this is a "sweetened bread" containing materially more sugar and sweeter of taste than the usual white breads, which is not true to fact; it is inapplicable to a bread of the stated composition and is misleading. The manufacturer is unwilling to accept the Committee's recommendation for correcting the trade name; therefore this bread cannot be listed among the Committee's accepted foods.

SATURDAY, MARCH 12, 1932

NORMAN BAKER VERSUS THE AMERICAN MEDICAL ASSOCIATION

The jury in the case of Norman Baker versus the American Medical Association, trial of which was completed on Thursday, March 3, after some four weeks of court procedure, returned a verdict for the Association. The editorials to which Baker objected were published in The Journal, April 12 and 19, 1930, and in *Hygeia*, May, 1930. During the trial, attorneys for the Association, headed by Mr. C. M. Burke of Messrs. Loesch, Schofield, Loesch and Burke, introduced evidence, justifying the statements that had been made. With Mr. Burke were associated Mr. C. L. Harrell of the same firm and Mr. Charles M. Dutcher, Iowa City. In addition to depositions introduced in great number, expert testimony was given for the Association by Drs. Francis Carter Wood, Joseph C. Bloodgood, Burton T. Simpson, Albert C. Broders and Max Cutler. Many other physicians aided the Association in this case. As was anticipated, the case of Norman Baker included primarily depositions and testimony offered by patients who considered themselves cured of what they believed to be cancer, and statements by various other individuals who claimed special competence in the cancer field, most of these "experts" being the subjects of previous reports by the Bureau of Investigation. The detailed account of the trial will be made available by the Bureau of Investigation in The Journal next week.

In publishing its reports on charlatanism and quackery, the American Medical Association fulfils a duty to the medical profession and to the public. Through the radio station KTNT, no longer on the air, Baker reached vast numbers of people. Newspapers, educational authorities, officials of county and state medical societies and numerous physicians, particularly in Iowa, Illinois, Wisconsin and Minnesota, asked The Journal to aid in combating the type of information that Baker was disseminating. Evidence offered by Baker himself indicated that his income from his medical activities, beginning at $1,300 per month, rose to approximately $75,000 per month in the heydey of his efforts and was reduced to some $7,000 in January, 1932, following the publication of articles concerning these activities by The Journal and by *Hygeia.*

During the progress of the trial, many organs of public expression intimated a realization of the significance of this work of the American Medical Association. The editorial statement of the Columbus (Ohio) *Evening Dispatch* is typical:

> In the suit of Norman Baker, of Muscatine, Iowa, against the American Medical association, Mr. Baker asks for $500,000, on the ground that the association has been guilty of libel in its exposure of his cancer curing claims and methods.
>
> The brief accounts of the trial carried in the press dispatches do not indicate that Mr. Baker is likely to get his $500,000. They do indicate that what he objects to as a libel was in reality a public service of great value.
>
> A former partner of Baker in his business was called by him as an expert witness, last Friday. Federal Judge Norbye, however, insisted first on knowing what were his qualifications for testifying as an expert in the field of cancer cure, and what he found out, by a few well directed questions, was that the man's education had not passed beyond the eighth grade in the public schools and that his work up to the time when he began treating cancer patients had been that of a surveyor's assistant and a coal miner.
>
> Other "expert witnesses" called by Baker were of the same type, for the most part, and were of course not permitted to testify as experts. There are few worse evils in the field of the public health than "cancer doctors" of the Baker type.

The evidence brought forth arouses pity for the situation that can permit the poor, the sick and the ignorant to be exploited. Justification by the courts of the condemnation given by The Journal to such exploitation repays but in small measure those who have suffered. The only answer that charlatanism can make to the publication of facts is a suit for libel. In its efforts to protect the public, The Journal and the American Medical Association have been not rarely compelled to respond to such suits. Fortunately the Association is able to answer adequately. The appreciation of the medical profession and of the public is tendered to all those who have cooperated to bring to a successful issue the case of Norman Baker versus the American Medical Association.

THE REFORM OF FOOTBALL

Recently, at the end of a football season in which many lamentable fatalities and injuries were brought into national prominence, The Journal[1] protested against such an unnecessary menace to health and life. As football has had a greater incidence of fatalities and permanent injuries than that shown by any other sport, it was pointed out that the all-powerful rules committee ought to consider carefully what it could do to lessen the hazards of the game. The committee has recently issued[2] an official statement of the changes made in the code for the 1932 season and the reasons for them. On reading the details for the first time one may well recall the familiar aphorism that "confession is good for the soul."

---

1. Football Fatalities, editorial, J. A. M. A. **97:** 1802 (Dec. 12) 1931.
2. The full text of the statements, by E. H. Hall and W. S. Langford, appeared in the daily papers of February 16.

The survey on which the reform program was based included a study of 49 deaths and 1,346 injuries in colleges, high schools, athletic clubs and "sand-lot groups" last season. The direct causes of some of the fatal accidents are listed as follows: improper support from interference, 1; head-on tackle, 4; unnecessary roughness, 2; player relaxed before ball was dead, 2; tackling in practice, 2; poor physical condition of the player, 6; piling on, 2. The parts of the body injured include almost every region of the exterior, in addition to ill defined "internal injuries." These vague generalizations suffice to indicate the implied culpability of sport leaders who acquiesced in the continuance of such unwholesome conditions in the athletic field until change was made imperative by the growing volume of reproach directed against those who tolerated them.

It may be ungracious to refer flippantly to some of the proposed changes. They illustrate, however, the extent to which health hazards had been developed and tolerated. With respect to the change in equipment, we learn that hereafter hard and unyielding substances used in the construction of protective devices must be covered on the outside with padding at least three eighths of an inch thick. This sounds like one of the international agreements with respect to armor plate or the construction of army tanks or other implements of war. Frankly, it means that the protective devices have become so dangerous that the antagonist is entitled to some amelioration of the dangers to which he is exposed thereby. Again, players on the defense are forbidden to strike an opponent on the head, neck or face but may use the palm of the hands to ward off or push such an opponent in trying to get to the ball or the carrier. At least some effort is to be made to avert assaults that are not tolerated even in the prize ring.

One feature of the new rules is intended to "liberalize" them by allowing a man who has been taken out to return to the game in any subsequent period. There is now no excuse for a player to conceal a minor injury or exhaustion. He can leave the game and come back again later if his coach or trainer permits. From a medical standpoint the wisdom of this may be debatable. Minor injury as well as exhaustion calls for rest and recuperation rather than for further fatigue and possible aggravation of the harm done. It scarcely requires medical exhortation to remind coaches that unless players are "in the pink of perfection" they ought not to engage in athletic combats for which the continuous presence of a physician is now urged; for the survey experts freely admit that one of the most common sources of injury comes from allowing a player who has received a minor injury or is temporarily indisposed to remain in the game. Such a man is peculiarly susceptible to serious injuries that would otherwise be trivial.

The rules committee purposes to make definite recommendations to officials and coaches as to what they can do to reduce injuries still further and also to send a letter or recommendation to high schools and unorganized teams as to ways by which they may eliminate the number of serious injuries by better supervision and by prompt, intelligent attention to trivial or minor injuries. The importance of the employment of team physicians and of careful medical supervision is thoroughly appreciated. Sports writers have already heralded an expected "fifty per cent cut in football perils." Those experts who have sponsored the new rules believe that by the changes which have been made a great forward step has been taken, not only in checking the tendency toward increasing injuries but in making the game much safer than ever before. Of course, the committee adds, there will always be accidents and injuries in any game involving physical contact and speed; but the members of the committee believe that results will show that it has been possible to accomplish much by modification of the rules alone.

"SAVER OF MOTHERS"

In a glorious tribute to Ignaz Semmelweis, published in the March issue of the *Ladies' Home Journal,* Paul de Kruif, author of Microbe Hunters, again attacks members of the medical profession as responsible for unnecessary deaths from puerperal infection. Moreover, he repeats the claim, which Newsholme and others have shown to be unwarranted, that the death rate of mothers from puerperal infection in this country is higher than that of other civilized nations. Thus, he says: "Yet today in our country—with the exception of Chile and maybe one or two others—the death rate from child bed fever is higher than that of any civilized land."

The medical profession has rendered homage repeatedly to Semmelweis and Holmes and White and others whose names are associated with the development of the knowledge that strict asepsis will prevent the vast majority of cases of puerperal infection. It is rather sad, therefore, to have de Kruif argue that any considerable number of physicians do not know asepsis or that they are too busy to practice it. His cure for the situation is apparently to urge boycott for any physician in whose practice there occurs a death from puerperal infection. No doubt this would promptly bring about a boycott of every competent obstetrician, since even under the best of conditions with the most noted of authorities in charge, cases of puerperal infection do occur. Actual epidemics have developed in well established lying-in hospitals.

In his article de Kruif cites the statistics of the Lying-In Hospital in Chicago—where the maternity building is separate from gynecology—which indicate that 25,212 mothers were delivered, with one death from puerperal infection "caught in the hospital." Yet is there any actual evidence to indicate that every maternity hospital should be a separate building and that mothers are not safe in hospitals in which the maternity wards are a part of a general hospital? Medicine knows that infection is preventable, but disease prevention is costly and the suggestion that every baby should be born in an isolated maternity hospital is utopian. As well believe in the "Brave New World" of Aldous Huxley and have all of them raised from eggs in glass jars. Physicians may prevent infection from without the body but there are cases of infection from within.

The prevention of puerperal infection will not be realized by boycotts of doctors in whose practice cases occur. At this time, obstetric care in the United States for the vast majority of women is as good as if not better than in the majority of civilized countries. Therefore, it is unfair to the medical profession of this country to make them the scapegoats for promotion of any campaign or for building interest in the eulogy of a departed scientist. The life of Semmelweis needed no such false emphasis to attract intelligent readers. The *Ladies' Home Journal,* with its vast circulation and with the appeal that it has for several million women, does much to promote sound health education in problems affecting women. It should be able to accomplish this task without exaggeration. It can do more by educating women in the necessity for prenatal care, in the nature of proper obstetrics and in scientific infant feeding than by breaking down their confidence in their physicians.

FLOW OF BILE INTO THE INTESTINE

The rôle of bile in digestion is of such importance that contributions to the knowledge of its secretion and the factors concerned with its flow into the duodenum merit attention. The recent study of Puestow[1] deserves consideration for the novel experimental technic employed as much as for the addition to the available information on the mechanism of passage of bile into the intestine. In a three-stage operation, on dogs, a gastrojejunostomy was performed and the portion of the duodenal wall containing the opening of the ductus choledochus was brought to the external surface of the body wall. Here the segment of duodenum was cut lengthwise and the edges were sutured to the surrounding skin. The pancreatic secretion passed unimpeded into the distal portion of the duodenum, which remained in normal connection with the jejunum. With this preparation it was possible to make direct visual observations not only on the flow of bile after feeding various diets but also on the patency of the orifice of the choledochus and the behavior of the duodenal mucosa thus removed from direct contact with food materials. There was no flow of bile from the choledochus during fasting when the gallbladder was intact. The orifice of the duct was usually closed and the exposed segment of duodenal mucosa remained inactive so far as peristaltic movements or secretion were concerned. Under these conditions, the pressure in the common duct was between 140 and 170 mm. of bile. It is concluded that the sphincter mechanism at the end of the choledochus in the duodenal wall is effective in regulating the flow of bile into the intestine. The response to food was characteristic. Frequently the smell of food stimulated the slow flow of bile; inevitably the ingestion of food was followed by the appearance of bile from the duct. After two or three minutes the initial flow ceased but from ten to thirty minutes later bile again appeared and continued to flow for several hours.

These observations are considered to be a support for the view that there is a psychic or reflex stimulus to the expulsion of bile into the intestine. The bile was extruded in "brief oozes and spurts" and appeared at times to be influenced by the muscular contractions of the duodenum, which became active after food was ingested, as well as by the respiratory movements. Apparently the various kinds of foods used showed little difference in their influence on the flow of bile and the activity of the duodenum. The bile was dark brown, with a high viscosity at first, but as the flow continued it became lighter in color and less viscid. In an effort to stimulate bile flow by a local effect on the papilla of Vater, solutions of sodium chloride, sodium bicarbonate, hydrochloric acid, and magnesium sulphate were applied. This procedure as well as mechanical stimulation had no effect. On the other hand, the pronounced cholagogic action of bile salts was demonstrated after intravenous injection.

Removal of the gallbladder, on the other hand, resulted in a constant flow of bile in fasting animals. Feeding had little influence on the flow except to increase the quantity to a slight degree. The bile was light in color and watery after feeding, in contrast to the dark, viscid fluid observed when the gallbladder was intact. The opening of the duct apparently was constantly patent and the pressure in the duct was only 10 to 20 mm. of bile. Removal of the gallbladder exerted no influence on the response of the exposed duodenal segment to food.

The difficulty of formulating a satisfactory description of the mechanism whereby the hepatic secretion is ordinarily transferred to the intestine has been due, in no small part, to the anatomic situation in the region of the gallbladder, choledochus, duodenum and pancreas. As a result, experimental observations have been largely of an indirect nature. It is of importance, therefore, that the direct observation of the flow of bile permitted by the experimental technic of the Rochester investigator has substantiated in large measure the results obtained by other means. Only through such varied paths of approach can there be attained assurance of the probable mechanism in the normal intact organism.

---

Current Comment

EFFECT OF DIGITALIS BODIES ON THE VOMITING REFLEX

A moderately toxic dose of digitalis bodies induces attacks of vomiting, which continue and become more intense as the dose is increased. The vomiting may stop for several hours and then recur after the drug has been discontinued. However, the vomiting may cease as the drug is continued and other toxic effects appear in the form of frequent premature contractions of the heart or bigeminal rhythm. An experimental study was undertaken by Gold, Travell and Kwit[1] to determine whether it was possible by repeated injections of digitalis bodies to abolish the emetic action of the drugs, while at the same time increasing the extent of the cardiac poisoning. They injected digitoxin, ouabain and tincture of digitalis intravenously in dogs, varying the size of the dose, taking electrocardiograms at intervals before and after the injections, and in other ways observing the effects of the drugs on the vomiting reflex. Their experiments proved that after repeated doses of the digitalis bodies the vomiting reflex may be depressed so that a dose previously effective in producing vomiting becomes ineffective; the cardiac poisoning, however, continues to increase with the repeated doses, so that finally a toxic rhythm without vomiting is induced. The experiments did not give direct evidence as to the exact seat of the depression of the vomiting reflex, but this action is believed to be due to a peripheral action on the cardiac nerve fibers. It cannot be said how often such conditions are duplicated in the clinical use of digitalis bodies; however, clinicians should be cautious in relying on nausea and vomiting as a measure of the degree of cardiac poisoning. The continued use of large doses of digitalis bodies may depress the vomiting reflex and at the same time increase the intensity of the cardiac poisoning. After an initial period of vomiting, the continued administration of these drugs might even cause death without further vomiting.

ECONOMY AND THE PUBLIC HEALTH

At the present time this country is witnessing retrenchment in almost every field of human activity. The new policies are in part enforced by the exigencies of the financial situation; in no small measure they represent a return to programs of sane expenditures where orgies of unnecessary outlay had previously prevailed. The movement for economy has begun to invade the domain of governmental activities in the states as well as in the federal bureaus. It is, of course, proper that they should lead the way back to the practice of living within our national means. There may be an unfortunate fallacy, however, in the attempt to apply the pruning shears to all branches of governmental function. This applies notably to the services concerned with the public health. It sometimes happens that in times of stress the health of our people tends to suffer more than it may during periods of opulence. Hardly any one would argue that either the nation or a state has ever been unduly extravagant in expenditures for governmental hygiene. In fact, the most effective agencies in this field are even now scarcely well developed. Public opinion has not yet thoroughly grasped the usefulness of conservation through public hygiene and the fact that its cost to the taxpayer is saved many times over by the prevention of disease and death. The gains made in the elimination or curbing of such diseases as typhoid, yellow fever, malaria, smallpox and diphtheria—of the records of which the American medical profession may well be proud—must not be lost through a policy of false economy at this time. Health authorities must be enabled to perform their duties in an efficient manner. The menace of contagion, of stream pollution, of insanitary milk and food supply, of unregulated quarantine in world-wide travel must not be added to the other hardships now confronting the nation. Pointing out that reduced budgets are already carrying curtailed appropriations for public health departments, the president of the American Public Health Association, Dr. Louis I. Dublin, reminds us that it has been one of the "marvels of the last two years" that unemployment, decreased wages and lowered economic conditions have not affected health conditions and mortality. If public health is in a sense a purchasable commodity, our people should recognize expenditure for it as a wise outlay.

Association News

THE NEW ORLEANS SESSION

Cruises to Cuba, the Canal Zone and Central America

Members of the American Medical Association and their families are offered special cruises after the annual session to Cuban and Central American ports. A steamer belonging to the great white fleet of the United Fruit Company will sail from New Orleans, Saturday, May 14, at 11 a. m., for Havana, Cuba, Cristobal, Canal Zone, and Tela, Honduras, or Barrios, Guatemala, returning to New Orleans, Friday, May 27, at 8 a. m.

This trip has been arranged especially in response to the demand for a short vacation cruise. The number that can be accommodated is limited to eighty and all members desiring to join the party should make known their reservation requirements at once, as space will be assigned in the order in which applications are received. The fare, covering all expenses, varies from $140 to $220 per person, according to accommodations selected. All tickets are subject to a $5 U. S. war tax. The fares include meals and first-class stateroom accommodations for the entire cruise, steamer chairs, and shore excursion programs at the tropical ports—briefly, all expenses except gratuities, laundry, beverages and other items of a purely personal nature.

For further information and reservations, one may address the United Fruit Company, 111 West Washington Street, Chicago.

The Standard Fruit and Steamship Company will also schedule a special ship for physicians, their wives and friends. The ship will leave New Orleans on Saturday, May 14, for a twelve day trip to Havana, the Panama Canal and Puerto Cabezas, the banana port of Nicaragua. The rates vary from $97.50 to $127.50 per person, covering steamer, berth and meals. The steamer may be used as a hotel in Havana and Panama.

Several physicians have already booked. For further information address the Gardner-Coburn Tours, Bienville Hotel, New Orleans, or the Standard Fruit and Steamship Company, 224 Baronne Street, New Orleans.

MEDICAL BROADCAST FOR THE WEEK

American Medical Association Health Talks

The American Medical Association broadcasts on Monday from 12 noon to 12:05 p. m. over Station WBBM (770 kilocycles, or 389.4 meters) and other stations of the Columbia Broadcasting System, and on Wednesday and Friday from 2:25 to 2:30 p. m. over Station WBBM, Chicago.

The program for the week is as follows:

March 14. Safe Water for Rural Homes.
March 16. What Do You Know About That?
March 18. Milk, Poor or Pure.

There is also a fifteen minute health talk sponsored by the Association on Saturday from 11:15 to 11:30 a. m. over Station WBBM, Chicago.

The program for the week is as follows:

March 19. The Sign on Your House (continued).

Medical News

(Physicians will confer a favor by sending for this department items of news of more or less general interest: such as relate to society activities, new hospitals, education, public health, etc.)

ARKANSAS

Society News.—Dr. Sidney C. Barrow, Shreveport, La., among others, addressed the Tri-County Medical Society (Union, Columbia and Ouachita counties) in El Dorado, January 19, on "Radium and X-Ray."——Dr. Francis E. Utley, Cabot, entertained the Lonoke County Medical Society, February 10, in celebration of his fifty-first birthday.——The Arkansas County Medical Society was addressed, January 12, by Drs. Kingsley W. Cosgrove, Little Rock, and Jasper E. Neighbors, Stuttgart, on headaches and keloids, respectively.——Dr. Nona B. Ellis, Wilson, addressed the Mississippi County Medical Society, January 12, on "Management of Lobar Pneumonia."——The sixty-first anniversary of the Phillips County Medical Society was observed, January 26, in Helena; this society is said to be the oldest county society in the state.——Dr. William H. Mock, Prairie Grove, addressed the Washington County Medical Society, Fayetteville, February 2, on "Extra-Uterine Pregnancy."——Dr. Ray M. Balyeat, Oklahoma City, addressed the Hot Springs Academy of Medicine, February 2, on recent advances in allergy.

DELAWARE

Health at Wilmington.—Telegraphic reports to the U. S. Department of Commerce from eighty-three cities with a total population of 36 million, for the week ended February 27, indicate that the highest mortality rate (32.9) appears for Wilmington, and the rate for the group of cities as a whole, 12.9. The mortality rate for Wilmington for the corresponding week last year was 13.7, and for the group of cities, 14. The annual rate for eighty-three cities for the eight weeks of 1932 was 12.1, as against a rate of 14.3 for the corresponding period of the previous year. Caution should be used in the interpretation of these weekly figures, as they fluctuate widely. The fact that some cities are hospital centers for large areas outside the city limits, or that they have large Negro populations, may tend to increase the death rate.

DISTRICT OF COLUMBIA

Personal.—Dr. Daniel K. Shute, clinical professor emeritus of ophthalmology, George Washington University Medical School, received the honorary degree of doctor of science, February 22, at the bicentennial convocation of the George Washington University. Other honorary degrees also were conferred.

GEORGIA

Personal.—Dr. Frank B. Easley, Dalton, has been appointed director of district health unit number 2, composed of Catoosa, Gordon, Murray and Whitfield counties.——Dr. James W. Clements, Subligna, observed his ninety-first birthday, February 13.

Society News.—The Georgia Public Health Association was addressed at its annual meeting in Atlanta, January 22-23, among others, by Drs. Thomas H. D. Griffitts, Albany, on "Malaria Control for the Future"; Carl E. Rice, Rolla, Mo., "Trachoma Control in Georgia," and Guy G. Lunsford, Millen, "Typhoid and Sanitation." Dr. Ovid H. Cheek, Dublin, was elected president.——At the meeting of the Georgia Medical Society (Chatham County), January 12, Drs. Michael J. Egan, Jr., spoke on "Carcinoma of the Colon"; James C. Metts, "Spinal Cord Tumor with Operation and Discovery," and Thomas P. Waring, "Double Uterus with Operation." All the speakers were from Savannah.——Among speakers at the meeting of the Twelfth District Medical Society, Hawkinsville, January 22, were Drs. Major F. Fowler, Atlanta, on "Office Treatment of Venereal Diseases," and Edward B. Claxton, Dublin, "Gunshot Wounds of the Abdomen."——Dr. Amos J. Ayers, Atlanta, addressed the Fulton County Medical Society, among others, February 18, on "Clinical Laboratory Aids to Diagnosis in General Medicine."

ILLINOIS

Health Promotion Week.—A proclamation has been issued by the governor designating the week beginning April 24 and the day, May 1, as Health Promotion Week and Child Health Day, respectively. The days of the weeks will be known as Health Sunday, April 24; Nutrition Day, April 25; Dental Health Day, April 26; Immunization Day, April 27; Parental Inventory Day, April 28; Screen and Garden Day, April 29, and April 30-May 1, Child Health Day. Sunday, May 1, is officially designated National Child Health Day by the President of the United States, but the activities will take place largely on Saturday.

Chicago

Hospital News.—The first unit of the new municipal home for open cases of tuberculosis was recently opened. It is reported that about 400 patients can be accommodated in the institution, for which a building formerly occupied by the Chicago and Cook County School for Boys is being utilized, although the new unit will house only fifty.——A department of neurosurgery was established, January 20, at Presbyterian Hospital. Dr. Adrien H. P. E. Verbrugghen, formerly of Rochester, Minn., is the head of the department.

Society News.—Dr. Eugene T. Leddy, Rochester, Minn., addressed the Chicago Roentgen Society, March 9, on "X-Ray Treatment of Inoperable Carcinoma of the Breast."——Among others, Drs. Henry B. Thomas and Fred W. Hark addressed the Chicago Tuberculosis Society, March 10, on diagnosis and treatment of tuberculous joints.——The Chicago Orthopedic Society was addressed, March 11, by Drs. Eric Oldberg and Carroll C. L. Birch on "Spinal Tumors—Spasmodic Torticollis" and "Hemophilia," respectively.——Dr. Mortimer Diamond, among others, will address the Chicago Pathological Society, March 14, on "Fetal Calcification of the Myocardium."——A symposium on the public defender comprised the program of the meeting of the Chicago Academy of Criminology, March 10.

Branch Cancer Society Reorganized.—In order better to carry out the national program, the Illinois Branch of the American Society for the Control of Cancer was reorganized at a meeting, February 16, attended by representatives of the medical and dental professions, medical and dental colleges of Chicago, city and state health departments, Chicago Association of Commerce, Visiting Nurse Association and social agencies. It is intended that all approved organizations active in cancer education and research in Chicago and Illinois shall be properly represented in this branch, the purpose of which is to standardize approved methods of education, and to prepare and conduct a program in cancer education and research. Dr. Gilbert Fitz-Patrick was reappointed chairman for Illinois. Dr. William A. Evans was appointed chairman of the reorganization committee. Clarence C. Little, Sc.D., director, American Society for the Control of Cancer, as guest of honor, discussed cancer education. One of the special features of the Illinois program is the preparation of a book of pictures on lesions of the skin and mouth before and after treatment. The legends are being prepared by Drs. William E. Petersen and Francis E. Senear.

INDIANA

Society News.—Dr. Irvin Abell, Louisville, Ky., will address the Indianapolis Medical Society, March 15, on "Consideration of Some Modern Surgical Problems"; the program, March 22, will be given by Drs. William F. Clevenger and Howard B. Mettel on "Pathologic Mastoid: Complications, Diagnosis, Management" and "Diagnosis and Treatment of Allergic Conditions and Chronic Infections of the Respiratory Tract in Children," respectively. The society will be addressed, March 29, by Drs. Oscar N. Torian and Matthew Winters on "Anterior Poliomyelitis in Preparalytic Stage with Discussion of Treatment and Report of Seven Suspected Cases."

KANSAS

Undulant Fever.—Two cases of undulant fever, reported in Junction City recently, caused the city commissioners to rule that all dairymen selling milk in Junction City must have their cows tested for contagious abortion.

Society News.—William J. Burns, executive secretary, Wayne County Medical Society, Detroit, addressed the Shawnee County Medical Society, March 7, on "Modern Functions of the County Medical Society."——A motion picture on traumatic surgery was shown before the Labette County Medical Society, January 27.——The Miami County Medical Society was addressed in Paola, January 12, by Drs. George E. Knappenberger and John H. Ogilvie, Kansas City, Mo., on "Diagnosis and Treatment of Peptic Ulcer" and "Cystic Diseases of the Breast," respectively.——Dr. Robert Lee Hoffmann, Kansas City, addressed a joint meeting of the Mitchell County Medical Society and the Solomon Valley Medical Society, January 13, on "Significance of Blood in the Urine." Dr. Ray M. Balyeat, Oklahoma City, spoke on allergic diseases.——The Wyandotte County Medical Society was addressed, March 1, by Drs. Albert J. Rettenmaier on "Fibroid Tumors," and Fred E. Angle, agranulocytosis.——At a meeting sponsored by the Crawford County Medical Society, February 18, the speakers included Drs. Clinton K. Smith and A. Morris Ginsberg, Kansas City, Mo., on "Transurethral Prostatomy" and "Present Conception of the Heart in Exophthalmic Goiter," respectively.——The Sumner County Medical Society was addressed, February 18, by Dr. Paul C. Carson, Wichita, on "Forms of Encephalitis and Convulsions in Children"; Dr. George E. Cowles, Wichita, also spoke.——A joint meeting of the Wichita Dental Society and the Sedgwick County Medical Society will be addressed, March 15, by H. C. Holmes, D.D.S., and Edwin H. Terrill, Wichita, on "The Dentist of Today" and "Relation of Certain Vitamins and Minerals to Nutrition," respectively.

KENTUCKY

Bills Introduced.—S. 434 and H. 817 propose to make it unlawful for public school authorities to permit minor students to be subjected to either medical or physical examinations over the written objections of the person or persons having legal custody of such minors, if such objections are accompanied by written statements of licensed physicians certifying as to the students' physical condition and good health.

LOUISIANA

Hospital News.—The Mary J. Walker unit of the Greenwell Springs Sanatorium, Zachary, has recently been completed. The new building has a capacity of 100 beds and has been made possible through a bequest of the late Mrs. Mary J. Walker, Lake Province. The sanatorium is under the jurisdiction of the Louisiana State Tuberculosis Commission.

University News.—A three months' course in tropical medicine was begun, March 1, at the Tulane University of Louisiana School of Medicine, New Orleans, for public health officers, physicians who expect to practice in the tropics, and selected senior medical students.——Dr. Charles A. Bahn has been appointed professor of ophthalmology in the graduate department of the Louisiana State University Medical Center.

Institute on Tuberculosis.—A case finding institute on tuberculosis was held in New Orleans, February 17-18, by the Tuberculosis and Public Health Association of Louisiana in cooperation with the state board of health. The program included a demonstration of the technic of tuberculin testing and a study of x-ray plates, lectures and round table discussion. Among the speakers were Drs. Kendall Emerson, New York, William C. White, Washington, D. C., and Horton R. Casparis, Nashville, Tenn.

MASSACHUSETTS

Personal.—Dr. Augustus Thorndike, Jr., Boston, has been appointed surgeon in the department of hygiene, Harvard University Medical School; he will also direct the medical activities in athletics. Dr. Thorndike will succeed Dr. Thomas K. Richards, whose resignation will become effective in the fall.

Society News.—The New England Pediatric Society was addressed, February 26, by Drs. Lewis Webb Hill, Boston, on "The Eczema Problem," and James S. Plant, Newark, N. J., "Promise of Psychiatry."——"Certain Problems in Diseases of Women" was the subject of Dr. Henry T. Hutchins, Boston, before the Belmont Medical Society, February 26.——Dr. Howard Moore, Boston, addressed the New England Physical Therapy Society, February 17, on "Treatment of Shoulder Conditions by Physical Therapy."——At the meeting of the New England Roentgen Ray Society, February 19, Drs. George Levene, Norwood, and William D. Reid, Boston, spoke on "Anatomic and Functional Diagnosis of Heart Disease by Means of the Roentgen Ray."——Dr. Theodore C. Greene, Peiping, China, addressed the Boston Medical History Club, February 15, on "Ancient and Modern Practice of Medicine in China: Medical Experiences in City and Country," and Dr. Arthur B. Lyon, Boston, "Daniel Whistler and the First Treatise on Rickets, 1645."——"Medical Publicity by Organizations and Individual Physicians" was the general topic discussed by Drs. Morris Fishbein, Chicago, and Iago Galdston, New York, March 10, before the New England Medical Council at the Boston Medical Library.

MICHIGAN

University News.—A chair of internal medicine is to be established at the Detroit College of Medicine and Surgery by the will of Dr. James Cleland, Jr. The bequest to the college becomes effective after the death of Dr. Cleland's wife.

Personal.—Dr. Hugo Erichsen, Birmingham, observed his fiftieth anniversary in the practice of medicine, March 2.——George B. Darling, Detroit, has been appointed associate executive director of the W. K. Kellogg Foundation, effective February 15.——Dr. William Arkell Browne, Baltimore, has been appointed health officer of the recently organized Oceana-Lake-Newaygo health unit, with headquarters at White Cloud.

Detroit's Swimming Pools.—In 1931, 78.2 per cent of Detroit's swimming pools were free from bacteria, as compared with *1925* when only *27* per cent of the samples showed a zero bacterial count. In 98.9 per cent of the samples of swimming pool water taken during 1931, B. coli was not found. Ford Hospital pool heads the list of pools not showing organisms of the B. coli group for a period of more than two years; it has been free from these organisms for more than five years. The number of pools in operation in the city in 1931 was more than double the number maintained in 1925.

Child Welfare Conference.—The Detroit District Extension of the White House Conference for Child Care and Protection will be held in Detroit, March 18-19, with headquarters at the Statler Hotel. The purposes of the conference will be to disseminate information on medical service, public health and administration, and the education and training of the handicapped; to present Detroit's current efforts to meet the requirements of the Children's Charter, and to foresee whatever may be revealed as the next steps in this matter. Assisting in the conference will be the Wayne County Medical Society, the board of health, child care agencies, and the education department.

Courses in Hygiene and Public Health.—Special week-end public health institutes in connection with the summer session at the University of Michigan will begin June 24 and continue through July 30, the week-end of July 1 being excluded. All branches of interest to public health workers will be emphasized. The speakers included in the program are Dr. Iago Galdston, New York; Mr. C. C. Young, Lansing; Drs. Mazyck P. Ravenel, Columbia, Mo.; Clyde C. Slemons, Lansing; Eugene L. Bishop, Nashville, Tenn.; William W. Peter, New York; Henry F. Vaughan, Dr.P.H., Detroit, and Dr. William J. V. Deacon, Lansing. The fee is $3 for each week-end session or $15 for the complete course. The regular summer session courses will begin June 27 and continue through August 5. Subjects under these courses will include methods and materials in health education, public health law and administration, administration and organization in public health nursing, and mental hygiene. For further information address Nathan Sinai, Dr.P.H., acting director, division of hygiene and public health, University of Michigan, Ann Arbor.

Society News.—Dr. Irving W. Greene, Owosso, among others, addressed the Shiawassee County Medical Society, February 11, on "Diagnosis and Treatment of Diabetic Acidosis and Coma"; Dr. Reed W. Teed spoke on "Malnutrition of Infants."——The speakers before the Washtenaw County Medical Society, February 18, included Dr. Colin C. McRae, Ann Arbor, on "Experimental Observations on Appendiceal Obstructions."——At a meeting of the Ionia-Montcalm Medical Society, February 9, in Belding, Dr. Alexander M. Campbell, Grand Rapids, spoke on "Management of Certain Obstetrical Complications"; Dr. William J. Butler, Grand Rapids, "Intravenous Urography," and Phillipp Northrup, D.D.S., "Reflex Disturbances of Impacted Teeth."——The Calhoun County Medical Society was addressed, March 1, by Drs. Louis J.

Hirschman, Detroit, and Awra A. Hoyt, Battle Creek, on "Colonic Dysfunction versus Colitis" and "Diphtheria Immunization," respectively.——The clubrooms and library of the Kent County Medical Society were recently opened with a dinner and housewarming. The new quarters are on the third floor of the Medical Arts Building in Grand Rapids. Among other speakers, Dr. Frederick C. Warnshuis gave a history of the society since 1902.——Dr. Angus McLean, Detroit, addressed the West Side Physicians Association, February 18, on "Veterans' Medical Care."——John H. Muyskens, Sc.D., Ann Arbor, addressed a joint meeting of the Wayne County Medical Society and Grace Hospital, March 8, on "Speech Defects—Cause, Prevention and Correction."

MINNESOTA

Personal.—Dr. Hugh Cabot, Rochester, will address the Abernethian Society, St. Bartholomew's Hospital, London, England, April 14, on "Further Travels with the North American Indians."——Dr. Joseph A. Roy was recently elected mayor of Red Lake Falls.

Violation of Basic Science Law.—Mitchell Jurdy, listed in the 1931 Minneapolis city directory as a naturopathic physician, pleaded guilty to practicing healing without a basic science certificate, February 19. Judge Reed of the district court, Minneapolis, sentenced Jurdy to one year in the city workhouse. The sentence was stayed for one year, pending the good behavior of the defendant and his compliance with the medical laws of the state. Jurdy treated a patient suffering with epilepsy, it was claimed. The father of the patient testified that they had met Jurdy at the "Riley Long Life Health Club," where Jurdy lectured. On the day of the sentence, Jurdy told a representative of the state board of medical examiners that he has severed all connections with the naturopathic organization.

NEW JERSEY

Bill Introduced.—S. 204 proposes to accord physicians treating persons injured in accidents, liens on any judgments or settlements obtained by the injured persons by reason of their injuries.

Society News.—Drs. Philip J. Lipsett and William G. Doran, New York, addressed the Hudson County Medical Society, Jersey City, March 1, on "Acute Intra-Abdominal Diseases and Their Treatment" and "Early Symptoms of Congenital Dislocation of the Hip Joint," respectively.——Drs. Arthur First, Philadelphia, and Arthur L. Stone, Camden, addressed the Camden County Medical Society, Camden, March 1, on "Newer Concepts of the Biologic Tests for Pregnancy" and "The Profession's Responsibility in Matters of Public Health," respectively.——Dr. Grafton Tyler Brown, Washington, D. C., addressed the Atlantic County Medical Society, Atlantic City, March 11, on "Seasonal Hay Fever."——Mr. F. Edward Whitehead, River Edge, has been appointed executive secretary of the Bergen County Medical Society, a newly created position. He began his work, March 1.——Drs. Morris Fishbein, Chicago, and Ira S. Wile, New York, addressed a joint meeting of the Bergen and Passaic county medical societies in Paterson, March 8, on "The Changing Nature of Medical Practice" and "Child Behavior as a Medical Problem," respectively.

NEW YORK

Bills Introduced.—S. 1217 and A. 1587, to amend the law authorizing county and city boards of health to provide facilities for the treatment of venereal diseases, propose (1) to appropriate $250 toward the cost of initial installation of each such clinic as may be established by law and (2) to authorize the payment by the state of one half of the annual cost of the maintenance and operation of each such clinic. S. 1283 and A. 1546 propose to accord liens to hospitals treating persons injured in accidents, on any judgments or settlements obtained by such persons by reason of their injuries. S. 1343 proposes to create a board of hair dressers and cosmetologists and to regulate the practice of hair dressing and cosmetology. S. 1469, to amend the workmen's compensation act, proposes apparently to omit that provision of the act permitting an injured employee or an insurance carrier to select physicians to be present at any physical examination of an employee ordered by the industrial board or by the industrial commissioner. S. 1470 and A. 1725, to amend the workmen's compensation act, propose to permit an injured employee to elect to be treated at his employer's expense in a charitable or municipal hospital. S. 1468 and A. 1726, to amend the workmen's compensation act, propose to define "charitable and municipal hospitals" as referred to in S. 1470 and A. 1725. A. 1729 proposes to create a board of dental technicians and to regulate the licensing of master dental technicians and the operation of dental laboratories. A. 1733 proposes to provide that all cosmetics be labeled to show that they are not injurious, the name of the compounders and the dates of compounding, and to require manufacturers of cosmetics to file with the state public health department certain statements as to their formulas.

New York City

Sixth Harvey Lecture.—Dr. Leslie T. Webster, Rockefeller Institute, will deliver the sixth Harvey Society Lecture at the New York Academy of Medicine, March 17, on "Experimental Epidemiology." Officers of the society recently elected are as follows: Drs. Alfred F. Hess, president; Haven Emerson, vice president; Thomas M. Rivers, treasurer, and Edgar Stillman, secretary.

Promotions at New York University.—Four members of the staff of New York University and Bellevue Hospital Medical College were promoted in February as follows:

Dr. Frank C. Combes, Jr., to assistant clinical professor of dermatology and syphilology.
Dr. Henry C. Falk to clinical professor of gynecology.
Dr. Onslow A. Gordon, Jr., to associate professor of gynecology.
Dr. Francis W. Sovak to clinical professor of gynecology.

Personal.—Dr. Max Einhorn was the guest of honor at a dinner celebrating his seventieth birthday, January 9, given at the Hotel Astor by the staffs of the Lenox Hill and Postgraduate hospitals and members of the German Medical Society and the International Medical Club of America.——Dr. William B. Coley, chief surgeon of the New York Central Railroad, retired, January 1, after thirty-five years of service and was succeeded by his son, Dr. Bradley L. Coley.

Society News.—Drs. Albert A. Epstein, William Barclay Parsons, Jr., and Charles Gordon Heyd addressed the Medical Society of the County of New York, February 29, on diseases of the thyroid gland.——Drs. George W. Crile, Cleveland, and Edwin A. Riesenfeld addressed the Harlem Medical Association, March 2, on "Factors Determining the End-Results of Surgical Treatment of Hyperthyroidism" and "Postural Treatment for Intracranial Hemorrhage in the New-Born," respectively.——Drs. Herman Goodman and Herbert S. Abel, among others, addressed the New York Physical Therapy Association, March 2, on "Hot and Cold Quartz Tubes: Reaction of the Skin in Health and Disease."——A special meeting of the New York Academy of Medicine under the auspices of its committee on public health relations and the Committee on Costs of Medical Care was held, March 9, with the following speakers: Drs. Richard M. Smith, Boston, "Outstanding Facts from the Studies of the Committee on Costs of Medical Care"; Allon Peebles, Ph.D., Washington, D. C., "Unevenness of Distribution of the Costs of Medical Care," and Dr. Nathan B. Van Etten, "Social and Economic Problems Facing the Medical Profession."

OHIO

Lectures on Otology.—Dr. Erich Ruttin, Vienna, Austria, will give a series of lectures and demonstrations in otology in Cincinnati, March 21-25. Those interested may receive further information from Dr. Harris H. Vail, 919 Carew Tower, Cincinnati.

Personal.—Dr. Charles H. Creed, head of the bureau of examination and classification at the Ohio State Penitentiary, Columbus, has been appointed superintendent of the Athens State Hospital to succeed the late Dr. John H. Berry.——Drs. Ralph W. Staley, Ernest O. Swartz and Henry B. Freiberg were made assistant professors in the department of urology at the University of Cincinnati School of Medicine in February.

University News.—Dr. Esmond R. Long, professor of pathology, University of Chicago, delivered the annual lectures in pathology at the Ohio State University College of Medicine, February 26. The first lecture was given before the faculty and student body on "A Survey of the Origins of Modern Pathology" and the second to the faculty, the students and the medical profession of Columbus on "The Exudative Phenomena in Tuberculosis."

Society News.—Drs. Fred W. Rankin and Byrl R. Kirklin, Rochester, Minn., addressed the Toledo Academy of Medicine, February 5, on "Surgical Treatment of Cancer of the Colon," and "Roentgenologic Diagnosis of Malignant Lesions of the Colon," respectively. The academy held an all-day clinic at the Lucas County Hospital, March 4, with Dr. Pol N. Coryllos, New York, as guest demonstrator on operative technic in chest conditions. Dr. Coryllos addressed the general meeting of the academy on "Causes and Prevention of Cardiopulmonary Complications in Chest Surgery After Tuberculosis."——Dr. Mont

R. Reid, Cincinnati, addressed the Summit County Medical Society, Akron, March 1, on "Surgery of the Sympathetic Nervous System."——Dr. Herbert Fox, Philadelphia, addressed the Cincinnati Academy of Medicine, March 7, on "Arteriosclerosis: Its Causation and Significance According to Comparative Anatomy." The Cincinnati Oto-Laryngological Society will meet with the specialty section of the academy, March 28, to hear George Oscar Russell, Ph.D., Columbus, give an address on "New Light on Interior Laryngeal Function Through Sound Movies Thereof."——Dr. Vernon C. Rowland, Cleveland, addressed the Montgomery County Medical Society, Dayton, March 4, on "Differential Diagnosis of Chronic Colitis."

OKLAHOMA

Society News.—At a joint session of the Woods and Alfalfa county medical societies, Alva, January 26, speakers were Drs. Philip M. McNeill on "Nontuberculous Infections of the Lungs"; Henry H. Turner, "Interrelationship of Endocrinology and Neurology," and Horace Reed, "Differential Diagnosis of Acute Appendicitis." All speakers were from Oklahoma City.

OREGON

Society News.—Mr. Fred Ross, attorney, addressed the Portland City and County Medical Society, March 2, on "The Workmen's Compensation Act in Relation to the Medical Profession." At a joint meeting with the Portland District Dental Society, February 17, speakers were Drs. Homer P. Rush, on "Systemic Manifestations of Dental Focal Infection"; Ralph A. Fenton, "Manifestations of Dental Sepsis Relative to Eye, Ear, Nose and Throat," and Byron E. Loomis, D.D.S., "Oral and Dental Diagnosis."——The Portland Medical Hospital took possession of a new $100,000 building, January 13; the present capacity is seventy-five beds, to which it is planned to add twenty in the future.

PENNSYLVANIA

State Society's Essay Prize Awarded.—Dr. William A. Lell, intern at the Graduate Hospital, University of Pennsylvania, Philadelphia, received a prize of $100 in a contest sponsored by the Medical Society of the State of Pennsylvania for the best essay on "How to Diminish Deaths from Cancer in Pennsylvania." This contest was inaugurated early in 1931 and was open to any intern on duty in the state, Dec. 31, 1931. A similar contest was held for nurses with a prize of $50 offered for an essay on "How a Nurse Can Help Diminish Deaths from Cancer in Pennsylvania." The contests were the climax of several years' endeavor on the part of the society's commission on cancer to build up in the minds of those teaching young physicians and nurses in hospitals the value of their opportunity for impressing the need for early recognition of the signs of cancer. Dr. Lell's essay presented a plan for the establishment of six cancer clinics to be maintained by the commonwealth, where any person might obtain examination to learn whether he is suffering from the disease.

Philadelphia

Anniversary Meeting.—The Woman's Medical College of Pennsylvania held an open scientific meeting at the college building, March 11, marking the eighty-second anniversary of its founding. Dr. Edward B. Meigs, Washington, D. C., was the speaker of the evening on "The Nutritive Value of Milk."

Robert Koch Anniversary.—The section on medical history of the College of Physicians of Philadelphia will hold its stated meeting, March 14, in cooperation with the Henry Phipps Institute, the Philadelphia Health Council and Tuberculosis Committee and the Philadelphia Association of Tuberculosis Clinics to commemorate the fiftieth anniversary of the discovery by Robert Koch, March 24, 1882, of the tubercle bacillus. Addresses were made by Drs. Henry R. M. Landis, on "Reception of Koch's Announcement in the United States"; Theobald Smith, Princeton, N. J., "Koch's Views on the Stability of Species Among Bacteria"; Lawrason Brown, Saranac Lake, N. Y., "What Koch Meant to Tuberculosis," and Damaso de Rivas, "Personal Reminiscences of Robert Koch."

Society News.—Dr. Henry K. Pancoast addressed the Philadelphia Roentgen Ray Society, March 3, on "Roentgenological Studies of Tumors of the Gastro-Intestinal Tract."——Among speakers before the Obstetrical Society of Philadelphia, March 3, were Drs. Clifford B. Lull, who gave "A Preliminary Report on the Use of Barbiturates with Ether by Rectum," and Charles H. Frazier and Henry F. Ulrich, "Thyrotoxicosis Complicating Pregnancy."——Dr. Edward F. Corson, delivered the postgraduate seminar of the Philadelphia County Medical Society, March 4, on "Differential Diagnosis of Syphilitic and Nonsyphilitic Eruptions." Dr. Martin E. Rehfuss gave the lecture, March 11, on "Diagnosis and Treatment of Colon Infections."——Dr. Joseph C. Doane addressed the Philadelphia Medical Examiners' Association, March 7, on "Vascular Diseases of the Extremities and Their Relation to Insurance."——Drs. Robert H. Ivy and Lawrence Curtis addressed the Philadelphia Academy of Surgery, March 7, on "Salivary Duct Calculi," and Dr. Joseph L. Magrath, Upper Darby, on "Surgical Shock."——A symposium on sinusitis in children was held before a joint meeting of the Philadelphia Pediatric Society and Philadelphia Laryngological Society, March 8, with Drs. John D. Donnelly, Bala-Cynwyd, Herman B. Cohen, Willis F. Manges and Gabriel Tucker as participants.——Drs. Harvey M. Watkins, Polk; Mary M. Wolfe, Laurelton, and Robert A. Matthews presented a symposium on mental deficiency before the Philadelphia Psychiatric Society, March 11.——Dr. Seth A. Brumm was elected president of the Philadelphia Association of Tuberculosis Clinics at its meeting, February 24. Dr. David R. Lyman, Wallingford, Conn., addressed the society on the tuberculosis death rate as affected by the industrial depression.

SOUTH CAROLINA

Hospital Burned.—Fire recently destroyed completely the Majority Hospital for Negroes at Union. An effort is being made by both white and colored citizens to restore the hospital as soon as possible. Believing that physicians or hospitals in other parts of the country may have equipment for wards and operating room which may have been discarded for newer equipment, but is in good condition, those interested have requested donation of such material for the use of the hospital. Mr. Allan Nicholson, a newspaper editor of Union, is in charge of the movement to restore the hospital, and correspondence may be addressed to him.

TEXAS

Society News.—Drs. William M. Crawford and Walter B. West addressed the Tarrant County Medical Society, Fort Worth, February 2, on lymphosarcoma of the mediastinum and injuries to the head, respectively.——The Northwestern Texas District Medical Society met, March 8, in Dallas. Among the speakers announced were Drs. Joseph F. McVeigh and William S. Horn, Fort Worth, on "Malignant Endocarditis" and "Angina Pectoris Associated with Pernicious Anemia," respectively, and George M. Underwood and Arthur J. Schwenkenberg, Dallas, on "Diagnosis and Treatment of Jaundice" and "Nervous Breakdown Precipitated by Recent Economic Crisis," respectively.——Drs. Howard R. Dudgeon, Waco, and Marion M. Brown, Mexia, addressed the Navarro County Medical Society, Corsicana, January 4, on "Cancer of the Colon" and "Spinal Anesthesia," respectively.——Dr. Cleve C. Nash, Dallas, addressed the Harris County Medical Society, Houston, January 20, on diagnosis and treatment of brain tumors.——Drs. George Raworth Williams and James Shirley Sweeney addressed the Dallas County Medical Society, January 28, on "Kidney Pain" and "Pancreatitis and Diabetes Mellitus," respectively. A symposium on cancer was presented, March 10, by Drs. James M. Martin, John L. Goforth and Charles L. Martin.

UTAH

Annual Registration Due April 1.—All practitioners of medicine and surgery holding licenses in Utah are required to register annually on or before April 1, with the department of registration, and to pay a fee of $3. If a licentiate neglects to register within from ninety days to six months after April 1, his license can be revoked and will be reinstated thereafter only on his paying the delinquent registration fees and an additional year's fee as a penalty.

VIRGINIA

Bill Introduced.—H. 256 proposes to create a division of barber examiners in the state health department and to regulate the practice of barbering.

WISCONSIN

Board to Consider Reciprocity Applications.—The Wisconsin State Board of Medical Examiners will hold a special meeting, April 6, at the Hotel Schroeder, Milwaukee, to consider applications for licenses by reciprocity only.

Society News.—Drs. Campbell C. Edmondson, Waukesha, and Russell M. Kurten, Racine, addressed the Racine County Medical Society, January 21, on diabetes and "Physiology of the Sex Cycle," respectively. County Judge J. Allan Simpson spoke on "Admission of Patients to County Hospitals as County Charges."——Dr. Dallas B. Phemister, Chicago, addressed the Medical Society of Milwaukee County, February 12, on gallstones.——Dr. Owen H. Wangensteen, Minneapolis, made an address on "Diagnosis and Treatment of Acute Intestinal Obstruction" before the Milwaukee Academy of Medicine, February 16.——Dr. Glenn J. Greenwood, Evanston, Ill., addressed the Outagamie County Medical Society, Appleton, February 23, on "Middle Ear Infections in Children."

WYOMING

Annual Registration Due April 1.—All practitioners of medicine and surgery licensed to practice in Wyoming are required by law to register on or before April 1, with the secretary of the board of medical examiners, and to pay a fee of $2.50. If a licentiate fails to pay the fee within three months after April 1, his license can be annulled, and if annulled it will be restored to him only on his paying the stated fee, plus $5 as a penalty.

GENERAL

Society News.—Dr. John F. D. Cook, Langford, S. D., was elected president of the Northwest Regional Medical Conference at the annual meeting in St. Paul, January 24, and Vernon D. Blank, Des Moines, was elected secretary. The states included in this group are Minnesota, Wyoming, Ohio, Illinois, Iowa, Wisconsin, Nebraska, North Dakota and South Dakota.——Dr. Alexander B. Dancy, Jackson, Tenn., was named president-elect of the Mid-South Postgraduate Medical Assembly at its meeting in Memphis, February 11. Dr. Lowry H. McDaniel, Tyronza, Ark., became president. Memphis was selected as a permanent meeting place.——The Radiological Society of North America has set the date of its next meeting for November 28-December 2, in Atlantic City.

Annual Meeting of College of Physicians.—The sixteenth annual clinical session of the American College of Physicians will be held in San Francisco, April 4-8, with general headquarters at the Palace Hotel, and under the presidency of Dr. Solon Marx White, Minneapolis. This is the first meeting of the college to be held on the Pacific Coast, and it is planned to present through clinics and demonstrations the disease entities which are more or less peculiar to western America. To this group belong coccidioides, undulant fever, relapsing fever, Rocky Mountain spotted fever, tularemia, amebiasis, poisoning from spider bite, mussel poisoning and botulism. Programs have been arranged for those interested in the fields of cardiovascular, gastro-intestinal, endocrine diseases and diseases of the hematopoietic system. There will be symposiums on diseases of the kidney, tropical diseases and pulmonary diseases, and, two days during the session, clinicopathologic conferences will be held. Wednesday, April 6, there will be a symposium dealing with the "Medical History of Western America," including papers on medicine in Mexico, Peru, early California and in the Northwestern states, and plans for Friday call for a symposium on the "Anatomical Traditions of the Renaissance and Their Relation to the Modern Teaching of Anatomy." A symposium on "Ten Years' Experience with Insulin" will also be held. Various exhibits of rare medical prints and collections are being arranged. An extensive program of scientific papers will be presented by men prominent in their respective fields. The annual banquet of the college will be April 7. Dr. Arthur L. Bloomfield, San Francisco, will act as toastmaster, and Dr. Charles J. Singer of the University of London, London, England, will deliver an address on "A Great Country Doctor."

Medical Bills in Congress.—*Changes in Status:* S. 695 has been recommitted to the Senate Finance Committee. The bill, proposing a reduction in payments to veterans under the Disabled Emergency Retirement Act while they are being maintained in institutions by the Veterans' Administration, had previously been favorably reported to the Senate. S. 572, the Jones rural health, and maternity and child hygiene bill, has been ordered favorably reported, with amendment, by the Senate Commerce Committee, by a vote of 12 to 9. The proposed amendment strikes out all after the enacting clause and inserts in lieu thereof the provisions of a bill introduced by Senator Jones during the Seventy-First Congress, S. 255, providing for the promotion of the health and welfare of mothers and infants. S. 1975 has been favorably reported to the Senate, without amendment, to amend an act entitled "An Act to recognize the high public service rendered by Major Walter Reed and those associated with him in the discovery of the cause and means of transmission of yellow fever," by including Roger P. Ames among those honored by the act. H. R. 4577, proposing to extend hospital and home facilities to veterans of the Confederate Army and Navy, has been recommitted to the House Committee on Military Affairs. The bill had previously been favorably reported to the House. *Bills Introduced:* S. 3769, by Senator King, Utah, to amend the Disabled Emergency Officers' Retirement Act by requiring beneficiaries to have served six months or more as members of the military or naval establishments, between April 6, 1917, and Nov. 11, 1918, and by requiring that the disability for which retirement is sought shall have been incurred as a result of war service between April 6, 1917, and Nov. 11, 1918. S. 3849, by Senator Trammell, Florida, and H. R. 9969, by Representative Green, Florida, to erect a 200 bed addition to the veterans' hospital, Lake City, Fla. S. 3853, by Senator Bingham, Connecticut, to regulate interstate and foreign commerce in poisonous volatile substances intended for household consumption. S. 3865, by Senator Bulkley, Ohio, to provide treatment in marine hospitals for persons belonging to the Steamboat Inspection Service whose chief duties are inspection of vessels. S. 3884, by Senator Capper, Kansas, to provide for the further development of vocational education in the several states and territories. H. R. 9450, by Representative Johnson, Oklahoma, to provide additional compensation for veterans entering service prior to Nov. 11, 1918, who suffered the loss of the "use of a creative organ or one or more feet or hands as the result of personal injury received or disease contracted in active service in line of duty after April 6, 1917, and before discharge from such service." H. R. 9485, by Representative Harlan, Ohio, to authorize construction at the Veterans' Administration Home, Dayton, Ohio. H. R. 9838, by Representative Hess, Ohio, to construct a veterans' hospital and regional office in Cincinnati. H. R. 9890, by Representative Thatcher, Kentucky, to construct a hospital at Fort Knox, Kentucky. H. R. 10042, by Representative Connery, Massachusetts, to recognize the high public service rendered by soldiers who volunteered and served in trench fever experiments in the American Expeditionary Forces. H. R. 10052, by Representative Seiberling, Ohio, to provide for federal cooperation with the several states and territories in the physical restoration, education, vocational guidance and vocational education of "any person below the age of twenty-one years who by reason of physical defects or infirmities, whether congenital or acquired by accident, injury, or disease, are or may be expected to be totally or partially incapacitated for participation in the educational and vocational activities expected of a normal person."

PHILIPPINE ISLANDS

Campaign for Eyesight Conservation.—An active campaign for the correction of eye defects and conservation of vision was recommended to the house of delegates of the Philippine Islands Medical Association in December by a committee on conservation of vision created by the house in 1927. Statistics collected by the committee showed that blindness and defective vision are prevalent among Filipinos and that in many cases these handicaps could be prevented by proper care. In one study of about 1,800 cases of blindness, it was found that 27 per cent were caused by cataract and 25 per cent by physical injuries with subsequent infections and improper treatment. Of 7,996 industrial accidents reported to the labor office of the islands, 222 involved the eyes. It was said that the office recommended the use of goggles but that there is no law requiring it. The committee recommended, as features of its campaign, popular education, strict enforcement of regulations concerning communicable diseases, establishment of more eye clinics in the provinces, instruction of medical personnel and encouragement of all health agencies to take part in the campaign. Among other activities the committee has sponsored legislation to require physicians, nurses and midwives to use preventive measures against ophthalmia neonatorum, but this is still pending in the legislature. Dr. Antonio S. Fernando is chairman of the committee, and the members are Drs. Rafael Villafranca and Conrado D. Ayuyao.

CANADA

Personal.—Dr. Jabez Henry Elliott has been appointed professor of the history of medicine at the University of Toronto to succeed Dr. John T. Fotheringham, who retired in June, 1931. For the past six years Dr. Elliott has been a special lecturer in medicine at the university.——A scroll of recognition was recently presented to Dr. Velyien Ewart Henderson, professor of pharmacy and pharmacology, University of Toronto Faculty of Medicine, by the International Anesthesia Research Society in appreciation of his work in anesthesia.——Dr. Rosario Fontaine has been appointed professor of medical jurisprudence and toxicology at the University of Montreal Faculty of Medicine to succeed the late Dr. G. Wilfrid Derome.

Saskatchewan Cancer Clinics.—Two clinics for the diagnosis and treatment of cancer have recently been opened in Saskatchewan, at the Regina General Hospital and the Saskatoon City Hospital, said to be the first of their kind in the dominion. This action is part of a concerted attack on cancer in the province, which began with the appointment of a cancer commission in June, 1930, under authority of legislation passed in the previous session of the legislature. This commission was empowered to carry on a campaign of public education for control of cancer, to investigate the problem in the province, to establish diagnostic clinics and to buy radium to the amount of $115,000 (The Journal, April 11, 1930, p. 1332). Admittance to the clinics may be secured only through recommendation by a medical practitioner. A fee of $10 will be charged for the examination of a patient and other fees will be payable to the hospital for hospital service, to the commission for radiotherapy and to the surgeon for any surgical measures. Staffs will be made up of the chiefs of the various departments of the hospital services, it was announced.

Lectures at Toronto.—A series of lectures of special interest to the practitioner has been presented during the winter months by the Academy of Medicine of Toronto. Following are the speakers and their subjects:

Dr. Goldwin W. Howland, "The Pituitary as an Endocrine Gland."
Dr. Kenneth G. McKenzie, "The Pituitary as a Brain Tumor."
Dr. Alan G. Brown, "Practical Considerations of Disturbances of the Thyroid Glands in Infancy and Childhood."
Dr. Joseph A. Gilchrist, "The Challenge of the Pancreas."
Dr. Francis J. O'Leary, "Ovarian and Placental Therapy."
Dr. Ray F. Farquharson, "Treatment of Anemia and Associated Conditions by Liver and Extracts of Liver and Stomach."
Dr. Cecil O. Young, "Thyroid Gland: Medical Aspect; Hyperthyroid Conditions."
Dr. Andrew Almon Fletcher, "Hypothyroidism and Low Metabolic Rates."
Dr. Harold G. Armstrong, "Thyroid Gland; Surgical Aspect."

FOREIGN

Centenary of British Medical Association.—The centenary meeting of the British Medical Association will be held in London, beginning with the annual representative meeting, July 21. The annual general meeting will be held July 25, and the incoming president, Lord Dawson of Penn, will give his inaugural address, July 26. The scientific sessions will be held, July 27-29. The centenary dinner of the association will take place, July 28. There is to be a pilgrimage to Worcester on Sunday, July 24, to unveil memorials to Sir Charles Hastings, founder of the association (The Journal, Dec. 5, 1931, p. 1718). Dr. William George Willoughby, Eastbourne, is the present president.

Dawson Williams Prize to Sir Robert Jones.—The second award of the Dawson Williams Memorial Prize will be made to Sir Robert Jones in recognition of his work in pediatrics in relation to orthopedics. With the consent of the council of the British Medical Association, the presentation will be made by the president of the association on the occasion of his address at the annual meeting in London, July 26. The prize was established in 1928 by friends of the late Dawson Williams, editor of the *British Medical Journal*. It is awarded every two years or at longer intervals, at the discretion of the trustees, for work done in pediatrics.

Medical Associations in China Merge.—Plans for the merging of the National Medical Association of China and the China Medical Association were announced in the *Chinese Medical Journal* for January. Before the Japanese invasion of Shanghai, it was planned to hold a joint conference in Shanghai, April 6-13, to effect the amalgamation. The China Medical Association, which was formerly the China Medical Missionary Association, was founded in 1886 and confined its activities principally to American and European medical missionaries. The National Medical Association, on the other hand, was founded in 1915 by Chinese practitioners trained in western medical colleges. The new association will be known as the Chinese Medical Association, and its official organ will be the *Chinese Medical Journal*, which is a recent combination of the former *China Medical Journal* and the *National Medical Journal of China*.

Deaths in Other Countries

Gregorio Mendizabal, known as the dean of Mexican physicians, died, February 19, in Mexico City, aged 86. Dr. Mendizabal made special studies of influenza and yellow fever. He had represented Mexico at various Pan American and international medical and public health meetings in the United States and Europe.

CORRECTION

"Remote Results in Treatment of Gastroduodenal Ulcers."—Dr. Jean-Charles Roux, editor in chief of the *Archives des maladies de l'appareil digestif et des maladies de la nutrition*, writes that the research on gastroduodenal ulcer, described in the Paris letter in The Journal, January 23, page 330, was initiated by the Society of Gastro-Enterology of Paris and that the complete reports are to be found in the periodical which he edits.

Feb. 6, 1932.

The Descent of the Testis

Continuing his lectures at the Royal College of Surgeons, Sir Arthur Keith said that embryology had entered on a new era. Eighty years ago Owen taught that nature, in fashioning the animal body, worked to plan, much as a builder obeys an architect's specifications. Then came Darwin, who showed that every embryo was its own architect—that the powers which shaped the unfolding embryo were resident in its developing tissues. But while accepting Darwin's teaching, embryologists still tried to explain developmental events as the result of mechanical happenings—of foldings and bendings. Only recently had they escaped from this, when it was discovered that parts of a living embryo could be detached and maintained alive and that certain parts contained growth-controlling substances by which they can compel neighboring tissues to cooperate in producing a new and completed structure. Scarcely a surgical operation had not its parallel in the early stages of development. Extensive plastic operations were carried out, parts were shifted, altered in shape or entirely removed. In all these operations the tissues themselves played the part of surgeon, and there were occasional failures.

One of the commonest developmental devices was the production of pockets or hernias. A hernia is produced in the later months in each groin of a human fetus. The extrusion of the testis is, from an evolutionary point of view, a late event, and it occurs in most mammals. In some it descends only in the rutting season and returns to the abdomen after it. In lower vertebrates (birds, reptiles) it remains permanently within the abdomen. We are still uncertain as to the reason for the genital exodus. If it does not occur, the testis rarely becomes perfectly functional and usually atrophies. The evidence of comparative anatomy suggests that the atrophy is due to the high abdominal pressures to which it is exposed during efforts, rather than, as has been suggested, the higher temperature within the abdomen.

How is this developmental hernia produced? John Hunter's description, though written more than a century and a half ago, is still the best. In the fourth month a fold of peritoneum passes from the lower end of the testis to the groin. The tissue within it begins to grow, forming a peritoneum-covered plug. The lower end expands into a process, like the finger of a glove. The tip grows against the body wall and the tissues recede and expand in front of it. The growing plug and peritoneal process bring about growth changes in all the tissues of the body wall and a tunnel is fashioned. To permit the testis to follow the advancing gubernaculum or growth plug, its vessels and duct elongate. When this coordinated growth movement is over, the peritoneum and subperitoneal tissues surrounding the point of exit immediately repair and close the opening. John Hunter not only recognized the anatomic means by which the migration of the testis was brought about but was two centuries ahead of the world in understanding its nature. He attributed failure of descent to "an imperfection of constitution" of the testis. In the light of modern knowledge, this can be translated into "imperfection of the growth-controlling mechanism" that brings about the descent.

Increase in Tar in London's Atmosphere

The report on atmospheric pollution for the year ended March, 1931, which has just been issued, shows that in industrial districts the amount of solid matter deposited or brought down by rain varied from 550 tons to the square mile at one point in Lancashire to just over 72 tons at Leicester. The average is between 200 and 300 tons a square mile. A reduction of the total deposit is recorded at about two thirds of the ninety-eight observing stations in forty-two important towns and cities. The most remarkable improvement is in the deposit of sulphates, recorded by thirty-five stations. This result is the more satisfactory as sulphur in the atmosphere plays a considerable part in the damage to buildings by smoke. Unfortunately, this improvement does not apply to London, where an excessive increase, amounting at one district in the west to nearly thrice the previous average, is recorded. In the city of London the tar deposit has increased nearly three and one-half times. No definite explanation is given for these increases. It seems that London will have to put up with black fogs for some years to come. Sufficient smoke is emitted during two or three hours of a winter's morning to provide the blackest fog, provided it fails to be carried away. There does not appear to have been any material reduction in atmospheric pollution during the last ten years, though conditions are better than in the days of the "pea-soup" fogs of thirty years ago, when gas fires were less used and railways were not electrified. The amount of smoke haze in London appears to be far worse than in some industrial districts.

Australian Natives Cannot Survive Contact with White Men

The University of Adelaide has in the past few years organized expeditions to study the Australian native, who is threatened with the fate of his kinsman of Tasmania—extinction. Much of the expense of the expedition has been provided by the Rockefeller Foundation. The last expedition was to central Australia and comprised leading Australian anthropologists —Prof. J. B. Cleland (chairman of the Board of Anthropological Research), Prof. T. H. Johnston, Prof. C. S. Hicks, Prof. H. J. Wilkinson and several physicians. The expedition makes the remarkable recommendation that those natives who have not yet come in contact with civilization should be prevented from doing so. They should be allotted extensive hunting grounds, on which Europeans should not be allowed under any pretext. The expedition considers that we surely owe this concession to a people from whom, by force and without any compensation, we have taken away their land and deprived, in too many instances, of the means of obtaining food in their own way, and even water. The expedition is afraid that those natives who have come under European influence, whatever care is taken of them, are doomed to early extinction. They have mostly lost interest in their old native customs and live a half-starved existence on the outskirts of civilization. They are made use of to some extent by the white man, but the responsibility of treating them as what they are—grown-up children—is not sufficiently recognized. Some come under the influence of undesirable whites, and the women too often produce half-castes. Thanks to the influence of Mr. Kramer of the Aboriginies' Friends Association, the natives were friendly to the expedition and submitted without difficulty to all sorts of examinations, such as blood testing, use of the apparatus for basal metabolism, and taking plaster casts of the face. The impression was received that they preserved a high standard of morals, according to their own standards. The marriages took place according to their code. But one result was that old men had several young wives, while young men had to content themselves with cast-off old wives or widows. This system has the advantage that when a man is getting too old to hunt and readily provide himself with food his wives can do this. On the other hand, the young man can provide food for his elderly wife.

The Birth Control Question

The continued pronouncements of Justice McCardie on birth control have aroused much criticism. Addressing a woman prisoner, he said: "You have pleaded guilty to the offense of abortion, performed at the request of a girl of 19. I think these abortion cases will continue so long as the knowledge of birth control is withheld. In my view the law of abortion should be amended; at present it does more harm than good. There are 300,000 mentally defective women, only a small part of whom are under institutional care. They are breeding freely every day with terrible consequences. In my view, miscarriage in such cases should be made compulsory. Too many men released from lunatic asylums go home and make their wives pregnant. The birth of such children should not be allowed. The time has come when the nation should be warned. I warn it today." He bound the woman over for three years (to come up for judgment if called on).

In the *Catholic News* a number of clerical denunciations of the judge's view have been published, and an interview was printed with Dr. Alfred Cox, medical secretary of the British Medical Association, who said: "I think the judge is exaggerating when he says that it is almost inevitable that a mentally deficient woman would bear a mentally deficient child. The legalizing of abortion opens up extremely grave questions. The British Medical Association has always taken the line that the teaching of birth control is not only a medical one but a question for the community, involving morals and religion, and the only way in which physicians can be said to have more weight than any one else is on the effects of certain methods of birth control or the induction of abortion from a medical point of view."

The lower house of the convocation of York of the Church of England has condemned the increasing dissemination through the post of literature and advertisements dealing with contraceptives and the growing display of these articles in shop windows. A resolution was unanimously passed that the postmaster general and the government should be pressed to restrict or prevent such advertisements and display. It was complained that the publicity given to the resolution on birth control of the Lambeth conference had caused an increase in the advertisement and display of contraceptives. The reply of the postoffice to representations on the subject was that nothing could be done to prevent circulars passing through the post, because the sale of contraceptives was not illegal in England. It was said that a tremendous encouragement had been given to immorality among the unmarried.

Raw Milk as a Preventive of Dental Caries

In the Section of Odontology of the Royal Society of Medicine, Mr. E. C. Sprawson, lecturer on dental surgery, London Hospital, reported observations to show that raw milk influenced the calcification of the teeth and conferred immunity to caries. He supervised groups of children in institutions and was impressed by the high incidence of dental caries among them. The incidence was progressively less in the teeth, whether deciduous or permanent, in the order of their eruption. He investigated the effect of a daily ration of raw milk begun during the first twelve months of life. As the deciduous dentition was not completed until the end of the second year, he excluded from the survey all the children thus fed, until they had reached the age of 2 years. The cases fulfilling this condition numbered only forty, but the results were remarkable. The average age at which the ration was begun was 4½ months, and when the children were observed at the age of 4 years not a trace of caries was found. In thirty-three other children who were over 12 months when the ration was begun (in none not later than 2½ years), twenty-six at the age of 4½ years showed no caries and the remaining seven had fourteen carious teeth. He had thus had the remarkable experience of examining seventy children over 2 years of age, of whom sixty-three were totally free from dental caries. Yet nearly all these children were subnormal on admission to the institution, suffering from gastrointestinal disturbances and rickets. When the ration of raw milk was begun at later ages, an effect was still evident. In twenty-eight children it was begun at the average age of 4 years and 8 months. The present ages of these children was from 7 to 10 years and 9 months. Though most of them had carious deciduous teeth, in only two was there caries of the permanent teeth. A further control was done at a still later age. Forty-four boys came on the ration before the end of the eleventh year and were now 13½ years of age. The second permanent molar was studied and eleven cavities were found in six boys. Raw milk appeared to confer incomplete immunity if begun at a time when it was no longer a physiologic food. Nearly all children got a milk ration during the first three or four years of life, but always sterilized by boiling or pasteurization. This destroyed or impaired the antiscorbutic vitamin. The effects of raw milk on the teeth indicated a longer period of breast feeding than usually practiced. For ideal dental development he recommended a daily ration of raw milk until the age of 14.

The Certification of Blindness

In 1930 the Union of Counties Association for the Blind appointed a committee of ophthalmic surgeons and others to report on the prevention of blindness. The committee found itself faced with the lack of any scientific data as to the prevalence and causes of blindness. It seemed to them that ophthalmologists when certifying blindness should at the same time record the defects ascertained on examination and the underlying causes of blindness. The ascertainment of blindness has become more important since the blind persons act was passed in 1920, granting pensions to all persons over 50 "so blind as to be unable to perform any work for which eyesight is essential." But the absence of any uniform method of certifying blindness raises doubts as to the correctness of some of the certifications. The committee recommends that no one should be registered as blind until he has been examined and certified by a practitioner with special experience in ophthalmology and that a common form of certificate be used in all cases. The information so obtained should be collected and studied. The committee is also impressed with the necessity of obtaining precise information concerning all cases of serious visual defect in children up to the age of 16, and for them it is recommended that a similar procedure should be adopted by the board of education. With regard to the form of certificate, one used in Scotland in which a distinction is drawn between the ascertained condition of each eye and the cause of such condition is recommended. The failure to make this distinction has led to some confusion in defining the causes of blindness. For example, in interstitial keratitis, the primary cause of the blindness is not this lesion but syphilis.

The Definition of Blindness

Following a recommendation of the ophthalmologic section of the Royal Society of Medicine, the ministry of health issued a circular giving a visual acuity of 3/60 as a limit under which a person may usually be considered blind, while 6/60 or better cannot be considered blind unless there are other visual disabilities, especially a much contracted field. But it seems that, in some parts of England, persons with visual acuity (after the correction of refractive errors) of 6/60 are considered blind and others with more than 6/60, if there are other visual defects. The committee makes the following recommendations. Visual acuity means the best direct vision obtainable with each eye separately or both together as tested by Snellen's types, with focus corrected. In general a person with visual acuity below 3/60 may be regarded as blind. In many cases, however, it is advisable to test the vision at 1 meter and not to regard persons having acuity of 1/18 as prima facie blind, unless there is also considerable restriction of the visual field. A person with visual acuity of 6/60, or better, may be regarded as blind if the visual field is markedly contracted in the greater part of its extent, and particularly if the contraction is in the lower part of the field. Persons in this group suffering from homonymous or bitemporal hemianopia retaining central visual acuity of 6/18, or better, are not to be regarded as blind. With regard to intermediate degrees of visual acuity (more than 3/60 but less than 6/60), such persons may be regarded as blind if the field is considerably contracted, but not if the visual defect is of long standing and unaccompanied by material contraction of the field; e. g., in cases of congenital nystagmus, albinism or myopia. The report has been addressed to the minister of health, who has it under consideration.

The Lowest Birth Rate on Record

The fall in the birth rate continues and the lowest rate on record is once more reported. The rate for England and Wales in 1931 was 15.8 per thousand of population, which is 0.5 below the previous lowest, recorded in 1929 and 1930. The death rate was 12.3 per thousand, which is 0.9 above that for 1930. The infant death rate was 66 per thousand live births, which is 6 above that for 1930, but only in 1928 and 1930 has this rate been lower. The death rate and birth rate draw closer together each year, so that a stationary population in a few years is in sight.

BERLIN

(From Our Regular Correspondent)

Jan. 25, 1932.

Election to the Berlin Chamber of Physicians

Berlin, by exception, has its own *ärztekammer,* or chamber of physicians, although otherwise there is only one chamber of physicians in each German state. The chamber of physicians is not a federal institution but is established in accordance with the laws of the individual states composing the *reich;* for example, the chamber of physicians for Prussia and the Berlin chamber of physicians were established by an act of the Prussian legislature, Dec. 30, 1926.

The chamber of physicians was primarily created to establish a body of physicians to consider all matters pertaining to the practice of medicine, and to preserve the public health, as well as to protect the interests of the medical profession. The state and communal authorities are under obligations to afford the chamber of physicians an opportunity to express their opinions on questions coming within their sphere. In the consideration of such questions, particularly if they concern public health administration, it is incumbent on them, in suitable cases, to consult such medical experts as may be recommended to them by the chambers of physicians. The chambers of physicians are empowered to establish welfare arrangements for the benefit of physicians and their dependents.

The members of the chambers of physicians are chosen by the physicians of the respective German states *(länder)* by secret ballot. All physicians in good standing may vote. The right is, however, held in abeyance pending the rendering of a judicial decision in the event that a court investigation involving a physician has been instituted. Elections are held every four years. The members of the chambers of physicians serve without compensation. The funds for carrying on the work of the chambers are supplied in the form of annual contributions from the electorate. During the present financial stringency, any surplus funds in the hands of the chambers of physicians are used chiefly for the support of aged physicians and physicians' dependents. Under present economic conditions, public health questions play an important rôle. Every physician who is practicing medicine, or is serving in a medical capacity, must report the fact to the board of directors of the chamber of physicians. The order of business, the duties of the chairman and of the board of directors, the form of voting, and other like matters, are prescribed in the enacted law. The state supervision of the chambers of physicians and their boards of directors is entrusted to the *oberpräsident* of the province, or state. The *oberpräsident* or his representative is empowered to sit in at the sessions of the chamber of physicians and to participate in the deliberations if he so desires.

The Aerztekammer-Ausschuss is a committee composed of delegates from the chambers of physicians of the various German states. It mediates, on the one hand, between the ministry of public welfare and the chambers of physicians, and, on the other hand, between the chambers of physicians themselves. The general supervision of the Aerztekammer-Ausschuss lies in the hands of the minister of public welfare. The medical courts of honor are governed by a special law.

Under normal conditions, an election of members to fill vacancies in the chamber of physicians proceeds quietly, but the present stormy political situation is beginning to influence fields in which pure reason should hold sway. The election to the chamber of physicians is regarded as an index to the attitude toward professional questions; hence the results of the recent Berlin election were awaited with great interest. No less than nine parties presented lists of candidates, and there was evidence that machine politics played some part in the results. A total of 5,026 votes were cast out of a total of 6,031 persons entitled to vote. The most votes (2,809) were cast for the candidates of the coalitionists, who stood for the preservation of a free medical profession. The next largest number of votes (685) were cast for the candidates of the Bund der Heilberufe für soziale Erneuerung (which comprises, among others, the physicians of the national socialists). According to the results of the voting, the mandatory distribution of members will be as follows: coalitionist list, 69; Bund der Heilberufe für soziale Erneuerung, 17; Jungärzte, 10; assistants, 7; trade-union physicians (communistic and sociodemocratic representatives of the trade-union idea in medicine), 6; social democrats, 5; ambulatorium physicians, 3; communists, 2, and the confidential physicians of the occupational brotherhoods, 1. A total of 120 members will be seated in the new chamber of physicians, which convenes early in 1932 and will be drawn from the nine parties as indicated. There are some physicians in Berlin who regard all this as undue imitation, on the part of physicians, of parliamentary tactics.

Pergamum and Ancient Medicine

Prof. Dr. Theodor Wiegand, the archeologist, spoke recently on "Pergamum and Ancient Medicine," before the Berliner medizinische Gesellschaft. Ancient medicine was highly developed, especially Greek medicine. Greek physicians occupied a high social position. Rational and empiric medicine, on the one hand, and medical magic were, at that time, more or less interwoven and not separated as they are today. The practice of medicine was regarded as a sacred task, being closely associated with the worship of the deity Asclepius, the god who came originally from Thrace to Greece, who is generally pictured with an attendant serpent, and who at a later epoch was represented in human form with the serpent emblem. The chief seat of this cult was located, during the period of the Roman emperors, in the city of Pergamum, where Galen, the most eminent physician of late antiquity, was a teacher, and where Wiegand, in recent years, has excavated the ruins of the great Asclepian temple and has reconstructed a picture of the buildings as they looked in ancient times.

Pergamum was famous for its excellent hygienic arrangements. The citadel, built on a hill having an altitude of 1,000 feet, was supplied with water by means of a system that collected the supply from a spring located on the mountain top, at an altitude of 6,500 feet, a wonderful feat of hydraulic engineering. This aqueduct was not constructed in the usual Roman manner but consisted of a pressure system that utilized the principle of communicating pipes, a knowledge of which was not supposed to extend back to that period of history. The excavators unearthed a pipe line the tile of which fitted together with great precision, the joints being tightly sealed with large hollowed-out stones. Even a purification chamber constructed on modern principles was discovered in the course of the system. The lower city was supplied with drinking water by means of the ordinary Roman aqueducts. The drinking water, in closed tile, lead or bronze pipes, was kept strictly separated from the open water canals of the streets. Severe penalties were imposed on persons found guilty of contaminating public wells. Even the cisterns in the private homes were officially inspected every year. There were also regulations concerning the protection of house walls against moisture. Large warehouses with specially ventilated hollow floors served for the preservation of food products.

It was not known until recently exactly where the sanctuary of Asclepius was located. It was accidentally discovered when the Turkish government erected in its vicinity a garrison for troops and used for building purposes some of the stones dug up out of the ruins. There were found, in this connection, certain stones with inscriptions that clearly revealed the nature of the ruined building. From the entrance of the large sanctuary a covered colonnade, a kilometer in length, extended to the temple proper. The excavations unearthed a large court of honor and a number of buildings, some of which were used as places of worship and some for therapeutic purposes. Chief reliance for cures was placed in the famous spring, which was rediscovered and which furnishes in truth a water of excellent quality. The chief therapeutic remedy employed by the followers of Asclepius was the so-called incubation, or the rite of sleeping in the temple. This seems to have been merely a modified form of suggestion treatment. Having fallen asleep in the temple, the patient had a dream in which the way to healing was pointed out to him. It is possible that a purposeful interpretation of the dream by the physician-priest played an important part. Through the inscriptions on the stones, much has been learned concerning the nature of their physical therapy. This consisted chiefly of dietetic and, in part, drastic water treatments and hardening procedures, which today occasion no little surprise and cause one to wonder that the patients were not injured by them. It must be remembered that they were frequently applied to obese persons and persons who had been injured by overeating.

For the diversion and recreation of the large group of patients who sought this ancient shrine, rows of Ionic marble columns extended for a distance of about 350 meters on the south, west and north sides of the open court, and on the north side stood a magnificent theater that seated 6,000 persons. This immense pile of buildings was erected during the period 140-180 A. D., during the reign of the Roman emperor Antonius Pius. Later, Emperor Septimius Severus resided in the temple, where his son Caracalla sought to be cured of a stubborn malady. A colossal head of Emperor Caracalla was unearthed by the excavations.

It is to be hoped that Wiegand will succeed this year, with the aid of funds furnished by the German-American Gustav Oberländer, in clearing away the débris from the whole court of honor.

A Diet for Sportsmen

Concerning the proper diet for the sport devotee there are as yet no generally accepted criteria. Rubner, a master of research on nutrition, states that an adult man weighing 70 Kg. (154 pounds), who, in addition to his occupational work, engages in reasonable physical exercises, requires daily about 3,200 calories. Other investigators on nutrition place the food requirement at from 2,100 to 4,000 calories. As especially suitable for the sport devotee the following menu has been prepared: for breakfast, a large cup of coffee with a liberal amount of hot milk or other beverage; two slices of bread, with butter or marmalade; at noon, from 100 to 150 Gm. of meat, five or six potatoes, a vegetable or salad, fruit; at night, three slices of bread with cold meat, fruit. Pickert in Hamburg has undertaken to study this question on a large group of men whose working performance and nutrition could be accurately regulated and observed. He used a group of policemen in training and reached the following results: The group of twenty-four men averaging 26 years of age, during a thirty-two days' course of full training, received about 4,300 calories, about 2,300 calories of which were used up in basal metabolism, food action and energy exchange. It was found that a mixed diet with regular side-dishes of fresh vegetables, salads and the like is the most satisfactory. That these quantities of food are amply sufficient was shown by the gain in weight, by a gradual increase in performance over a long period of time, and by the excellent health conditions prevailing in the group.

The Seventieth Birthday of Prof. Heinrich Braun

Every discovery has its origin in a skeptical trait of character, the ability to imagine and a clear observation of realities. Without the skeptical attitude, the power of observation is impaired by the events of the past, and without the ability to imagine the passion for creating is absent. Whereas, in the Romanic type, these three characteristics are immediately apparent from the quickness of the reactions, in the classical type everything is concealed and suppressed. Braun's creative activity developed in the quietness of the laboratory. Whereas the discoveries of Schleich that were destined to miscarry became at once generally known, the things that are fundamental in local anesthesia, the determination of the value of local anesthetics by the self-trial with the Corning (not the Schleich) wheal, have not become common property to this day; that, secondly, his fundamental discovery (1900), the mixture of narcotizing and angiospastic substances, which made local anesthesia, for the first time, a reliable and harmless procedure, received little attention, and that essentially only the third part of his researches, the painstaking development and description of the method, received deserved recognition. In other words, with the aid of the wheal experiment and with the addition of epinephrine, any one who possessed sufficient anatomic knowledge could now practice local anesthesia. Only the details needed to be worked out. With these words that Kulenkampff, Braun's successor, uttered in his address delivered in honor of the seventieth birthday of his former teacher, more was characterized than the mere external fact of the completion of seventy years of existence. These words served to portray a personality that achieved world fame through the aforementioned performances, which speak for themselves, and which, with the simple beginning in a provincial hospital in Zwickau, Saxony, became known to the physicians of all countries. Such a performance presupposes the unremitting application of all the qualities of the man, who, with conscious endeavor, took the words of Billroth as a guide and sought to make himself dispensable by aiding in the training of self-reliant physicians. Braun's autobiography contains a classic formulation of this thought, the application of which extends far beyond its purely medical aspects and which is wholely characteristic of the writer: "The social life and the social relations of man presuppose constant compromises, if they are to have a definite purpose and are to meet with any success. One may often be compelled to accept for the time being the idiosyncrasies and the peculiar views of one's associates; one may have to adjust himself to them or even to make use of them. In practical life, one must not cling to ideals that can never be realized. The person who holds out for an ideal condition before taking any action will therefore never be able to create anything permanent. Harmony can be secured only when men strive to attain an optimum that is limited and determined by the given conditions. That is nature's law that must be observed and fulfilled."

Congress of Urology

The tenth Congresso della società italiana di urologia was held at Bari under the chairmanship of Professor Bruni. Professor Righetti, director of the Clinica chirurgica, in the opening address, referred to the close ties that unite urology to surgery, from which it sprang. One cannot become a urologist without first having been a surgeon. This principle, which should be kept in mind by those who plan to devote themselves to urology, originated with the ancient Italian masters of surgery, to mention only Mariano Santo da Barletta, whose instrument for the extraction of calculi from the bladder will be recalled.

DISEASES OF THE NECK OF THE BLADDER

The first topic on the program, "Diseases of the Neck of the Bladder, Excluding Hypertrophy and Cancer of the Prostate," was presented by Professor Alesio of Turin and Professor Pisani of Milan. Professor Alesio pointed out that the interest of urologists has been particularly directed to the study of those dysuric manifestations that are caused by a lesion of the neck of the bladder. Although clinical observation has brought to light many cases, the etiology and the pathogenesis are not well established. It is customary to apply the term "neck of the bladder" to the lower part of the bladder but it is difficult to specify morphologically the limits and the extent of the collum. Following the details of the histologic structure along the vesico-urethral tract, one distinguishes at a certain point two diverse structural planes. As regards the muscular tunic, from the surgical point of view, the neck of the bladder is no better defined. Beyond the internal urethral orifice, a vesical bend and a urethral bend of the collum will be observed, together with other connected structures: the uvula vesicae, the prostatic sinus, and the upper extremity of the urethral crest. The site, the direction and the mobility of the neck of the bladder demonstrate its topographic importance, and its backward and downward movement reveal this importance when the bladder begins to empty itself, as shown by the fluoroscopic study of the process of micturition. Connected with the prostate, as it is, the neck of the bladder derives to a great extent its structural characteristic from the glands of the prostate, scattered in every direction through the muscular and connective tissue of which it is composed. In the glandular element one must recognize an important component of the neck of the bladder, which being diversely constituted in different subjects serves to mark the individual character.

Regarding the contractility of the collum and the mechanism of the opening and closing of the bladder, it has been assumed for a long time that the motor fibers that innervate the collum, being derived from two different systems, the sympathetic and the autonomic, have an antagonistic action. But, according to modern conceptions, this antagonism is by no means demonstrated, and the fact must be recognized that uncertainty still exists in regard to the inhibitive action of the nerves of the bladder. New difficulties arise when one seeks to demonstrate the existence of a spinal center by the tonic contraction of the sphincter. The existence of such a center would seem to be established by data based on clinical observations and not contestable by the assumption of an automatic function developed in the parietal nerve elements; but it is difficult to localize it. The neck of the bladder is subject to functional disturbances, which are caused chiefly by mechanical influences, which are brought to bear when there occur changes in form in the lower part of the bladder and in the portion of the urethra capable of preventing the closure of the bladder or of constituting an obstruction at the internal urethral orifice. The obstruction may be complete or incomplete, temporary or permanent.

Calculi and foreign bodies are the most common factors that obstruct the closure of the bladder; in addition there occur tumors, cicatricial adhesions, and sclerotic changes of cervical tissues. Among the factors causing complete temporary obstruction, is congestion. Stenosis, valves, hypertrophy of the verumontanum, tumors or cysts may impair the permeability of the urethral lumen. The terms "valves," or "bars," of the collum, "median bars," "prostatic bars," stenosis, contractures, by means of which an effort is made to bring under a single category most of the abnormalities of the collum and those lesions that cannot be classified under the neoplasms, have no ground for existence if considered histologically. Nevertheless, it is necessary to admit that there are peculiar diseases of the neck of the bladder although pathology has not created a special chapter for them. The causes of these diseases may be nervous or organic. Inflammation constitutes the more common etiologic factor in diseases of the neck of the bladder, the most typical manifestations of which are inflammatory sclerosis and constrictions.

Prof. Luigi Pisani of the University of Milan presented the second part of the topic, which dealt with diseases of the neck of the bladder from the clinical point of view. He said that it is impossible to separate in a frank manner the pathology of the neck of the uterus from that of the prostate, the pathology of the seminal vessels and that of the posterior urethra in the man, and of the urethra and of the reproductive organs in the woman, from the pathology of the bladder. The topic should take as its principal subject the retentions of cervical origin, due mainly to a lesion localized in the collum, which impairs its function and causes the retention; hence his study would consider chiefly the collum in the male sex. Characteristic of these types is the rarity of precise observations, which explains the manifold terms proposed by various authors. For the term *prostatici senza prostata,* proposed by Guyon, have been substituted the terms vesical prostatism, contractures, fibrosis, atrophy of the prostate, spasm, idiopathic hypertonia of the smooth sphincter muscle, congenital dyscrasic hypertrophy, and others. There are many theories, and it is important to attempt to clarify the question.

Vesical urinary retention always presents in its pathogenesis obscure features pertaining to the cervical lesions of the bladder. The purpose of this paper was to consider whether it is possible to assume the existence of a clinical entity whose pathologic basis, different from that of prostatic adenoma, has likewise its seat in the neck of the bladder, and whose symptomatology culminates in the manifestation of retention. This clinical entity has, in common with the other well known forms, the same complications; but the clinical and instrumental observations on which are based the diagnosis and the treatment are different.

It is difficult to confine attention to the collum and to the smooth sphincter muscle, and to neglect the two other factors that play a part during micturition: the vesical muscle and the striate muscle. The manifestations ascribed to the neck of the bladder are often symptoms of a disorder which has its focus at another point and which nearly always requires the participation of other pathologic causes not identifiable in the collum (detrusor urinae muscle, smooth sphincter muscle). Hence, clinically, it is difficult to speak of "diseases of the neck of the bladder" and make of them a special nosologic chapter. There may, however, be clinical syndromes in which the pathologic cause is strictly localized in the collum, is primarily in that seat, but is not influenced by other remote factors, so that a cure can be effected only by the removal of the collum. The clinical syndrome can be characterized by successive stages. In the beginning there appear, in the collum, minute structural lesions, which produce at the opening an abnormal state of resistance. There begins then the first phase characterized by manifestations of an irritative nature, with disturbance of micturition of a dysuric nature. There follows an extension of the structural lesions, which render the resistance at the opening more or less permanent. The collum undergoes an irregular thickening and a retrocervical, pretrigonal cavity is formed. After a period of apparent quiescence, there appear complications that commonly supervene as corollaries of every vesical retention, mainly sepsis, pyelo-uretherectasis, backflow, urinary infection, and the like.

The interpretation of the functional disturbances is still somewhat uncertain. It does not appear that one may speak of a spasm, much less of a paralysis of the trigon. Some authors support the theory of an increased tonus of the sphincter muscle. The speaker considers it justifiable to classify among the important urinary syndromes, alongside prostatic adenoma and urethral stenosis, the rigid induration of the neck of the bladder, called by some authors "disease of the collum." He prefers to call this syndrome, in view of the definitive anatomic substratum, by the term "sclerosis of the collum." The fundamental nature of this type is degenerative. It is an acquired disease and has a chronic or toxic course. It is not easy to distinguish this condition from prostatic adenoma and atrophy of the prostate. For the diagnosis, in addition to the described symptoms, bimanual exploration, endoscopic examinations and cysto-urethrography are useful. The treatment should be influenced by the same conceptions as prostatic adenoma. In the beginning types medicinal remedies, bloodless instrumental treatment and electrotherapy are effective. The presence of a vesical residuum makes necessary direct operative local treatment. Of all the proposed methods the speaker prefers total removal of the collum, leaving the bladder wide open. This method has been followed by immediate good results.

Professor Cimino of Palermo, commenting on a series of cases, said that one must be careful in the use of roentgenotherapy in the treatment of these morbid types. Bloch of Florence stated that he did not agree with the speakers with regard to the pathogenic conception of "disease of the collum." Nego and Sacchi of Turin and Lilla of Leghorn contributed communications on "disease of the vesical collum." Columbino of Turin suggested the substitution of "wide stenosis of the collum" for the term "disease of the collum." Cilento of Naples discussed endometrioid formations of the bladder that sometimes simulate vesical retention.

After some further communications, the society chose Rome as the meeting place for the next congress. The chief topic on the program will be "The Remote Results, Orthopedic and Functional, of Renal Surgery and of Consecutive Urethral Surgery."

Professor Calmette's Standpoint on the Lübeck Affair

Professor Calmette publishes a note in a recent issue of the *Pesti Napló* in which he says: "It was my intention to cloak myself in deep silence up to the end of the Lübeck trial. As, however, the antituberculosis preventive inoculations were unjustly attacked in their foundations, particularly by Prof. Dr. Enderlein, in a German paper, I find it necessary to make known my standpoint. It is my feeling that I owe this, not so much to French medical science, the less so toward my own person, but toward such a scientific method, which interests all mankind. But let the figures speak for themselves. Up to Oct. 1, 1931, about one million children have been inoculated in the whole world, without a single such mishap or accident that could be attributed to the inoculations proper. In Lübeck, 242 children were inoculated and out of these 76 died as a result of the intervention. The conclusion to be drawn is that in Lübeck the children received something quite different from B C G. It is my opinion that it is the task of the Lübeck court to decide the nature of this vaccine and to verify the responsibility. This much I can say about the essence of the matter.

"Now let us discuss the article of Professor Enderlein, which appeared in the *Deutsche Allgemeine Zeitung.* I have to enlighten the readers who took notice about the contents of this article, that those so-called physiologic data, which are enumerated in the article, are nothing else but pure assumptions, abstract conclusions, which are not based on any experimental facts. The absolute lack of practical confirmation robs these facts of any scientific character. It is regrettable that from an occasion of such great importance some people try to influence the public by worthless arguments. In this error they are much less led by the love of justice than by an endeavor to gratify their passions. In the land of Pasteur, the opinion is prevalent that such excursions to the camp of politics have to be strictly avoided. Our task can be only to work for the advancement of science and particularly for the progress of preventive medical science. Instead of publishing much or often harmful theories we follow the plan that we publish only such reports that have been scrupulously controlled by experiments. This is our tradition and this is our strength. We can verify that, since the start of the B C G disputes, applications for vaccines have been made in an ever increasing number. At present we supply daily vaccinating material sufficient for 320-340 children; that is to say, the number of inoculations made in France in a single day exceeds the number of the total inoculations made in Lübeck. On the other hand, control experiments are in course all over the world and all of these prove favorable to B C G, the harmlessness of which is beyond doubt. Among such circumstances we await the opinion of the German government's experts, before the Lübeck court, with full confidence, and we hope that their opinions will be given the greatest publicity."

Strike of Seventy Young Physicians

Seventy assistant physicians and junior dressers, employed at the outdoor departments of the Budapest Jewish hospital, went on strike because the management of the hospital refused their appeal for salaries. The hospital board argued that, owing to unfortunate financial circumstances, they have to fight to keep the hospital going; on the other hand, the positions, when announced, were emphasized to be gratuitous. The medical association intervened on behalf of the young doctors, also in vain, because the managers of the Jewish hospital declared it was utterly impossible at present to grant their request, although they agree that it would be fair to allow some modest payment, which they will let them have whenever the financial conditions of the Jewish community improve. The assistant physicians did not resume work.

Nervous and Mental Indications for Induced Abortion

Dr. P. Büchler of Budapest University holds the view that induced abortion is indicated in cases of severe reactive depression, when the patient displays obstinate resistance against taking nourishment, or if she develops suicidal tendencies. Institutional treatment must first be tried, and abortion is indicated only if this treatment is not practicable. In an institute, resistance to food can be overcome by forcible feeding, and suicide can be prevented by careful watching; but even in institutions, the pregnancy may have to be terminated. Most difficult is the problem of schizophrenia. Although it is beyond dispute that the reproduction of schizophrenic individuals is undesirable, effort must be directed to the prevention of gestation rather than its interruption. There are no definite general indications in psychiatry, but in psychopathies arising from severe intoxications and infections, and in certain cases of paralysis, intervention is justified, and, at any rate, danger to the life of the mother can be avoided. As a rule, when a psychosis is suspected, Dr. Büchler recommends the conveyance of the patient to a psychopathic hospital, where the physician in charge can take what action he deems necessary. Severe cerebral and spinal diseases are absolute indications for abortion. Disseminated sclerosis is an important one, because this diagnosis tends to progress after childbirth: palsies, ataxia of a great degree, and the quick loss of strength may follow. This holds true also for locomotor ataxia since ataxia increases after childbirth, and bladder and intestinal troubles may supervene. It is beyond dispute that spinal and cerebral tumors, syringomyelia, progressive spinal muscular atrophies, hereditary chorea, lateral sclerosis, and severe forms of epidemic encephalitis form absolute indications. In doubtful cases, Dr. Büchler holds that social and eugenic considerations may be allowed to influence the decision, but only to a minor degree.

The Occupational Diseases of Physicians

Dr. Antal details in the *Népegészségügy* (People's Health) the results of his investigations as to the dangers to which physicians while following their vocations are exposed. He says that the public does not appreciate the risks to which physicians are exposed when they attend them. Behind the back of the doctor in the tropics there is constantly lurking the bugbear of bubonic plague, cholera and yellow fever. The Dutch government knows this well. This is why after a comparatively short term of service a full pension is allowed, few surviving to enjoy it. If a patient falls ill with an infectious fever on a ship, everybody shrinks from going near the cabin where the patient lies, but the surgeon has to rush to him, as if he had a magic mantle which protects him from all infections. How different it really is. Not only the physician himself but also his family and surrounding, intimate friends are endangered. How many doctors have carried the deadly scarlatina and diphtheria into their own families? How many children of physicians became the sacrifices of their father's occupation? Physicians employed in insane asylums are prone to special dangers. They are not infrequently attacked, cruelly beaten, and even killed by their own patients. Was not the unfortunate Dr. Gudden dragged into the water and drowned by the crazy Louis II, king of Bavaria? Doesn't blood poisoning, syphilis and tuberculosis occur frequently enough with surgeons, anatomists and pathologists? We all know the expression "dentist's heart," which is the consequence of the forward posture of the body through the years. Eye disease may be the result of constant microscopic work as is done by histologists and bacteriologists. The great Malpighi became almost totally blind from continuous microscopic work. How dangerous may be the work of the radiologist. Practitioners respond to requests for their services in the most severe weather. In many cases they contract sciatica, rheumatism, pneumonia as the result. We know from statistics that the relatively short duration of the lives of physicians is due to heart diseases and arteriosclerosis, the oncome of which is enhanced by their work.

JAPAN

(From Our Regular Correspondent)

Jan. 21, 1932.

Smallpox on Ships at Yokohama

A first-class passenger, an American, on board the steamship *President Jackson,* which entered the port of Yokohama with about 136 passengers, was found to have smallpox, January 3. After the examination of fifty-four persons among the passengers and crew, who came in contact with the disease, all persons on the ship were allowed to go ashore. Another case of smallpox was found on a British steamer of the United British Shipping Company, which left Shanghai, January 12, and touched at Yokohama on her way to Vancouver, January 15. The patient, the first mate of the ship, was sent to the hospital. The authorities are of the opinion that there is no danger of the disease spreading in Japan.

Health Problems in Tokyo

The metropolitan police held a meeting of health officers of all the police stations in Tokyo, January 11, to find out what epidemic diseases were present. From January 1 to January 6, 198 cases of infectious diseases were reported in Tokyo. The total number of cases of epidemic diseases that occurred during 1931 was 22,759, an increase of 2,098 cases over the number that occurred in 1930. The increase was due largely to diphtheria, scarlet fever and dysentery; the 4,782 cases of typhus represents a small decrease. The cases of dysentery in children seem to be on the increase in number this year.

The social bureau, which has twelve children's consultation offices in Tokyo, intends to examine the members of 12,000 families and to give them medical advice.

In Hongo, one of the fifteen wards of Tokyo, Baronesses Wakatsuki and Shidehara, wives, respectively, of the ex-premier and the ex-foreign minister, and other women of rank, plan to raise a large sum of money to improve the health of children whose parents are too poor to have them take their lunch to school. The committeemen of the thirty-six social work offices in the city will cooperate in this work.

Medical Establishments

The government dietetic institute, which was about to be discontinued for reasons of economy, it is reported, will continue as an independent establishment through the strenuous efforts of the director of the institute, Dr. Saeki.

Demonstration at Leprosarium

On the evening of January 17, about 480 of the 700 patients of the Kyushu Leprosarium tried to escape and go to the Kumamoto prefectural office to present a petition to the authorities. The demonstration was caused by a rumor that the chief of the asylum, Mr. Kawamura, and one other member, who were loved deeply by the patients, were going to be removed from their posts. Policemen, gendarmes and firemen succeeded in making them return to the institution.

The Medical Budget for 1932

Generally, the budget for the fiscal year 1932 has been curtailed in all departments in this country excepting that of public health. Especially the following six items can be said to have received generous appropriations: to aid in carrying out antiparasitic regulations, 10,000 yen; for the manufacture of morphine and allied alkaloids, 12,250 yen; for the enlargement of the national leprosarium, 70,000 yen; for the enlargement of the Kusatsu leprosarium, 120,000 yen; for the manufacture of codeine hydrochloride, 197,178 yen; for the International Congress on Hygiene, 5,000 yen.

Medical Meetings

The twelfth general meeting of the Keio Medical Society was held, Nov. 6, 1931, in the Keio Medical College at Yotsuya, Tokyo. Dr. Jennings, an exchange professor from the Rockefeller Foundation, was invited to lecture on the "Significance of Fetal Defects." Professor Koizumi acted as interpreter.

At the scientific meeting of the Kitasato Institute in Tokyo, Nov. 17, 1931, Dr. Matsunaga read a paper on "Hemolysis by the Staphylococcus." Dr. Mijajima, who was home on leave of absence from the League of Nations, made an address on the present condition of medical affairs in Europe and America.

Personals

Dr. Nozu of Tokyo Imperial University, Dr. Okuno of the Government Institute for Infectious Diseases, and Dr. Akatsuka of the St. Luke's International Hospital at Tsukiji, Tokyo, have left Yokohama for America, to study for two years at the Rockefeller Institute. After their return home they are to be rural health directors.

Marriages

John Austin Kerr, Santa Marta, Colombia, to Miss Janet Fraser MacLennan of Oberlin, Ohio, February 20.

Mark T. Phy, Hot Lake, Ore., to Mrs. Gladys R. Kidwell of Baker, at Walla Walla, Wash., Dec. 19, 1931.

Harry H. Epstein, Trenton, N. J., to Miss Ruth Goldstein of Brighton Beach, N. Y., February 21.

Arthur Taylor Henry, Vancouver, B. C., Canada, to Miss Marguerite Neilson, January 27.

John Braxton McKee, Winchester, Va., to Miss Ruth Loraine Bussey of Detroit, January 1.

Robert D. Evans, Minneapolis, to Miss Lucille Lusk of Mankato, Minn., recently.

Lewa Wilkes, La Grande, Ore., to Mr. Cecil V. Ager, Dec. 26, 1931.

Saul Freedman to Miss Belle Federman, both of New York, January 17.

Deaths

John Farquahar Fulton ⊕ St. Paul; University of Pennsylvania School of Medicine, Philadelphia, 1880; Secretary, Section on Ophthalmology, 1885-1886, Secretary, Section on Laryngology and Otology, 1893-1894, and Chairman, 1894-1895; Trustee American Medical Association, 1901-1904; professor emeritus of ophthalmology and otolaryngology, University of Minnesota Medical School, Minneapolis, member of the American Academy of Ophthalmology and Oto-Laryngology and fellow of the American College of Surgeons; past president of the Minnesota State Medical Association and the Ramsey County Medical Society; on the staffs of St. Luke's and Charles T. Miller hospitals; attending oculist to the Wilder Charity Dispensary; aged 73; died, February 1, of carcinoma of the bladder.

Norman Kitson McIvor, Winnipeg, Manit., Canada; Manitoba Medical College, Winnipeg, 1908; fellow of the American College of Surgeons; lecturer on surgery at his alma mater; served during the World War; surgeon to the outpatient department, Winnipeg General Hospital; aged 56; died, Dec. 30, 1931, in the Misericordia General Hospital.

Ernest Roy Logan, Omar, W. Va.; Ohio State University College of Medicine, Columbus, 1917; member of the West Virginia State Medical Association; served during the World War; aged 41; died, January 13, in the Hatfield-Lawson Hospital, Logan, of pneumonia, mitral stenosis and dilatation of the heart.

James Franklin McLay, Hamilton, Ont., Canada; University of Toronto Faculty of Medicine, 1913; served during the World War; formerly member of the board of education, medical health officer, coroner and member of the council of Grimsby; aged 48; was found dead in his garage, January 1.

Sidney Nixon Davis, Welland, Ont., Canada; Queen's University Faculty of Medicine, Kingston, 1891; member of the Associated Anesthetists of the United States and Canada; served during the World War; on the staff of the Welland County Hospital; aged 63; died, Dec. 31, 1931, of pneumonia.

Joe Albert Hartsell ⊕ Concord, N. C.; Jefferson Medical College of Philadelphia, 1912; past president and secretary of the Cabarrus County Medical Society; served during the World War; formerly county coroner; on the staff of the Concord Hospital; aged 42; died, February 18, of heart disease.

Clinton Benjamin Hawn ⊕ Albany, N. Y.; Albany Medical College, 1906; clinical professor of medicine at his alma mater; on the staffs of the Anthony N. Brady Maternity Hospital and the Albany Hospital; aged 50; died, February 12, of coronary thrombosis and coronary sclerosis.

William L. Baum ⊕ Chicago; Jefferson Medical College of Philadelphia, 1888; fellow of the American College of Surgeons; served during the World War; dermatologist to St. Luke's Hospital and the Post-Graduate Hospital; aged 64; died, February 22, of cerebral hemorrhage.

Ralph Spencer Cone ⊕ Westwood, N. J.; University and Bellevue Hospital Medical College, New York, 1906; for seventeen years member of the board of health; aged 52; died, January 24, of carcinoma of the stomach with metastasis to the mediastinum and neck.

Augustus Farlin House, Los Angeles; Cleveland Medical College, 1871; formerly associate professor of clinical surgery, Cleveland College of Physicians and Surgeons; Civil War veteran; aged 84; died, February 2, of coronary thrombosis and arteriosclerosis.

Joseph A. Murphy ⊕ Medical Director, Captain, U. S. Navy, San Diego, Calif.; Medico-Chirurgical College of Philadelphia, 1898; entered the Navy in 1900; aged 56; died, January 22, in the U. S. Naval Hospital, of cerebral hemorrhage.

Aelic Edward Ferguson, Austin, Ky.; University of Louisville School of Medicine, 1905; member of the Kentucky State Medical Association; aged 56; died, February 2, in the Community Hospital, Glasgow, of heart disease and pneumonia.

Preston Joseph Johnston ⊕ Kane, Pa.; Medical College of the State of South Carolina, Charleston, 1913; member of the South Carolina Medical Association; served during the World War; aged 40; died, February 15, of coronary embolism.

George Phillip Pipkin, Pueblo, Colo.; Medico-Chirurgical College of Kansas City, Mo., 1902; member of the Colorado State Medical Society; medical superintendent of the Corwin Hospital; aged 58; died, January 27, of pulmonary tuberculosis.

George Winters Lilly, Kansas City, Mo.; University Medical College of Kansas City, 1887; formerly on the staffs of St. Joseph's Hospital and St. Luke's Hospital; aged 66; died, Dec. 26, 1931, of atrophic gastric ulcer.

F. Parks Ogden, Louisville, Ky.; University of Louisville School of Medicine, 1902; member of the Kentucky State Medical Association; formerly member of the city council; aged 51; died, February 6, of heart disease.

Charles Sheridan Downes, San Francisco; College of Physicians and Surgeons of San Francisco, 1900; aged 68; died, Dec. 2, 1931, in St. Mary's Hospital, of lobar pneumonia, arteriosclerosis and diabetes mellitus.

Flavius E. Hartsell, Oakboro, N. C.; Baltimore Medical College, 1895; member of the Medical Society of the State of North Carolina; aged 62; died, February 14, in the Yadkin Hospital, Albemarle, of encephalitis.

Jacob S. Hicks, Allegany, N. Y.; Trinity Medical College, Toronto, Ont., Canada, 1891; member of the Medical Society of the State of New York; aged 63; died, February 8, in a hospital at Colborne, Ont., Canada.

Hugh Lytle Hough ⊕ Lancaster, S. C.; Birmingham (Ala.), Medical College, 1908; formerly health officer of Florence, Ala.; aged 53; died, February 6, of injuries received in an automobile accident.

James Mendenhall Dunlap, Ansonville, N. C.; University of the City of New York Medical Department, 1876; aged 81; died, February 14, in the Anson Sanatorium, Wadesboro, of cerebral hemorrhage.

Samuel S. Salisbury, Los Angeles; Hahnemann Medical College of Philadelphia, 1873; member of the California Medical Association; aged 84; died, February 1, of cerebral hemorrhage.

Domenico Jorio, Los Angeles; Royal University of Naples Faculty of Medicine and Surgery, Napoli, Italy, 1903; aged 56; died, Dec. 17, 1931, of coronary occlusion and coronary sclerosis.

Wesley Wright Pirt, Winnipeg, Manit., Canada; Manitoba Medical College, Winnipeg, 1909; served during the World War; aged 50; died suddenly, Dec. 17, 1931, of angina pectoris.

Adam Herney, San Diego, Calif.; Ensworth Medical College, St. Joseph, Mo., 1893; aged 61; died, Dec. 26, 1931, of arteriosclerosis, hypertension, hemiplegia and bronchopneumonia.

Gibbon William Carson, St. Louis; Missouri Medical College, St. Louis, 1878; member of the Missouri State Medical Association; aged 77; died, January 23, of heart disease.

Rupert Edward McKibbon, Seattle; University of Toronto Faculty of Medicine, Toronto, Ont., Canada, 1897; served during the World War; aged 57; died, Nov. 25, 1931.

James Elijah Goethe, Jacksonville, Fla.; Baltimore Medical College, 1892; member of the Florida Medical Association; aged 77; died, February 1, of cerebral hemorrhage.

Joshua A. Downs, Los Angeles; State University of Iowa College of Medicine, Iowa City, 1897; aged 62; died, Dec. 30, 1931, of organic heart disease and lobar pneumonia.

John Bertrand Woodworth, Cleveland; Homeopathic Hospital College, Cleveland, 1893; served during the World War; aged 61; died, January 1, of chronic nephritis.

Thomas Judson McPhee, Nanaimo, B. C., Canada; McGill University Faculty of Medicine, Montreal, Que., 1907; aged 51; died, Dec. 20, 1931, as the result of a fall.

Albert Chester Johnson, New York; Bellevue Hospital Medical College, New York, 1894; aged 50; died suddenly, January 30, of carcinoma and thrombosis.

Haven Day Skinner, Modesto, Calif.; Drake University College of Medicine, Des Moines, Iowa, 1904; aged 50; died, Dec. 27, 1931, of cirrhosis of the liver.

Claude C. Craighead, Athens, La.; Kentucky University Medical Department, Louisville, 1906; aged 56; was killed, January 24, in an automobile accident.

Clifford Samuel Chapin ⊕ Great Barrington, Mass.; Bellevue Hospital Medical College, New York, 1896; aged 58; died, January 27, of angina pectoris.

Frederick Alexander Rosebrugh, Grimsby, Ont., Canada; University of Toronto Faculty of Medicine, 1892; aged 63; died, Nov. 25, 1931, of pneumonia.

Robert Newton Mekemson, Biggsville, Ill.; College of Physicians and Surgeons, Keokuk, Iowa, 1882; aged 83; died, January 21, of mitral insufficiency.

Lorrimer Fauntleroy James ⊕ Richmond, Va.; Medical College of Virginia, Richmond, 1895; aged 57; died, Dec. 29, 1931, of influenza and pneumonia.

Robert Nathaniel Todd, Indianapolis; Central College of Physicians and Surgeons, Indianapolis, 1899; aged 59; died, January 27, of pernicious anemia.

Oliver Bernard Witte, Fredericksburg, Texas; University of Tennessee College of Medicine, Memphis, 1919; aged 38; died, January 14, of pneumonia.

Daniel Thomas Crawford, Youngstown, Alta., Canada; University of Toronto Faculty of Medicine, Toronto, Ont., 1896; died recently, in Hanna.

Guardey O. Hall, Oklahoma City; Epworth College of Medicine, Oklahoma City, 1909; aged 49; died, January 27, of acute dilatation of the heart.

Annie Laurie Sawyer ⊕ Atlanta, Ga.; Woman's Medical College of Pennsylvania, Philadelphia, 1900; aged 67; died, January 20, of myocarditis.

Arthur Charles White, Chickasha, Okla.; Toledo (Ohio) Medical College, 1897; aged 59; died, January 18, of chronic nephritis and endocarditis.

Albert Hans Scheffsky, St. Louis; St. Louis College of Physicians and Surgeons, 1918; aged 43; died, January 29, of illuminating gas poisoning.

Dennis D. Casto, Ripley, W. Va.; University of Louisville (Ky.) School of Medicine, 1891; aged 64; died, January 18, of carcinoma of the liver.

John B. Aycrigg, Ridgewood, N. J.; College of Physicians and Surgeons in the City of New York, 1879; aged 77; died, January 25, of pneumonia.

Charles W. Salisbury, Los Angeles; Starling Medical College, Columbus, 1882; aged 77; died, January 21, of chronic nephritis and cystitis.

Fred Leland Goddard, Goddard, Alaska; Long Island College Hospital, Brooklyn, 1887; aged 69; died, January 9, of cerebral hemorrhage.

Charles W. Judkins, Skowhegan, Maine; Hahnemann Medical College of Philadelphia, 1881; aged 76; died, January 22, of heart disease.

Elmer Martin Perry, Fort Spring, W. Va.; Baltimore Medical College, 1895; aged 62; died, January 6, of asthma and bronchopneumonia.

Howard C. Jones, Danville, Ind.; Indiana Medical College, Indianapolis, 1877; aged 78; died, January 23, at Knox, of pneumonia.

David R. Harris, New Castle, Pa.; Hahnemann Medical College of Philadelphia, 1878; aged 77; died, in January, of heart disease.

John W. Hall, Portland, Ind.; Medical College of Ohio, Cincinnati, 1872; aged 86; died, January 20, of cerebral hemorrhage.

Robert H. Casperson, Miami, Fla.; Jefferson Medical College of Philadelphia, 1884; aged 72; died, January 23, of myocarditis.

Hannibal A. Greenleaf, Clarksville, Ind. (licensed, Indiana, 1897); Civil War veteran; aged 85; died, January 15, of senility.

Abraham F. Smith, Urbana, Ind.; Columbus Medical College, 1878; aged 79; died, January 28, of embolism.

Martin V. Miller, Palatka, Fla.; Atlanta Medical College, 1893; aged 57; died, January 24, of pleurisy.

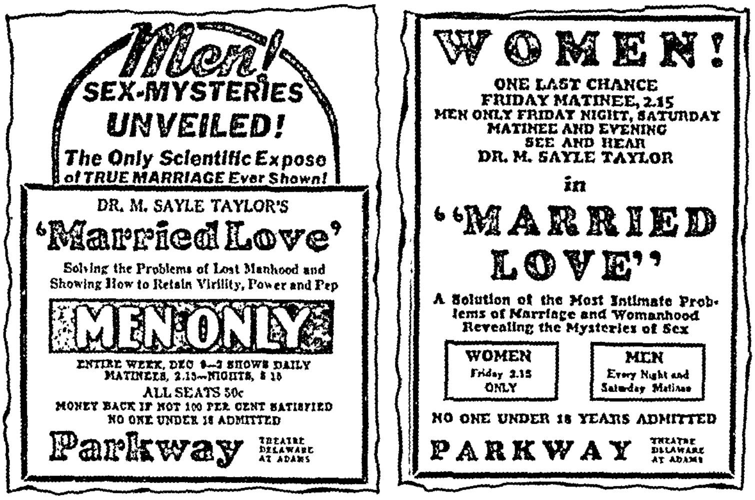
Bureau of Investigation

M. SAYLE TAYLOR

"America's Doctor of Matrimony" Who Claims to Reveal the Mysteries of Sex

"Dr." M. Sayle Taylor goes about the country discoursing on sex, selling books and pamphlets on the same subject and exploiting a "patent medicine" which seems to have been called, variously, "Vagitone" and, more recently, "La-Fon." Vagitone used to come as a liquid, but when the name was changed, it was put out in powder form. Taylor also sells a vaginal douching device that he calls "Vagispray." M. Sayle Taylor's present activities are of comparatively recent date. Some five or six years ago, Taylor is said to have been superintendent of schools in North Bend, Oregon. While in that city, he is said to have become associated with a Mr. and Mrs. Westheffer in leasing a hotel. After Mr. Westheffer's death M. Sayle Taylor left North Bend in 1926.

M. Sayle Taylor has appeared at motion-picture theaters in connection with films of an erotic character; at other times, he has given "stage presentations" in which were used "living models" and "human charts." Three or four years ago, Taylor was in Chicago appearing in connection with a motion picture entitled "Streets of Sorrow." The Chicago *Tribune's* motion-picture critic is a woman and because Taylor, at that time, was advertising that his show was for "Men Only," she asked one of the men on the staff of that paper to drop in and report what he found. Mr. Babcock, the reporter in question, gave what we believe to be the best description yet of Taylor's performance and it is revealing enough to be quoted at some length:



Men!
SEX-MYSTERIES

Photographic reproduction (greatly reduced) of some typical M. Sayle Taylor advertising.

"CHICAGO YOKELS READY VICTIMS OF ANCIENT 'MEN ONLY' STUFF"

> "The 'Men Only' show now running at the Rose theater is the choicest bit of boob bait to be found in the loop. It is the old outdoor medicine show, the street carnival 'anatomy' show, a 'Way Down East-Lulu Belle-Shanghai Gesture' production, and the old army game all wrapped up for the price of one. The loud speaker at the Rose screams to the passerby on Madison Street that here is a sensational exposé of sex. The passing sucker pauses, and bites. Inside, after separating himself from 50 cents for admission, he is inveigled into forking over a dollar for further 'information.' And this, mind you, in the heart of civilized, sophisticated Chicago. The performance purports to be the unreeling of a movie entitled 'Streets of Sorrow'—'and special features.' They consist of a news reel and a lengthy discourse by the self-styled sex evangelist of the world.
>
> "This Billy Sunday of the sex world says his name is Dr. M. Sayle Taylor and that his title is president of 'The National Society of Eugenics—strictly philanthropic.' His 'message' is so appallingly crude and nastily nauseating that at first the stronger stomached of the audience are inclined toward lusty laughter. However, they gradually succumb to the wizardry of his eloquence, until, at the end, they are whipped into a frenzy of morbid sensationalism. At that point comes the high powered salesmanship. Three paper pamphlets, dealing with the mating instinct and other problems appertaining thereto, are produced, and sold for a dollar a set. . . . 'The ushers will now pass among you, gents. Your first and last chance to get this startling information—and all for one little dollar bill.' . . . The ushers are usherettes of, apparently, immature years.
>
> "At first the doctor impressed me as a learned man become an introspective entomologist on the subject of sex. But when I saw the cash register developing a hotbox I concluded there might be laughter in his lunacy. The man of science explained that he had intended to demonstrate with graphic charts and beautiful pictures, but that the City Hall wouldn't permit it. I shudder to think what might have been unfolded before my eyes had not Mr. Bill Thompson and his minions stepped in and preserved my innocence.
>
> "As for 'Streets of Sorrow': The doctor took up so much time that I could stay for only the fore part of the movie. What I saw was a mawkish oversexed overdone, amateurish attempt to depict post-war Vienna. Noting that it featured Greta Garbo, I sought to learn the year of its vintage, but could find no date indicated. Acting, direction, plot, and photography were equally bad. At the point where I made my regretful departure the soulful-eyed Miss Garbo had just accepted extra money from her employer. What thereupon took place or happened to the poor working gel I can only surmise."

In June, 1930, Taylor was putting on his stuff in New Orleans and the papers, at that time, reported that M. Sayle Taylor had been arrested "on the charge of operating a disorderly house." The District Attorney reported that Taylor claimed at first to be a medical man, but this was found to be false, and that he also claimed to be well known in London; this, too, was found to be false. Taylor offered to close up and leave town and as the officials' object was to stop his so-called lectures, he was permitted to do so and the case was dismissed.

When Taylor was in New York in 1929, he was forced by the authorities to drop the title "Dr." before his name. There, apparently, he was working the "stage-presentation" scheme, for according to a report that appeared in the New York *Herald-Tribune* at the time: "At the close of his lecture, the fat, thin, tall, short and normal girls paraded on to the stage in bathing suits," as a *piece de resistance* for the "women-only" audience, Taylor announced, "If you will all just wait, you will see the perfect man." And, as the *Herald-Tribune* stated, "not a woman budged until 'Samsted' had finished his classical posing."

As has already been mentioned, Taylor has for sale a number of little pamphlets that bear such intriguing titles as: "Facts for Wives — Plain Truths About Marriage"; "The Secret of Youth and Charm: Plain Sex Truths for Women"; "Natural Birth Control and Predetermination of Sex"; "How to Know Your Affinity: A Study of Glands"; "Sex Vigor: How Retained; How Regained."

These little brochures (about four inches by six inches in size and from twelve to thirty-two pages) come in highly-colored paper covers and are listed at 50 cents each. They are poorly printed on cheap paper, and when produced in quantities, should not cost more than one cent apiece to turn out.

A study of some of these brings out the interesting fact that the pamphlet, "The Secret of Youth and Charm," which comes in a cream-colored cover, is identical, except for a few additional lines, with "Facts for Wives," which comes in an orange-colored cover. Various booklets repeat entire paragraphs.

Taylor also puts out a little more elaborate book, "The Male Motor," which when bound in cloth is listed at $1.50. It appears that the thing essentially is a treatise devoted to the puffing of a device called the "Thermalaid," a rectal dilator with a rheostat attachment, sold by the Electro Thermal Company of Steubenville, Ohio. Incidentally, the publisher's statement shows that the book is issued from Steubenville, Ohio.

As has already been stated, Taylor sells an alleged douche medicament which used to be called Vagitone, and under that name was put out by the Hygienic Orificial Company, which in its advertising matter sometimes gave its address as 361 West Superior Street, Chicago, and sometimes as 711 Sedgwick Street—two addresses for different entrances to the same building. A few weeks ago, a visit to 361 West Superior Street disclosed that the Hygienic Orificial Company was gone and, apparently, had left no forwarding address. It appears now that M. Sayle Taylor does business from 2029 North Halstead Street, Chicago, under the name La-Fon Laboratories, Inc., said to be successors to the Hygienic Orificial Company, Inc. Further, as has already been stated, the name of his product has been changed from Vagitone to La-Fon.

Recently, M. Sayle Taylor was working Virginia and a telegram was received from a gentleman in Lynchburg, asking for information on this person, who was scheduled for a week's "lectures" in that city. The information was sent and we now learn that Taylor was not permitted to put on his "show." It will be interesting to see just how long Taylor will be able to continue in his present field of endeavor.

Queries and Minor Notes

Anonymous Communications and queries on postal cards will not be noticed. Every letter must contain the writer's name and address, but these will be omitted, on request.

CARDIAC MANIFESTATIONS IN SYPHILIS

To the Editor:—A white man, aged 41, a painter, well developed and nourished, and apparently in excellent health, came to me, Nov. 23, 1931, because of a skin condition over the region of the right temple. This was attributed to a scratch from a barber's comb received about a year ago. Shortly after, a purplish rash developed on the left forearm and persisted. The lesions did not cause symptoms, but because they did not disappear I was consulted. Other than the fact that the patient indulges moderately in beer and alcoholic beverages, and is an inveterate tobacco chewer, the history is entirely irrelevant. Examination revealed an indurated papular lesion over the right temple extending on to the pinna of the ear, and a tuberoserpiginous lesion on the left forearm and on the right nates. An enlarged left epitrochlear gland was palpable, but no other abnormalities were noted. The heart was regular, with a rate of 80 beats a minute; the blood pressure was 128 systolic and 80 diastolic; no murmurs or other adventitious sounds were heard. While there were no viscereal signs evident, a presumptive diagnosis of a tertiary syphilid was made. A Wassermann reaction ascertained by the board of health was reported as 4 plus. Treatment was begun, 1.5 cc. of a bismuth compound being given intramuscularly on November 30 and December 2, 8 and 15. This was alternated with neoarsphenamine intravenously, 0.45 Gm. on December 5 and 12, which was tolerated well. December 19, 0.6 Gm. of arsphenamine was administered intravenously with apparently no immediate ill effects. About twelve hours later the patient began to experience a "jumpy" sensation around the heart, which occurred rather frequently but did not interfere with his work. Examination revealed a marked degree of irregularity with extrasystoles and superimposed beats. The blood pressure was 130 systolic and 70 diastolic. No more neoarsphenamine was given, and the patient is now on a regimen of iodides and mercury and bismuth preparations. The cardiac irregularity persists at the present writing. Would you consider the development of the cardiac signs as evidence of a latent syphilitic myocarditis, activated by the arsenical? What effect would nicotine through the use of chewing tobacco have on the heart? What course of treatment would you outline in view of the condition that has developed? Would you kindly furnish references in the literature pertinent to the development of cardiac irregularities after the use of arsphenamine? Please omit name.

M.D., New York.

Answer.—Syphilitic aortitis is a frequent complication of late syphilis. The information provided in the query as to the patient's physical status before treatment omits two or three important points on which the diagnosis depends. In a patient with known late syphilis, the presence of any three of the following criteria is strong evidence in favor of the diagnosis of syphilitic aortitis: (1) teleroentgenographic and fluoroscopic evidence of aortic dilatation, (2) increased retromanubrial dulness, (3) a history of circulatory embarrassment, (4) a tympanitic bell-like tambour accentuation of the aortic second sound, (5) progressive cardiac failure, (6) substernal pain and (7) paroxysmal dyspnea. Syphilitic myocarditis is probably rare, the myocardial changes that occur in patients with syphilitic heart disease being usually due to the mechanical effects of circulatory embarrassment.

The occurrence of persistent extrasystoles after several injections of neoarsphenamine suggests that the patient may have an unrecognized syphilitic aortitis, and it would be safer to treat the patient as if this diagnosis were definite. This is in spite of the fact that the excessive use of chewing tobacco may cause ventricular extrasystoles as readily as excessive smoking.

In view of the presumptive diagnosis of syphilitic aortitis, it would be advisable to keep the patient on bismuth preparations and potassium iodide for two or three months before any effort is made to give further arsenical drugs. When arsenical drugs are resumed, either neoarsphenamine or sulpharsphenamine bismuth may be used. The dose of neoarsphenamine should not exceed 0.45 Gm. Further treatment should be carried on as outlined in a paper by J. E. Moore and J. H. Danglade on the treatment of cardiovascular syphilis (*Am. Heart J.* **6**:148 [Oct.] 1930). A fluoroscopic and teleroentgenographic examination of the cardiovascular stripe should be done promptly. The further use of alcohol and tobacco should be prohibited.

Cardiac irregularities after the use of the arsphenamines are uncommon and usually occur in patients with preexisting cardiovascular syphilis. The following references may be consulted:

Reid, W. D.: The Mechanism of the Toxic Action of Arsphenamine on the Heart, The Journal, March 21, 1925, p. 883.

Wilson, F. N.; Wile, U. J.; Wishart, S. W., and Herrmann, G. R.: Changes in the Electrocardiogram Following the Arsphenamine Treatment of Cardiac and Aortic Syphilis, *Proc. Soc. Exper. Biol. & Med.* **23**: 275, 1926.

DIGESTIBILITY OF COW'S MILK

To the Editor:—Is there a test which can be applied to a cow's milk to determine how digestible that certain milk is? If so, what is the test, how is it made and just how dependable is it? An intelligent dairyman stated that Dr. Abt of Chicago had recommended the test and that herds had been accumulated all the cows of which gave milk that was easily digested. He also stated that such cows gave such milk throughout their entire lives. He was contemplating getting several cows of this sort and advertising their milk for babies only. The cows he already has are all Jerseys and give a milk high in butter fat and for that reason I have not recommended his milk for my feeders. If such cows do exist, would it be safe to feed a baby a milk with a high butter fat content? I must say that this is all new to me in spite of the fact that I have been doing pediatric work for years and try my darndest to keep in sight of the parade at least. Please omit name.

M.D., Arkansas.

Answer.—There is probably no satisfactory test that can be applied to cow's milk to determine its digestibility. Cow's milk derived from the various races of animals differs in the quantity of fat as well as in protein content.

Van Slyke and Publow give the following analyses: Jersey milk contains 5.78 per cent fat; Guernsey, 5.38 per cent; Ayrshire, 3.76 per cent; Holstein, 3.26 per cent. In addition to this the fat globules in Holstein and Ayrshire milk are small, while those of Guernsey and Jersey milk are considerably larger. The digestibility of the milk in all probability does not depend on these factors alone.

In this connection, however, the bulletin of the Utah Agricultural Experiment Station for June, 1928, written by R. L. Hill, calls attention to an apparatus for measuring curd tension, which is a measure of toughness or softness of the milk curd. Hill believes that he found by this method a plan for determining the digestibility of cow's milk by babies. He believes that the milk with a low curd tension is more readily digested than the milk with a high curd tension, and he observes further that, after having examined many breeds of cattle, all show both extremes in curd tension. He assumes that the curd character of the milk is not a breed characteristic. However, a larger percentage of some breeds give soft curded milk than others. He also thinks that the presence of butter fat in milk tends to soften the curd, and that the fat content of the milk is not an index of its curd character. It is generally agreed that boiling milk increases its digestibility.

It seems fair to assume, however, that the mere softness or hardness of the milk curd will not completely solve the problem of digestibility of cow's milk. The digestive ferments of the infant have been planned to digest breast milk and consequently there may be occasional difficulties on the part of the baby in the digestion of any foreign milk. The digestion of the infant will always depend on the proper development of the necessary ferments in quantity and quality, and its tolerance for food will depend on a sufficient quantity of ferments and on the rapidity of their action.

But, in addition, there are well authenticated cases of cow's milk idiosyncrasies manifested by shock, pallor, vomiting, fever and diarrhea; also skin eruptions, such as urticaria, edema and even purpura. Whether such manifestations would be increased by hard curd or diminished by soft curd is doubtful. It is more reasonable to think that these untoward allergic symptoms depend on a foreign protein reaction.

In the evolution of infant feeding, cow's milk has been peptonized, citrated, precipitated with rennin and reemulsified, and in spite of all these measures some babies have failed to thrive on these foods. In other words, the digestibility of cow's milk, as has just been pointed out, depends on the physiologic function of the baby's digestive tract as well as on the physicochemical characteristics of the milk.

TOXIC EFFECTS FROM DUCO

To the Editor:—I should like some information as to the toxic effect of Duco paint and if there have been any cases reported of toxic amblyopia as an occupational disease among Duco painters. Any literature on this subject that you may cite will be appreciated.

J. W. Shelton, M.D., Oklahoma City.

Answer.—The term "Duco" properly applies only to certain products of the du Pont Company. The exact composition of these coatings is not widely known. Duco consists largely of the acetates of amyl, butyl and ethyl with the diluents denatured alcohol, toluene, butyl alcohol and amyl alcohol. As regards the health features, Duco is not generally different from pyroxylin lacquers that have been in use for many years. A number of cases of poisoning from the use of Duco are mentioned in medical literature. The references follow:

Minnesota Med. J. **9:** 703 (Oct.) 1928.
South. M. & S. J. **90:** 752 (Nov.) 1928.

It is probable that a much greater variety of solvents, thinners and other ingredients enter into some coatings. The following substances have been found in coatings of this general character: methyl (wood) alcohol, isopropyl alcohol, diacetone alcohol, acetone, isopropyl acetate, glycols, lactates, benzene, toluene, xylene, naphtha, tricresyl phosphate and others. Manifestly, methyl alcohol, and to a lesser degree ethyl alcohol, may produce a toxic amblyopia, given sufficient exposure to intake by mouth, lungs or skin. The most likely source of current information is the Committee on Volatile Solvents of the American Public Health Association, which may be approached through its chairman, Dr. Elizabeth B. Bricker, Department of Labor, Harrisburg, Pa.

PERIPHERAL NEURITIS AFTER ARSPHENAMINE

To the Editor:—A man, aged 60, had papulomacular eruptions of secondary syphilis. The Wassermann and Kahn reactions were both 4+. He was given immediately neoarsphenamine, two treatments of 0.6 Gm. and four treatments of 0.9 Gm., followed with ten injections of a mercury compound. Just before the beginning of the mercury treatment he complained of tingling in the finger tips of both hands, more severe on extension of the hand and arm, together with some anesthesia of the palmar surfaces of the fingers. He was in today for a mercury treatment and the symptoms are more noticeable, with extension along the course of the radial nerve in both forearms. He also complained of numbness of the second and third toes on both feet. These symptoms are not severe enough to incapacitate the patient, but they are annoying and seem to be getting progressively worse. There is no Argyll Robertson pupil, the Romberg sign is positive, and the reflexes are normal except that in the right leg they are slow and sluggish. The patient says that the right foot bothers him more than the left. Could the central nervous system become involved at this stage with vigorous treatment with involvement of the posterior roots? Could this be a neuritis due to arsenic from the treatment? As I understand it, secondary lesions of syphilis, early after primary infection, as in this case, are evidence of spirochetal septicemia. If this is true, it seems that the neoarsphenamine would have prevented the central nervous system involvement this early. Please inform me on this case as to diagnosis and treatment. Please omit name and address.

M.D., Kentucky.

Answer.—Peripheral neuritis from arsphenamine is rare but it does occur and the history given indicates it. Antisyphilitic treatment should be suspended and sodium thiosulphate given intravenously daily, in increasing doses beginning with 0.1 Gm. and increasing to 1 Gm. When this dose is reached the treatment should be given only every second day. If not well borne, it should be stopped. The U. S. P. drug should be employed. After several weeks of such treatment, iodides should be given for several weeks, or they can be given at the same time as the injections of the sodium thiosulphate. The parts affected should be kept at rest as nearly as possible, with some form of counterirritation along the affected nerves. After the symptoms of nerve involvement have disappeared, which may take a long time, antisyphilitic treatment should consist of alternating courses of mercury and bismuth compounds, arsphenamine being avoided. Treatment should be mild. Patients of 60 cannot stand the strenuous treatment appropriate for younger ones.

SINUSITIS AND DEAFNESS AS BASIS FOR COMPENSATION

To the Editor:—A man contracted sinusitis during army service. This has continued and lately he has been in poor condition. Please advise me whether the sinusitis would be a probable cause for the deafness, which has gradually developed, and whether it could cause a valvular heart condition or aggravate a previously existing but unknown lesion. Should he be entitled to compensation only for sinusitis, service connected, or should he also claim compensation for either or both of the other conditions as indirectly service connected by reason of a causative factor in the sinusitis?

H. F. Curtis, M.D., Concord, N. H.

Answer.—This sinusitis, which must have persisted for at least thirteen years as it was contracted in the army service, could be the cause of deafness of a catarrhal type. Such deafness, however, is seldom profound, and, should examination of hearing function reveal that the cause of the deafness lies in an involvement of the internal rather than of the middle ear, the chronic sinusitis is probably not the cause. There is a great deal of debate as to whether or not suppuration in the accessory nasal sinuses may act as a focus of infection. The better conservative opinion inclines to the belief that these lesions do not act nearly as often in this capacity as do others, namely, those about the roots of teeth and in the tonsils. It is possible but not probable that a valvular heart condition either springs from or is aggravated by chronic suppurative sinusitis. This individual is certainly entitled to compensation for sinusitis, service connected, and he may be entitled to compensation for the valvular heart condition, but it is highly questionable whether he should be compensated for the latter on the basis that it springs from or is aggravated by the former.

X-RAY DERMATITIS OF SCROTUM

To the Editor:—What effect may result from an x-ray burn on the scrotum? The x-rays were used for the sole purpose of preventing conception. The patient is a man, aged 50. Please omit name.

M.D., Indiana.

Answer.—If the radiodermatitis is of the acute type and of the third degree, it may be associated with severe pain and result in an indolent ulcer. If the ulcer is small, it may heal spontaneously in a few months or a year. If it is large, it may never heal and eventually give rise to malignant cancer. An acute burn of the first or second degree may give rise eventually to x-ray sequelae such as atrophy, telangiectasia and keratoses, and the latter may give rise to malignant cancer. Depending on the amount of x-rays administered, the sterility may be temporary or permanent.

If the radiodermatitis is of the chronic type consisting of x-ray sequelae such as atrophy, telangiectasia and keratoses, the latter may give rise to malignant cancer in anywhere from a few months to twenty years. So-called x-ray skin (chronic radiodermatitis) may at any time ulcerate. Such ulcers may heal spontaneously or they may become indolent and eventually change to malignant cancer.

DANGER FROM HYDROGEN CYANIDE

To the Editor:—I should like to know the danger of hydrocyanic acid formation or any other attendant health hazard from the following procedure: Small steel parts are washed in a 20 per cent sulphuric acid, electrolytic bath, from 2 to 8 volts and from 3 to 5 amperes being used. It has been suggested that these parts be transferred to an electrolytic bath of from 1.25 to 3 per cent sodium cyanide at 180 F. It would seem as though there is definite danger of hydrogen cyanide formation from this bath despite the efficient blower system installed. If this danger exists, would an intermediate bath of hot or cold water or alkali, or combination of both avert this menace? Please use initials only.

M.D., Connecticut.

Answer.—The amount of sulphuric acid carried over from the first to the second bath will largely determine the amount of hydrogen cyanide formed. In the absence of acid, traces of hydrogen cyanide may be formed by hydrolysis, but the amount so produced ordinarily will be taken care of by an efficient blower. Between the two baths, the steel parts should be washed one or more times with hot alkali solutions. It is possible that hot sodium carbonate solutions may serve this purpose. This introduces another but lesser hazard from the sodium carbonate, which is a skin irritant. Sodium bicarbonate solutions are preferable for this purpose, if no industrial incompatibility arises. At any rate, no sulphuric acid should be carried over into the sodium cyanide electrolytic bath.

TRAUMATIC MASTOIDITIS

To the Editor:—Kindly advise me as to the incidence of traumatic mastoiditis. I was called to see a girl, aged 10 years, who was injured, Nov. 13, 1931, by a ladder falling from a roof. The ladder struck her on the left side of the head over the temporal region. Since the injury the child has had attacks of dizziness and violent headaches on the left side. January 6, the left ear began to discharge. Headache and dizziness are still present. There is extreme tenderness over the mastoid antrum, with sagging of the postsuperior canal wall. There is no evidence or history of any preceding sore throat, cold or infection of the upper respiratory tract. I should greatly appreciate some data on this problem.

M.D., Mass.

Answer.—Traumatic mastoiditis in civil life does not occur often, though a number of cases have been reported of mastoiditis following injury of one sort or another. The condition then is often comparable to that of an osteomyelitis in other parts of the body following injury, as noted in the extremities, for instance. After the suppurative process in the mastoid has begun, infection may extend by way of the mastoid antrum and aditus ad antrum into the middle ear and give rise to symptoms of acute otitis media. On the other hand, the process may remain limited to the mastoid bone itself without visible changes of hearing. When definite signs and symptoms of involvement of the mastoid process are present, the operative procedure would be the same as when due to some infection extending to the mastoid cells from the middle ear.

DICK TEST FOR IMMUNITY TO SCARLET FEVER

To the Editor:—Since reading of the work of Rhoads on scarlet fever immunization (The Journal, July 18, 1931) in which he used the five dose scarlet fever toxin preparations approved by the Scarlet Fever Committee, I have been advocating immunization by this method. Some of the local physicians do not approve of it, and I have met considerable opposition since I have recommended this method of immunization. I have read the literature on the subject, and all the reports that I have found have been favorable. Have there been any unfavorable reports as to severe reactions from these approved preparations or as to failures to produce immunity? Is there any doubt at present that the Dick test is a reliable indicator of immunity to scarlet fever?

R. K. Schmitt, M.D., Columbus, Ind.

Answer.—There have been no unfavorable reports as to the results of immunization against scarlet fever by injection of the five graduated doses of the scarlet fever toxin as described in the Rhoads article. There is no doubt that the Dick test correctly made with accurately standardized toxin and observed between twenty and twenty-four hours after the intradermal injection is a reliable indicator of immunity to scarlet fever.

TREATMENT OF LATE SYPHILIS

To the Editor:—A man, now about 60, contracted syphilis from thirty to thirty-five years ago. It was not diagnosed or treated. There is no history of symptoms until about four months ago, when two cutaneous gummas appeared. He consulted me three weeks ago with ulcers where the gummas had broken down, and a 4+ Wassermann reaction. His nervous system and heart are apparently normal; the kidneys are not so good; the arteries are sclerotic, and the teeth and gums are very bad. On potassium iodide, 15 grains (1 Gm.) three times a day, the ulcers have healed. I have referred him to a dentist. What different treatment, if any, is indicated? What is your opinion of bismarsen? Please omit name.

M.D., Connecticut.

Answer.—A man, aged 60, with some kidney impairment must be treated with extra caution. As soon as the tooth infection is cleared up, more active treatment should be given, either mercury or bismuth compounds with small doses of arsphenamine, neoarsphenamine or sulpharsphenamine bismuth (bismarsen). The latter is a valuable and reliable antisyphilitic, suitable for the case in question. The same reactions as are seen with the other forms of arsphenamine must be watched for, and in a patient of this age the state of the kidneys, liver and heart is to be carefully watched. The treatment should be mild.

ETHER IN WHOOPING COUGH

To the Editor:—May I receive information as to the dosage of ether in olive oil, by rectum, the frequency of application, and contraindications, in whooping cough? In the coughs of children, is papaverine more sedative than codeine? Please omit name.

M.D., New York.

Answer.—Equal parts of ether and olive oil are employed except in patients under 1 year of age, when a mixture of 1 part of ether and 3 parts of oil is given. The usual dose is 2 cc. of ether for each year of apparent age, given two, three or even four times daily through an 18 or a 20 (French) rubber catheter for from five to twelve days, according to the response of the patient. Desire to defecate is antagonized by pressure against the anus and elevation of the hips. If, in spite of these precautions, the child defecates within thirty minutes after the injection, the dose is repeated. No contraindications have been noted.

Codeine is more sedative than papaverine in coughs.

LUPUS ERYTHEMATOSUS

To the Editor:—A boy, aged 8 years, had his whole face sunburned two years ago. The parents noticed six months after the burn that, although the face was normal in appearance, the nose was rough. He has been seen by several physicians and treated with salicylic acid, fractional doses of x-rays, and so on. Treatment has had no effect on the lesion. The lower half of the nose is affected in a geographic manner. The skin has a rough appearance, but no scales are present. The color is slightly darker than the normal skin. There are no other lesions on any part of the body. What would be the probable diagnosis and what treatment advisable? Please omit name.

M.D., Texas.

Answer.—The onset after sunburn, location on the nose, roughness without scales and the "geographic" outline suggest a mild lupus erythematosus. The patient should be seen by a skin specialist and a definite diagnosis made made before any treatment is undertaken.

USE OF PHENOL IN NOSE

To the Editor:—My attention has been called to the harmful effects of phenol on the mucous membranes of the nose. The phenol was used as a nasal spray in the strength of approximately 0.5 per cent. Are there any harmful effects to be expected from phenol in this strength, and if so, what are they? Please omit name and city.

M.D., Michigan.

Answer.—Apparently, no definitely harmful effect on the nasal mucous membrane from the use of 0.5 per cent phenol has been noted. As a matter of fact, for many years the late Dr. Sluder of St. Louis used instillations of 0.5 per cent phenol in oil and claimed that only beneficial effects were obtained thereby. Phenol is freely soluble in glycerin and is not precipitated; but when it is dissolved in oil and then allowed to stand, there is some danger of precipitation, so that the lower portion of the solution is more concentrated and might be irritating. It is best, therefore, when administering an oily solution to shake it before using.

"HATBAND" DERMATITIS

To the Editor:—Please inform me whether or not there is any remedy for the so-called hatband dermatitis. For several years I have been seriously annoyed by an itching eruption across my forehead, caused by wearing a hat, and cured only by leaving off hats altogether for a month or more. The area affected, when at its worst, is dry, scaly, red, and covered with very small hard pimples. Lining a hat with cloth aids, but does not prevent, the trouble. My age is 55. Please omit name.

M.D., Illinois.

Answer.—Lining the hat with cloth may fail to bring relief because of perspiration carrying the irritating substance through the cloth. If a small piece of the hatband is fastened on the normal skin for forty-eight hours, a person who is sensitized to this leather will possibly present a patch of dermatitis; or it may be necessary to test the skin of the forehead. Fractional doses of x-rays, one-fourth erythema dose once a week, will hasten the cure of the dermatitis. Then ultraviolet rays should be used until the skin is well tanned. Then a hat with a band made of a different kind of leather should be worn.

USE OF CONVALESCENT WHOLE BLOOD IN MEASLES

To the Editor:—How efficacious and how lasting is the prophylactic treatment of measles by the intramuscular injection of whole blood from an adult or a convalescent patient?

H. C. Liu, M.D., Honolulu, Hawaii.

Answer.—Most reports are favorable as to the effectiveness of prophylactic injections of whole blood from convalescent measles patients or normal adults who previously have had measles. Blood from convalescent patients gives somewhat better protection than blood from normal adults. From 96 to 98 per cent protection may be obtained by the use of pooled *convalescent serum* or whole blood, if given within five days after exposure. The passive immunity procured from such injections is transient, lasting from two weeks to two months. If blood is given between the fifth and the eighth day after exposure a modified form of measles generally results, usually not followed by complications. The immunity following an attenuated attack of measles is probably permanent.

Council on Medical Education and Hospitals

COMING EXAMINATIONS

AMERICAN BOARD FOR OPHTHALMIC EXAMINATIONS: New Orleans, May 9. Montreal, Sept. 19. Sec., Dr. William H. Wilder, 122 S. Michigan Ave., Chicago.

AMERICAN BOARD OF OBSTETRICS AND GYNECOLOGY: Written examinations will be held in nineteen cities of the United States and Canada, March 26. The general, oral and clinical examination will be held in New Orleans, May 10. Sec., Dr. Paul Titus, 1015 Highland Building, Pittsburgh.

AMERICAN BOARD OF OTOLARYNGOLOGY: New Orleans, May 9. Sec., Dr. W. P. Wherry, 1500 Medical Arts Bldg., Omaha.

ARIZONA: Phoenix, April 5-6. Sec., Dr. B. M. Berger, 12 N. Central Ave., Phoenix.

COLORADO: Denver, April 6-9. Sec., Dr. Wm. Whitridge Williams, 422 State Office Bldg., Denver.

CONNECTICUT: *Endorsement*. Hartford, March 22. Sec., Dr. Thomas P. Murdock, 147 W. Main St., Meriden.

IDAHO: Boise, April 5. Comm. of Law Enforcement, Hon. Emmitt Pfost, Boise.

ILLINOIS: Chicago, April 12-14. Supt., Mr. Paul B. Johnson, Springfield.

MINNESOTA: *Basic Science*. Minneapolis, April 5-6. Sec., Dr. J. C. McKinley, 125 Millard Hall, University of Minnesota, Minneapolis. *Regular*. Minneapolis, April 19-21. Sec., Dr. E. J. Engberg, 524 Lowry Bldg., St. Paul.

MONTANA: Helena, April 5. Sec., Dr. S. A. Cooney, Power Block, Helena.

NEW MEXICO: Santa Fe, April 11. Sec., Dr. P. G. Cornish, Jr., 221 W. Central Ave., Albuquerque.

RHODE ISLAND: Providence, April 7-8 Dir., Dr. Lester A. Round, 319 State Office Building, Providence.

TENNESSEE: Memphis, March 23-24. Sec., Dr. Alfred B. DeLoach, Medical Arts Bldg., Memphis.

WEST VIRGINIA: Charleston, March 22. Sec., Dr. W. T. Henshaw, Charleston.

WISCONSIN: *Basic Science*. Madison, March 19 Sec., Prof. Robert N. Bauer, 3414 W. Wisconsin Ave., Milwaukee. *Reciprocity*. Milwaukee, April 6. Sec., Dr Robert E. Flynn, 315 State Bank Bldg., LaCrosse.

New York June Report

Mr. Herbert J. Hamilton, chief, Professional Examinations, reports the oral and written examination held at Albany, Buffalo, New York and Syracuse, June 22-25, 1931. The examination covered 9 subjects and included 10 questions. An average of 75 per cent was required to pass. Six hundred and seventy candidates were examined, 585 of whom passed and 85 failed. The following colleges were represented:

Book Notices

Tumors of Bone. By Charles F. Geschickter, M.D., Surgical Pathological Laboratory, Department of Surgery, Johns Hopkins Hospital and University, and Murray M. Copeland, M.D., Memorial Hospital, New York City. With forewords by Dean Lewis, M.D., Professor of Surgery, Johns Hopkins Hospital and University, and Joseph Colt Bloodgood, M.D., Clinical Professor of Surgery, Johns Hopkins Hospital and University. Cloth. Price, $5. Pp. 709, with 406 illustrations. New York: American Journal of Cancer, 1931.

This is the first book published under the auspices of the *American Journal of Cancer*. It is a welcome visitor and, it is hoped, will be the precursor or forerunner of others. The volume reflects many of the teachings of the authors' great teacher, Bloodgood, who gave them the opportunity and material. The work covers completely the field of bone tumors and is based on a study of more than 3,600 cases. It gives in detail the clinical picture, roentgenologic features, prognosis, treatment and pathology of the various neoplastic entities. A separate complete chapter is devoted to each type of tumor. Special emphasis is placed on differential diagnosis and the interpretation of roentgenograms. A summary is included in every chapter. The illustrations serve as an atlas of bone tumors. In the foreword, by Dean Lewis, the statement is made that in any case in which a mutilating operation is to be performed a biopsy should be made. If there is any doubt, final judgment should be reserved until the best section that can be prepared is carefully and competently studied. In the second part, Bloodgood states his rules of procedure in regard to bone tumors. The authors emphasize the relationship between bone development and tumor formation, and it will be found that the clinical entities described rest on the type and phase of tissue differentiation represented by the new growths.

The authors state that approximately half of all the primary neoplasms of the bone are related to precartilaginous connective tissue. This combination or transition from connective tissue to cartilage and to bone, seen in all these tumors, not only repeats the sequence by which the skeleton is derived in the embryo but recalls the order of development of the spine in vertebrates and demonstrates effectively the relationship of tumors of the bone to both evolution and embryology. The authors contest the idea that malignant variants of the giant cell tumor arise by gradual transformation from benign giant cell tumor. They believe that these are always forms of osteogenic sarcoma with giant cells that produce bone destruction. The discussion of extraskeletal giant cell tumors includes epulis and xanthoma. The authors state that there are two types of sarcoma of soft parts which are prone to invade the bone by direct extension: fibrosarcoma and neurogenic sarcoma. Both these malignant forms cast a soft part shadow in the roentgenogram and produce osseous destruction, eroding the bone from without inwardly. Bone changes in chloroma and Gaucher's disease are given consideration. In a supplement, Bloodgood considers the therapeutic measures in lesions of bone.

There is a two-page chart on the roentgenographic diagnosis of diseases and tumors of bone, illustrating the salient features of bone diseases and bone tumors. There are chapters on the differential diagnosis of neoplastic and non-neoplastic bone conditions, discussing osteomyelitis, tuberculosis, syphilis, and uncommon diseases of bone, including Brodie's abscess, Garré's *nonsuppurating osteitis, ossifying periostitis,* traumatic myositis ossificans, melorheostosis, osteitis deformans and osteomalacia. Another chapter concerns juvenile bone lesions, including scurvy, rickets, congenital syphilis, osteogenesis imperfecta, fragilitas ossium and marble bones.

The illustrations, including diagrams, roentgenograms and gross and microscopic sections, are numerous and excellent. This long awaited book is a welcome addition to our literature. It can be recommended highly to general surgeons, roentgenologists, pathologists and orthopedic surgeons.

Untersuchungen über das Wirbelgleiten. Von Prof. Hermann Meyer-Burgdorff, Oberarzt der chirurgischen Univ.-Klinik, Rostock. Paper. Price, 15 marks. Pp. 136, with 155 illustrations. Leipzig: Georg Thieme, 1931.

This monograph is the latest on the subject of spondylolisthesis. While the subject is an old one, little literature had accumulated until recently. The author discusses the pathology of spondylolysis and the slipping and the static changes in the pelvis and vertebral column. In an interesting chapter on etiology he attributes most cases to an acquired spondylolysis. The fissure is the result of a chronic bone change (umbau) aided by the lordosis. It may follow vertebral fracture of the lower thoracic and upper lumbar spine. In the chapters on clinical symptoms and on roentgen diagnosis, the author gives numerous detailed case histories. The book closes with a discussion of differential diagnosis and therapy. Spondylolisthesis is an important cause of pain in the back. It may be concealed by symptoms that are not characteristic. Further studies are necessary in the etiology and diagnosis of spondylolisthesis, especially its relation to congenital fissures, the occurrence of fractures of the vertebral arch after trauma and fractures of the vertebra, the course of the dislocation and its spontaneous cure. The greatest aid in the study of these conditions has been the advance in roentgen technic. The author has studied 40 cases of spondylolisthesis and 143 suspected cases. He finds the spondylolisthesis is not really a disease but rather a symptom, which the close observer often discovers incidentally or accidentally. Even in advanced cases the clinical symptoms may not be typical without the roentgen observations. Hence the emphasis in this monograph on the roentgen examination of the patient. The object of the book is to correlate the author's own studies with the known clinical symptoms and the literature on the etiology. The condition was described by Herbinaux in 1782, Rokitanski in 1836 and Kiebisch in 1851. The term spondylolisthesis was coined by Kilian, who considered the condition a gradual dislocation or slipping. In reality, only the body and anterior portion of the arch slip, while the posterior arch and spinous process remain in their old position. The work of Neugebauer, published in 1881, summarized all that was known of the etiology and pathologic anatomy. He was the first to demonstrate that a symmetrical or asymmetrical separation in the arch, at the level of the so-called interarticular portion, must precede the slipping, and that this cleft formation develops in every spondylolisthesis. He looked on the fissure formation as congenital. Meyer-Burgdorff concludes that spondylolisthesis is due to an acquired chronic bone change with fissure formation in the arch and is not congenital; a marked lordosis, and an increased superimposed load on the transverse articulations. Forces acting on the arch in the lumbosacral region are contributing factors. Only rarely is trauma the cause, and then a very severe injury with luxation or subluxation. The condition may be aggravated by a severe injury. Spondylolisthesis often follows fractures of the spine from the eleventh thoracic to the first lumbar, with the resullumbar lordosis and changes in the transverse articulations and adjacent portion of the arch which lead to fissure formation. Treatment should be conservative. The condition tends toward healing after a rest period. Operation accomplishes a similar result and is advisable in severe cases. The illustrations, which include roentgenograms and diagrams, are profuse and excellent. Oblique roentgenograms of the lumbosacral region are shown. The bibliography is extensive. The book should be of value to orthopedic surgeons, roentgenologists and industrial surgeons.

Report of the Preparatory Committee on the Principles Governing the Organisation of Medical Assistance, the Public Health Services and Sanitation in Rural Districts. European Conference on Rural Hygiene. League of Nations, Health Organisation. Series of League of Nations Publications, III. Health, 1931. III. 7. Official No. C. H. 1045. Paper. Price, 2/-; 50 cents. Pp. 62. Geneva: League of Nations; Boston: World Peace Foundation, 1931.

European Conference on Rural Hygiene (June 29th to July 7th, 1931). Volume I: Recommendations on the Principles Governing the Organisation of Medical Assistance, the Public Health Services and Sanitation in Rural Districts. League of Nations, Health Organisation. Series of League of Nations Publications, III. Health, 1931. III. 11^1 Official No. C. 473. M. 202. 1931. III. Paper. Price, 50 cents. Pp. 59. Boston: World Peace Foundation; Geneva: League of Nations, 1931.

In 1930 a committee composed of the leading health workers of Europe was appointed by the League of Nations to study the problem of rural health. The three items mentioned in the title were submitted to different groups of experts, numbering more than fifty in all; their findings are published in the Report of the Preparatory Committee. Later a conference was held at Geneva to which twenty-three European countries sent delegates, and eight countries, including the United States, sent observers. The recommendations of the conference are found in volume I, while the minutes of the conference will appear in volume II. Two thousand persons is the maximum number in a rural community who can be given proper medical attention by a duly qualified medical practitioner. It is desirable that there be a sufficient number of pharmacists to insure proper dispensing of drugs, and of nurses or other qualified auxiliary personnel to work under the direction of the physician. Dispensaries, hospitals and laboratories should be at the disposal of the physician where possible. The public health officer must be a qualified physician but must divorce himself from the private practice of medicine. His rural territory should contain on the average 50,000 inhabitants with a medical assistant for each additional 50,000 of population, and the necessary public health nurses, sanitary inspectors and clerks; the importance of rural health centers is stressed. Sanitation in rural districts is discussed under the headings of sewage disposal, water supply, housing and land improvements. A chapter in the report of the preparatory committee is devoted to sickness insurance as a factor in rural hygiene, prepared by the International Labor Office. A perusal of the two pamphlets makes one realize that the principles of preventive medicine are the same the world over, but methods of practice may vary radically in different countries, according to local conditions. The recommendations were prepared from the result of practical experience, and, while intended primarily for European countries, contain much of value for physicians and health officers in the United States.

Lehrbuch der Röntgendiagnostik. Von H. R. Schinz, W. Baensch und E. Friedl. Nebst Beiträgen von M. Holzmann, A. Hotz, O. Jüngling, E. Liebmann, E. Looser und K. Ulrich. Band I: Skelett; Band II: Innere Organe. Third edition. Paper. Price, 214 marks, per set. Pp. 1-704; 705-1623, with 2714 illustrations. Leipzig: Georg Thieme, 1932.

This is as fine a reference book as is available in any language on roentgen diagnosis. The first volume deals with roentgenologic studies of the osseous system and the second with the internal organs. In addition to a thorough picture of the roentgen observations, the authors have frequent chapters on the associated pathologic changes and the conditions revealed by operation. Full credit is given to the contributions in all other lands, especially America, France and Sweden. There is an excellent chapter giving the latest work in the field of gynecology and pyelography. Many of the roentgenograms have associated sketches of the details for the sake of clearness for one not especially trained in x-ray work. The book is not only excellent for students and practicing physicians but is an exhaustive reference book for radiologists.

Lowered Basal Metabolism—Its Causes and Clinical Significance. By Bernard M. Jacobson, M.D. Fiske Fund Prize Essay, No. 65. Cloth. Pp. 40. Providence, R. I.: Fiske Fund Prize Essay, 1931.

This pamphlet won the Fiske prize of $200 in 1930. It is a study of basal metabolism from the theoretical and clinical points of view. Jacobson defines low basal metabolism "as that caloric output determined under standard conditions which, when compared with the accepted standards of normal metabolism, is definitely depressed." Attention is called to the deficiencies and errors in computing basal metabolism because of the lack of sufficient standards in the very young and old, the variations of metabolism produced by sleep and the different results obtained, depending on whose standard is adopted. He rightfully points out an interesting fact that often a lowered metabolic rate may be the normal rate for that individual. The appearance of symptoms of hyperthyroidism is then accompanied by what is accepted as the normal rate but in fact is an increased rate for that individual. Such information is not new to those acquainted with variations in temperature elevation and blood pressure. There are chapters on the physiologic causes of low basal rate, such as race, climate, sleep and the pathologic causes, as cretinism, myxedema and postoperative hypothyroidism. The author discusses the pulse, the blood pressure, electrocardiograms, respiratory minute volume, spinal fluid, perspiration, cholesteremia, the effects of lowered metabolism on body weight, and their association with diseases of other endocrine glands, nephrosis, anemia and certain diseases of the nervous system. The work does not represent original investigation but is the result of a careful study of the literature. The bibliography is extensive. No claim can be made for this little volume as a contribution to our knowledge but it represents the type of critical work of the young man that should be encouraged.

Oclusión coronaria brusca y lenta. Por los Doctores T. Padilla, professor suplente de la Facultad de Medicina, y P. Cossio, venia docente de la Facultad de Medicina. Prólogo del Prof. C. Bonorino Udaondo. Paper. Pp. 268, with 94 illustrations. Buenos Aires: "La Semana Medica," Imp. de obras de E. Spinelli, [n. d.].

The authors state that the first report on a case of coronary occlusion in Argentina was in 1927. It seems remarkable, therefore, that within four years from that time there would appear two such excellent monographs on this subject as the one by Battro, which was reviewed a few months ago, and the present volume. The present volume contains an unusually good and comprehensive digest of the subject. This is based on a personal experience with thirty-three cases and a familiarity with the literature both early and recent. The manner of presentation is scholarly, clear, concise. After an interesting historical review the anatomy and physiology of the coronary artery are discussed, there being several helpful diagrams. Then follow chapters on experimental work, pathology and etiology. The second part of the work is devoted to clinical features, classification, complications and results of occlusion, diagnosis, prognosis and treatment. Much attention is paid to electrocardiography and there are many illustrations covering this phase of the subject. One feature that distinguishes this book is that the authors do not limit their discussion to the acute forms of coronary occlusion but consider as well the slowly developing types. They also aim to show the relation between the anatomic lesions and the resulting symptoms. In fact, as is stated in a prologue written by Udaondo, this is the fundamental idea of the book. The authors largely follow the views of Barnes and Whitten as to electrocardiographic identification of the location of infarcts based largely on the work of Parkinson and Bedford. The desire to establish this relation has perhaps led to an overrefinement of classification, a too definite assignment of cases to particular groups and to particular stages of the disease supposedly revealed by symptoms and electrocardiograms. Such classifications, useful as an aid in understanding the subject oneself or in imparting knowledge to others, are often found to be illusory when the attempt is made to apply the rules in practice. There is also a vagueness and uncertainty of the rules for prognosis, though one might find it difficult to substitute anything better. There is an oversanguine advising of polypharmaceutic drug treatment. Yet, taken as a whole, the book is to be commended as a scientific, sane and scholarly contribution to medicine.

Institute for Child Guidance Studies. Selected Reprints. Edited by Lawson G. Lowrey, M.D. Cloth. .Price, $1.50. Pp. 290. New York: Commonwealth Fund, 1931.

The Institute for Child Guidance was organized in 1927 under the auspices of the Commonwealth Fund as a center for training psychiatrists, psychologists and social workers in the technic of child guidance. From time to time various members of the staff have published articles concerning their work. These articles are now collected in one volume for general distribution. The studies are quite practical and will mean much to those interested in child training. They concern not only contributions to the social field but also distinctly medical studies having to do with the complexes, restlessness, delinquency, finger sucking and mental hygiene. One of the most significant essays is the final contribution, by Dr. Lowrey, on the profession of parenthood. It offers a guide and a stimulus to thought for every one who assumes the responsibility for a child's growth and education.

Stereoskopischer Atlas der äussern Erkrankungen des Auges nach farbigen Photographien für Studium und ärztliche Fortbildung mit begleitendem Text. Von Karl Wessely, Professor in München. Lieferung 4, Bild 31-40. Boards. Price, 12 marks. Munich: J. F. Bergmann, 1931.

This is the fourth of the series of colored stereoscopic photographs of diseases of the external eye and is fully up to the standard set by the preceding series. The conditions shown are pterygium, epithelial tumor of the limbus, lacrimal fistula following injury, xerophthalmos following trachoma, melanosarcoma of the choroid, tuberculous iritis, zonular cataract, calcified luxated lens, metallic foreign body in the anterior chamber, and vaccinia of the eyelids. The photographs are actual stereos in color, reproduced by a new process that permits of high color fidelity except in the higher magnification, in which the grains of the photographic emulsion become too plainly visible. Needless to say, the reproductions of the clinical processes are absolutely accurate and the colors add much to the teaching values. On the back of each plate is a short description of the case in English (good English and not "as she is wrote"), German and French.

History of Medicine in the Province of Quebec. By Maude E. Abbott, B.A., M.D. Cloth. Price, $3. Pp. 97, with illustrations. Montreal: McGill University, 1931.

Here is a record of the development of medical science in the province of Quebec from the discovery of Canada in 1534 to the present date. It is based on material collected by Dr. Ahern, which he was prevented from publishing because of death and which covered the period up to 1800. The material since 1800 and all the compilation and writing are the work of Dr. Abbott. The book is handsomely illustrated, but the typography includes a wide column with closely printed type, which makes rather difficult reading. The author has chosen well from the available material, and the data may be depended on as accurate. It is interesting to note that following the introduction of ether in Massachusetts in 1846 it was used in an operation on a woman in Montreal in January, 1847. Several brief biographic sketches are of particular interest and the facts regarding various hospitals, societies and periodicals are all made available.

Le pouls alternant: Étude clinique et essai de pathogénie. Par Marcel Poumailloux, chef de clinique à la Faculté de médecine de Paris. Préface du Dr. Ch. Laubry. Paper. Price, 35 francs. Pp. 239, with 18 illustrations. Paris: Masson & Cie, [n. d.].

The author rehearses the views of former writers, such as Gaskell, Hering and Gravier, who have explained the alternating pulse on the basis of abnormal cardiac conditions. These views he regards as invalid in a large proportion of cases. He credits Wenckebach, who advanced the hemodynamic theory, with first calling attention to the rôle of the arteries in pulsus alternans. Poumailloux elaborates this theory, supporting it by clinical and experimental studies. He believes that, in many instances in which an examination of the heart alone by auscultation or electrocardiography fails to show the alternation, a study of the arteries will reveal the seat of the phenomenon. The state of the vascular system, particularly "vascular plethora," together with that of the nerves that regulate the peripheral vessels, should be given more attention if one is to understand this condition. There is a chapter devoted to practical considerations. The author contends that the alternating pulse should not too dogmatically be regarded as of evil omen and as a sure harbinger of early death. It will be interesting to see whether these views are accepted when they are subjected to later experimental and clinical tests by others.

The Mind and Its Body: The Foundations of Psychology. By Charles Fox, Director of the Training of Schoolmasters in the University of Cambridge. Cloth. Price, $3.50. Pp. 316. New York: Harcourt, Brace & Company, 1932.

The author has previously written several excellent contributions to the field of psychology. The present volume is planned to provide a consideration of the subject for advanced readers. The author provides a discussion of various theories in this field and, after considering what has been learned of animal and human psychology, discusses such special topics as the psychology of language and of temperament, the importance of instinct, the meaning of dreams, and hallucinations and illusions. The work is profound and not to be confused with popular considerations. From the point of view of psychology the author defines and explains freedom of the will and offers an understanding of the immortality of the soul. Dr. Fox finds the body and mind so intimately bound that their separation is inconceivable. Nobility of soul arises from the pursuit of what is of permanent worth. Beyond that, he says, "The question of the immortality of the soul can only be discussed in terms of concepts derived from religion."

Semiología de la onda t del electrocardiograma y su interpretación clínica. Por Antonio Battro. Trabajo correspondiente al segundo año de adscripción a la Cátedra de Clínica Médica. Paper. Pp. 121, with 66 illustrations. Buenos Aires: Sebastián de Amorrortu, 1931.

This monograph is based chiefly on a critical survey of the literature. Apparently there is not one of the 167 articles listed in the bibliography to which at least one reference is not made in the text. Besides, the author has made studious observations of his own. The nature of the T wave is discussed together with its variations under normal conditions. Then there are taken up the effects of drugs, heat and cold, together with the alterations due to nervous influences. Following this there is considered the T wave as seen in such diseases as pericarditis, myocarditis, angina pectoris, coronary occlusion and valvular lesions. There are many well selected electrocardiograms. The cardiologist will find the book both stimulating and helpful.

Notes on Children's Nursing. By Marguerite C. Erxleben, R.N., B.S., Director of Instruction, The Children's Hospital of Philadelphia. Fabrikoid. Price, $2. Pp. 242, with 43 illustrations. Philadelphia: F. A. Davis Company, 1931.

This is a concise collection of nursing procedures for the care of children in the hospital and dispensary. The complete and general nursing care in any one ailment is not discussed. For this reason its value is confined to that of a supplementary textbook for student and graduate nurses. The subject matter covered is presented in a clear and efficient manner. The materials required for each nursing procedure are conveniently listed along with a short discussion of the method. The part devoted to nursing care of the premature infant does not appear to be adequate for this highly important branch of pediatric nursing. As a collection of notes on children's nursing it serves its intended purpose, but it will be of practical interest only to those engaged in institutional work.

Manuel des calculs de laboratoire: Précision. Discussion et interprétation des résultats expérimentaux à l'usage des chimistes, biologistes et physico-chimistes. Par H. Vigneron. Préface de P. Pascal, correspondant de l'Institut. Paper. Price, 40 francs. Pp. 183, with 45 illustrations. Paris: Masson & Cie, 1931.

This work is of value to those who desire to review their courses in college mathematics. It deals particularly with methods of calculating results of precision measurements as used in quantitative and in theoretical chemistry. The author takes up for first consideration the important theory of errors in chemical calculations. This is followed by interpretation of experimental results, followed by a more mathematical discussion of interpolations. Considerable space is devoted to the discussion of experimental results from a mathematical rather than a chemical standpoint. This is most appropriately a book for those in close contact with physical or physical-organic investigations

Medicolegal

Physician's Right to Refuse to Treat a Case

(Childers v. Frye (N. C.), 158 S. E. 744)

Childers fell from a rapidly moving automobile. He was picked up unconscious and taken immediately to a hospital operated by the defendant-physician. While he was being removed into the hospital, an attendant asked whether he was drunk. She was told that he might have been drinking, but that he was not drunk. When the physician-defendant first saw the patient he called attention to the fact that he had been drinking and at his suggestion one of Childers' companions smelled Childers' breath. The physician-defendant dressed the patient's right eye, examined his arms and legs, felt his head, and then informed his companions that that was all that he could do. He directed that the patient be taken home, threatening that if that was not done he would turn the patient over to the police. A few hours after the patient reached home, a physician was called in, and later a second physician. The patient died, however, a few days later. His mother, as administratrix of his estate, sued the defendant-physician, on the theory that he failed to make a proper examination of the patient in order to discover the extent of his injuries and negligently abandoned the treatment of his patient. The physician-defendant filed an answer denying that he had accepted the injured person as a patient and alleging that he was brought to the defendant's hospital temporarily in an intoxicated and unconscious condition; that his companions took him home with instructions from the defendant to return him to the hospital after he was sober; and that he was never returned to the hospital, nor was the defendant ever requested to render further services. The patient's companions denied that they had heard the defendant say anything about bringing the patient back to the hospital if he did not get better. A judgment of nonsuit was entered, and the plaintiff appealed to the Supreme Court of North Carolina.

The question of law to which all others are subsidiary, said the Supreme Court, is whether there was sufficient evidence to be submitted to the jury, tending to establish the relationship of physician and patient between the deceased and the defendant. A physician is not bound to render professional services to every one who applies, and he may by notice or special agreement limit the extent and scope of his employment. As a physician cannot make a contract with an unconscious person, the ultimate test of liability in a case like the present one depends on whether the physician actually accepted a person as a patient and undertook to treat him. If there is conflicting testimony, it would be for a jury to decide whether there was or was not such an undertaking or acceptance by the physician. In the present case, all evidence tends to show that when the injured man was brought into the hospital the defendant looked him over and on discovering that the patient had been drinking declined to accept him as a patient or to undertake the necessary treatment. Even if the defendant was not justified in assuming that the patient was drunk, still the law did not compel him to accept the injured man as a patient. Furthermore, there is no evidence tending to show that the refusal of the defendant to accept the injured man as a patient or to make a more thorough examination of him was the proximate cause of his death, especially in view of the fact that the patient was treated by two physicians possessing and employing, so far as the record discloses, all requisite skill and care. The judgment of nonsuit entered in favor of the defendant-physician by the trial court was affirmed.

Malpractice of Dentist Not Provable by Testimony of Physician.—Rawleigh sued Donoho, a licensed dentist, to recover damages for malpractice, alleging that the dentist, in extracting an impacted tooth, fractured his jaw. Rawleigh, the patient, called a licensed physician as a witness. The physician, after stating his professional qualifications and his experience in reading and interpreting roentgenograms, was handed two roentgenograms of the tooth extracted, taken prior to the extraction. He was then asked to examine the roentgenograms and state whether or not, in his opinion, the location of the impaction could be determined therefrom with a certainty sufficient to permit the proper performance of an extraction. The trial court sustained an objection to the question, and on appeal its ruling was affirmed by the Court of Appeals of Kentucky. In malpractice actions against dentists, said the Court of Appeals, experts skilled in the dental profession are the only witnesses qualified to testify as to whether or not there was negligence in a particular method of treatment. The testimony indicated that the witness was neither an expert skilled in the dental profession nor otherwise qualified to render an opinion as to whether or not the roentgenograms indicated the impaction with sufficient certainty to allow the extraction to be properly performed. Although the witness was a physician, he had had no such experience as would qualify him to testify as an expert with respect to the matter submitted to him.—*Rawleigh v. Donoho (Ky.), 38 S. W. (2d) 227.*

Current Medical Literature

AMERICAN

The Association library lends periodicals to Fellows of the Association and to individual subscribers to THE JOURNAL in continental United States and Canada for a period of three days. Issues of periodicals are kept on file for a period of five years only. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 12 cents if two periodicals are requested). Periodicals published by the American Medical Association are not available for lending, but may be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

American Journal of Clinical Pathology, Baltimore

2: 1-72 (Jan.) 1932

Relations and Functions of Clinical Pathologist in Hospital Staff. D. Riesman, Philadelphia.—p. 1.
*Prophylactic Vaccination Against Tularemia. L. Foshay, Cincinnati.—p. 7.
*Experimental Production of Agranulocytosis. R. R. Kracke, Emory University, Ga.—p. 11.
Simple Medium for Isolation of Bacteria of Typhoid and Dysentery Groups. J. C. Small and W. A. Kreidler, Philadelphia—p 31.
*Precipitin Test for Diagnosis of Meningitis. W. A. Kreidler and Margaret E. Murphy, Philadelphia.—p. 33.
Analysis of One Thousand Five Hundred and Thirty-Five Autopsies. O. A. Brines, Detroit.—p. 37.
*Focal Cyclic Growth as Factor in Production of Nodular Goiter. B. Markowitz, Bloomington, Ill.—p. 57.
Modified Silver Stain for Treponema Pallidum. Elena de Galantha, Rochester, Minn.—p. 63.

Prophylactic Vaccination Against Tularemia.—Foshay discusses his experience with prophylactic vaccination against tularemia and describes a method for making an adequate, relatively nontoxic antigen. He believes that prophylactic vaccination will effectively protect man against laboratory infections of tularemia.

Experimental Production of Agranulocytosis.—Kracke states that agranulocytosis is a clinical entity whose pathology is probably primary in the bone marrow, followed by sepsis, which may be either local or general, or followed by no evidence of sepsis. He describes experiments in which he noted that subcutaneous injections of benzene and olive oil (if given in sufficiently small doses, so as not to affect the erythroblastic tissues) resulted in the development of clinical agranulocytosis in rabbits. The smaller the dose, the more selective became the affinity for the myelocytic tissues. The course of the condition seemed to be similar to that seen in human beings; that is, first a neutropenia, then generalized infection from organisms already present, or from organisms introduced. Agranulocytosis with subsequent infection and without infection was produced by the subcutaneous injection of benzene without olive oil and also by the intraperitoneal injection of benzene. Benzene inhalations failed to depress the leukocyte count. The intravenous injection of benzene even in small doses resulted in the immediate death of the animal, so it is probable that oxidation products of benzene are directly responsible for its leukocyte depressing properties. Agranulocytosis can be produced with benzene in a rabbit having a leukocytosis. The author believes that, although the etiology of granulocytosis is unknown, the benzene ring must be strongly considered. He recommends that those who have the opportunity to study this disease direct their attention to a careful history of possible contact with substances producing granulopenia, bearing in mind that when the patient consults the physician he presents the terminal stage of a disease that possibly began months before.

Precipitin Test for Diagnosis of Meningitis.—Kreidler and Murphy describe a rapid and accurate precipitin test for use in the diagnosis of meningitis. The precipitin test on meningitic spinal fluids renders possible the reporting of the causative organism and also the commercial serum most suitable for treatment within thirty minutes after the specimen reaches the laboratory. The authors have checked the precipitin tests with agglutination tests whenever possible and results have agreed consistently. In five cases studied in which the cultures were negative, thus rendering an agglutination test impossible, the precipitin test was positive. This fact and the possibility of returning an almost immediate report are advantages of the precipitin test in the diagnosis of meningitis that justify its use in the routine examination of spinal fluid in cases of suspected meningitis.

Cyclic Growth in Nodular Goiter.—According to Markowitz, there are two distinct processes in the physiology of the thyroid which produce a constant hyperplasia-involution cycle; namely, (1) process of thyroid secretion—active with hyperplasia, and (2) process of accumulation of colloid—passive with involution. These two processes occur as functional cycles and when in disproportion produce nodulation. In diffuse hyperplastic or exophthalmic goiter, the process of secretion overwhelms the process of colloid storage. Finally, late in the disease, this colloid storage replaces the secretion at focal points with production of nodules. In nodular colloid goiter the process of colloid storage overwhelms the process of secretion. But at focal points the secretory phase continues and is not replaced by colloid storage with production of nodules. In nodular hyperplastic goiter there is overgrowth of both processes, with colloid storage replacing thyroid secretion at focal points early in the disease with production of nodules.

American Journal of Ophthalmology, St. Louis

15: *1-94 (Jan.) 1932*

*Elective Localization in Determining Etiology of Chronic Uveitis. E. C. Rosenow and A. C. Nickel, Rochester, Minn.—p. 1.
*Considerations Underlying Experimental Production of Uveitis. A. L. Brown, Cincinnati.—p. 19.
*Study of Syphilis in Etiology of Uveitis. P. A. O'Leary, Rochester, Minn.—p. 24.
Infections of Upper Respiratory Tract in Etiology of Uveitis. J. E. MacKenty, New York.—p. 27.
New Diagram for Testing Binocular Diplopia. R. Castroviejo, Chicago.—p. 33.
Epinephrine in Progressive Myopia: III. Phase of Pupillary Reaction. L. L. Mayer, Chicago.—p. 35.
Progress in Medical and Surgical Treatment in Ophthalmology. W F. Hardy, St. Louis.—p. 37.

Elective Localization in Chronic Uveitis.—In many cases streptococci having elective localizing power have been isolated by Rosenow and Nickel in uveitis, especially in the acute form. Different foci have been found. The most frequent were teeth, tonsils, prostate or cervix. Removal of these foci, and treatment with autogenous vaccines prepared from the involved eyes of rabbits that had received injections, have been generally efficacious.

Experimental Production of Uveitis.—Brown calls attention to the difference between producing, experimentally, isolated inflammations of the uveal tract and recurring uveitis. The literature on the subject is briefly reviewed. Several series of experiments are reported in which eyes were sensitized by injecting various antigens into the anterior tissues of the eye and attacks of uveitis were produced on introducing the same antigen into other parts of the animal several days later.

Syphilis in Etiology of Uveitis.—O'Leary presents data which indicate that 6 per cent of patients with uveitis have syphilis, that treatment for syphilis brings about material improvement in the uveitis in 33 per cent, and that it affords slight benefit in an additional 28 per cent. The patients with the anterior type of uveitis as a rule respond more favorably. Deductions as to the part syphilis plays in the production of uveitis, based on the therapeutic effect, are hazardous, not only because of the fact that ocular syphilis is notoriously resistant to treatment but because nonspecific benefit was derived in 42 per cent of a group of patients who had uveitis but did not have syphilis. The incidence of syphilis among patients who have uveitis compares favorably with the general incidence of syphilis in the Mayo Clinic. Evidence was not found in the literature that *Spirochaeta pallida* is the cause of uveitis in the same sense that it is the cause of interstitial keratitis. There are, however, numerous references to syphilis as an etiologic factor in uveitis. It appears that in a small percentage of cases the etiology of uveitis is syphilis, and that antisyphilitic treatment is of benefit in 61 per cent of these cases of syphilis. In 42 per cent of the cases in which syphilis is not a factor, antisyphilitic remedies are of definite benefit also.

American Journal of Physical Therapy, Chicago

8: 261-288 (Jan.) 1932

Functional Neuroglandular Radiotherapy, Especially of Region of Suprarenal Capsules. R. Desplats, Lille, France.—p. 267.
Technic of Diathermic Epilation. H. Bordier, Lyons, France.—p. 273.

Mechanism of Ovulation in Rabbit: V. Effect of Direct Intrafollicular Injections of Extracts of Urine of Pregnancy. M. H. Friedman, Philadelphia.—p. 332.
Electrical Resistance Changes in Dying Voluntary Muscle of Rabbits. A. Hemingway and D. A. Collins, Minneapolis.—p. 338.
*Nonessentiality of Posterior Hypophysis in Parturition. P. E. Smith, New York.—p. 345.
Comparative Sensitivity of Reproductive Tracts of Hypophysectomized and Ovariectomized Rats to Follicular Hormone. P. E. Smith, New York.—p. 349.
Quantitative Study Relating Magnitude of Pulmonary Ventilation to Impairment of Oxidations Produced by Intravenous Injection of Acid and Sodium Cyanide. Marie Pelecovich, Ann Arbor, Mich.—p. 357.
*An Accessory Regulation of Acid-Base Equilibrium and Pulmonary Ventilation by Virtue of Lactic Acid Changes in Liver. G. S. McClure, Ann Arbor, Mich.—p. 365.
Late Effects of Section of Vagus Nerves on Gastric Acidity. Frances R. Vanzant, Rochester, Minn.—p. 375.
Influence of Diet and Anterior Pituitary Growth Hormone on Growth Rate of Adolescent Rats. A. H. Bryan and D. W. Gaiser, Boston.—p. 379.
Blood Regeneration Studies: II. Observations on Blood of Normal Dogs with Especial Reference to Measurement of Volume, Erythrocytes, Leukocytes and Nitrogenous Constituents. Jane M. Leichsenring, Alice Biester, Hortense H. Hönig, Sparkle M. Furnas, Edith S. Foss and M. Virginia Routt, Minneapolis.—p. 391.
Studies on Conditions of Activity in Endocrine Organs: XXVIII. Some Effects of Sympathin on Nictitating Membrane. A. Rosenblueth and W. B. Cannon, Boston.—p. 398.
Glycolysis and Oxidation of Sugar in Blood, Incubated and Circulating "in Vitro." E. W. H. Cruickshank and C. W. Startup, Halifax, N. S.—p. 408.
Hypertrophy of Gastro-Intestinal Tract and High Residue Diets. T. Addis, San Francisco.—p. 417.
Sedimentation of Erythrocytes Suspended in Lymph. J. Russell and T. E. Boyd, Chicago.—p. 424.
Rate of Disappearance of Glycogen During Contraction of Perfused Heart of Rabbit. W. E. MacPherson, H. E. Essex and F. C. Mann, Rochester, Minn.—p. 429.
*Some Chemical Effects from Constant Intravenous Epinephrine Injection in Dogs. P. C. Samson and H. R. D. Jacobs, with assistance of Hulda Rohde, Chicago.—p. 433.
Effect of Sympathectomy on Sexual Functions, Lactation and Maternal Behavior of Albino Rat. Z. M. Bacq, Boston.—p. 444.
Increased Metabolism of Sartorius Muscle of Frog Following Exposure to Roentgen Radiation. W. O. Fenn and W. B. Latchford, Rochester, N. Y.—p. 454.
Variations in Blood of Rabbits from Birth to Maturity. M. M. Kunde, M. F. Green, E. Changnon and E. Clark, Chicago.—p. 463.
*Blood Changes in Experimental Hypothyroidism and Hyperthyroidism (Rabbit). Margarete M. Kunde, M. F. Green and G. Burns, Chicago.—p. 469.
Testicular Degeneration Due to Inadequate Vitamin A in Cases Where E is Adequate. H. M. Evans, San Francisco.—p. 477.
Studies in Physiology of Exercise: VIII. Chronic Effects of Running and Swimming on Hearts of Growing Dogs as Revealed by Roentgenography. A. H. Steinhaus, J. P. Kirmiz and K. Lauritsen, Chicago.—p. 487.
Id.: IX. Chronic Effects of Running and Swimming Exercise on Hearts of Growing Dogs as Determined Electrocardiographically. A. H. Steinhaus, R. W. Boyle and T. A. Jenkins, Chicago.—p. 503.
Id.: X. Effects of Running and Swimming on Organ Weights of Growing Dogs. A. H. Steinhaus, Loris A. Hoyt and H. A. Rice, Chicago.—p. 512.

Posterior Hypophysis Not Essential in Parturition.—Smith removed the posterior hypophysis in adult female rats and noted the effect on parturition. The completeness of the ablation was verified by a microscopic examination of serial sections of the pituitary capsule and its contents. In all cases some anterior lobe tissue also was removed, but a sufficient amount remained to maintain normal body growth and sex cycles. Six of these animals were mated and bore litters. Birth occurred at the usual time. The evidence thus shows that in rats a secretion of the posterior hypophysis is unnecessary either for the genesis or for the maintenance of the uterine contractions at parturition.

Liver, Lactic Acid and Acid-Base Equilibrium.—McClure reports the results of a study of the function of the liver in the control of the acid-base equilibrium. The assumption that absorption and reconversion of lactic acid by the liver to glycogen or sugar is accompanied by a liberation of free base and a reduction in hydrogen ion concentration was tested by p_H determinations of portal, arterial and hepatic venous blood. The assumption that the magnitude of this reconversion of blood lactic acid and liberation of free base would vary with the degree of impairment of oxidation and concentration of blood lactic acid was tested by similar p_H determinations following intravenous injection of sodium cyanide. Under the basal conditions obtaining the hydrogen ion concentration was lowest in the hepatic venous blood, highest in the portal blood and midway between in the arterial blood. Intravenous injection of sodium cyanide produced variable effects on the hydrogen ion concentration of the arterial blood, depending on the accompanying changes in pulmonary ventilation. The greater the augmentation of ventilation, the greater was the initial decrease in hydrogen ion concentration. Intravenous injection of sodium cyanide produced a large increase in the hydrogen ion concentration of the portal blood and a relatively small increase in the hepatic venous blood. The resulting increase in the difference of hydrogen ion concentration between portal and hepatic venous blood occurred with and without an accompanying decrease in hydrogen ion concentration of the arterial blood. The fact that hepatic venous blood showed a lower hydrogen ion concentration than the portal or arterial blood during "normal basal conditions" suggested that the liver is continually removing lactic acid from the blood and liberating free base. The fact that the difference in hydrogen ion concentration between portal and hepatic venous blood increased after intravenous injection suggested that this process is augmented during impaired oxidation. The liver thus provides a self-corrective mechanism against acidosis arising from impaired oxidation. The resupply of sugar to the blood and tissues resulting from the reconversion of lactic acid is considered as an accessory mechanism supporting the failing oxidations. Assuming a reconversion of 28 mg. of lactic acid per hundred cubic centimeters of blood, enough base is liberated to lower the hydrogen ion concentration of the portal blood about 0.09 p_H. This approximates the difference in p_H of portal and hepatic venous blood of the "normal basal condition" found in these experiments. Assuming that the flow of blood through the liver equals 20, 30 or 40 per cent of the total cardiac output, it is computed that the continuous effect of the liver on the hydrogen ion concentration of the total mixed blood should be approximately a reduction of 0.018, 0.027 or 0.036 p_H with each complete circulation of the blood.

Constant Intravenous Epinephrine Injection in Dogs.—Samson and Jacobs administered epinephrine intravenously to unanesthetized dogs at constant rates over relatively long periods of time (up to thirteen days). Continuous epinephrine administration resulted in a transient hyperglycemia and glycosuria, both of which disappeared in twenty-four hours. The normal glycemia persisted with continued injection, even when the rate of administration was doubled, and there was no further glycosuria. The cessation of epinephrine administration while the blood sugar values were within normal limits led to an abrupt hypoglycemia with a slower return of the blood sugar to normal values. With further injection a second hyperglycemia and glycosuria occurred, although not as marked as the first. Continuous epinephrine administration increased the urinary output in every case. Continuous epinephrine injection did not affect the urinary nitrogen excretion as measured by twenty-four hour periods. Comment is made on the possibility of interpreting the glycemic curves.

Blood Changes in Hypothyroidism and Hyperthyroidism.—According to Kunde and her associates, the anemia of hypothyroidism (rabbit) is characterized by a greater than normal diameter of the erythrocytes, a color index greater than 1, a normal hydrochloric acid content of the gastric contents, and a bone marrow which does not simulate either grossly or microscopically the bone marrow of pernicious anemia. The cholesterol content of the blood, accompanying the anemia of hypothyroidism, is greater than normal. Experimental hyperthyroidism in the rabbit causes an initial polycythemia and a corresponding increase in hemoglobin. Prolonged hyperthyroidism results in an anemia characterized by a color index less than 1 and a decreased diameter of the red blood cell. The total blood volume in experimental hypothyroidism and hyperthyroidism (dye method) does not change beyond the limits of normal variation. In the normal adult rabbit, desiccated thyroids in dosages of from 250 to 450 mg. daily per rabbit does not cause an appreciable increase in the percentage of reticulocytes. In the cretin a reticulocyte response varying from 4 to 10 per cent occurs as the result of thyroid feeding.

*Cyst of Pancreas Associated with Ectopic Splenic Island. C. A. Traver, Albany, N. Y.—p. 127.

Skull Fracture Involving Frontal Sinus.—Gurdjian and Shawan report that the incidence of frontal sinus fractures in a series of more than 2,600 cases of skull fracture was around 5 per cent. The majority of sinus fracture cases are asymptomatic. The patients should be confined to bed for a period of eight to ten days at least. They should not be permitted to blow the nose. Intranasal douches are contraindicated. The patient should be watched for infection in the sinus and suppuration within the cranial cavity. Compound fractures in this situation should be operated on as soon as the condition of the patient permits. The posterior wall of the sinus should be inspected. The great majority of frontal sinus fractures should be left alone. The results with conservative treatment are gratifying. The incidence of meningitis in the authors' series was 0.8 per cent.

Roentgen Visualization of Parotid Gland.—Barsky and Silberman emphasize the fact that roentgen examination of the parotid gland after injection of iodized poppy-seed oil 40 per cent is a simple, safe procedure when properly performed. In their series no injurious effects have resulted from the injection. Injection of the gland with iodized poppy-seed oil should never be made in the presence of active infection. At present, this method is the only accurate way of determining the exact condition of the gland and its deviations from the normal when diseased. In cases of parotid fistula, actual visualization of the ducts is of the greatest aid in determining the course of treatment.

Primary Tuberculosis of Parotid Gland.—According to Berman and Fein, tuberculosis of the parotid gland is rare and is often mistaken for malignant tumor or syphilis. Two distinct types are usually found: The first is the chronic or fibroid type, which is encapsulated and may not produce symptoms for months or even years; the second type is acute inflammatory, which is diffuse and runs its course in a few days or a week. Tubercle bacilli gain entrance into the parotid gland by one of three ways, canalicular, hematogenous or lymphatic, with the first being the most common. Symptoms consist of swelling of the gland, as either a circumscribed or fluctuating tumor, or more diffuse with an occasional soft spot. The second is usually adherent, red, tense, shiny and edematous. Pain is a late sign and the lymph nodes of the neck are not involved. Diagnosis is likely to be difficult unless it is confirmed by biopsy. Prognosis is good, as the condition is purely local. The treatment is purely operative, and even when facial paralysis takes place from injury to the facial nerve, either by disease or by operative trauma, there is recovery in most instances.

Abscess of Spinal Cord.—In a review of fourteen cases of metastatic epidural abscess of which the histories are recorded in the literature, Craig and Doyle discovered only one in which the patient had recovered. They report an additional case in which the condition was diagnosed, the patient operated on, and recovery took place.

Pulmonary Embolism and Infarction.—Hosoi's study is based on sixty-four verified cases of pulmonary embolism with or without infarction. They consist of twenty-five postoperative, three posttraumatic, and thirty-six medical cases of embolism. This gives a necropsy incidence for embolism of 7.9 per cent, a mortality incidence of 2.1 per cent, and a morbidity incidence of 0.102 per cent. Sex has probably no etiologic significance. The age incidence of embolic cases suddenly increases from 40 years onward. The obese patients with embolism were all in this age liability group. Embolism occurred in 0.09 per cent of the patients after general surgery and in 0.08 per cent after gynecologic surgery. Sixty-four per cent of the cases occurred in the first and second weeks postoperatively. The duration of symptoms from onset of pulmonary embolism to death varied from sudden to ten days, 80 per cent dying by the third day. Sixty-eight per cent of the operations were in the lower part of the abdomen. On the other hand, in medical embolism, the duration of symptoms was longer (as long as twenty-seven days) owing to the greater frequency of smaller emboli occurring sometimes in showers. Furthermore, patients with medical embolism were not so severely affected, since only about one third of them died within the first three days. Forty-two per cent of the postoperative emboli lodged in the lower lobes, more often on the right in the ratio of almost 2:1, and 42 per cent in the main pulmonary artery or in one or both of its two branches, the right being favored. Owing to the frequency of the embolism being less massive in medical cases, the emboli were able to reach the smaller branches of the pulmonary artery; in 64 per cent of the cases the lower lobes were involved, but, contrary to postoperative infarction, medical infarction occurred more often in the left lower lobe than in the right lower. There was manifest infection in only 32 per cent of the postoperative cases and in 50 per cent of the medical cases. Infarction after embolism is liable to occur when there is an added circulatory congestive disturbance. The pathologic changes in the heart presented a varied picture of hypertrophy, cardiosclerosis and endocarditis. The hearts in the medical cases were uniformly larger and 42 per cent of them showed severe lesions of hypertrophy and dilatation (decompensation), coronary thrombosis with infarction, vegetative endocarditis, and pancarditis. Infarction occurred almost twice as frequently after medical embolism as after postoperative embolism.

Closing Bronchial Stump in Pulmonary Surgery.—Adams and Livingstone describe experiments on dogs in which they demonstrated that complete stenosis of a bronchus one-half inch in diameter was the usual occurrence in two weeks following the application of a 35 per cent solution of silver nitrate. Stenosis of the bronchial lumen was brought about by collapse of its wall and by filling in of the lumen with the injured elements of the wall and granulations, with subsequent fibrous tissue formation. Massive atelectasis accompanied complete stenosis of the main bronchus of a pulmonary lobe. No atelectasis was present when all the main air passages to the lobe were not completely obstructed. The entire wall of a bronchus became necrotic following cauterization with a 75 per cent solution of silver nitrate. Parts of the wall remained viable when solutions of a lower percentage were used. The cartilages and elastic tissue were found to be the most resistant to destruction by the solutions employed. Following necrosis of the entire bronchial wall, only the epithelium was found to regenerate. Regeneration of the epithelium was rapid, not infrequently giving rise to polypus and inclusion cyst formation. Fibroblastic proliferation was pronounced, especially following 35 and 50 per cent solutions of the chemical.

Rupture of Hydronephrotic Kidney.—Lazarus states that the incidence of rupture of congenital hydronephrotic kidneys is small. In children, kidneys that rupture as a result of mild traumas are usually hydronephrotic. So-called spontaneous rupture of kidneys may be due to mild forms of trauma easily overlooked by patients. They are rare, as attested by a paucity of cases reported in the literature. Hematuria is not a cardinal symptom in rupture of the kidney. The presence of ecchymotic areas over the skin of the loin, thigh, penis or perineum may be suggestive of a renal injury. Exploratory laparotomy is indicated in all cases in which doubt exists regarding the presence of an intra-abdominal lesion associated with the renal injury. The kidney should be exposed and explored through a second incision in the loin. Retroperitoneal extravasations are best drained through the lumbar route rather than transperitoneally. Conservative surgery cannot be employed in cases of ruptured congenital hydronephrotic kidneys, nephrectomy being the procedure of choice.

Cyst of Pancreas.—Traver reports a case of cyst of the pancreas in a man, aged 61, who died of pulmonary embolism twenty-one days after operation. The cyst had ruptured, the contents causing widespread fat necrosis. The lining of the cyst suggested an origin from pancreatic ducts, with possibly a congenital anomaly of the ducts as a basis for the condition. This hypothesis is supported by the presence of another anomaly, splenic tissue within the pancreas. Other theories of etiology are discussed. Treatment consists of early operation with prolonged drainage. Complications are frequent.

Progressive Pallidal Degeneration.—Winkelman describes two cases with an unusual syndrome occurring in brothers, in one of whom a pathologic study of the nervous system was made. For this syndrome he suggests the name progressive pallidal degeneration. It consists of a progressive rigidity, which begins in the lower limbs and eventually involves the entire body. In the author's patients, retinitis pigmentosa was present as evidence of a familial condition. Pathologically, the same sort of involvement was present in the pallidum and in the reticular portion of the substantia nigra. One case in which a pathologic study was made further advances the idea that the pallidum and reticular portion of the substantia nigra are phylogenetically and ontogenetically similar. The name "pallidal system" is suggested for these two structures. The author believes that rigidity without tremor may be the only clinical manifestation of involvement of the pallidal system.

Cranial Sensory Nerves.—Dandy believes that paroxysmal pain of the type observed in the trigeminal and glossopharyngeal nerves is just as positive evidence of origin in a higher sensory level as a clonic convulsion is evidence of origin in a higher motor level. And just as one cannot produce a clonic convulsion by a lesion on or stimulation of a peripheral motor nerve, so one cannot produce a paroxysmal pain by a lesion of a peripheral sensory nerve. A chance observation on a sensory cranial nerve appears to lend support to, and perhaps to amplify, these conclusions. During an operation on a hypophyseal tumor, the right optic nerve was accidentally divided through somewhat more than half of its transverse extent when the line of vision was momentarily obscured by the handle of a curet. The cut in the nerve was oblique and extended anteriorly and outwardly for a distance of about 1 cm. from a point on the inner side of the nerve, about 2 mm. anterior to the chiasm. Anteriorly, the cut extended somewhat beyond the midline of the nerve. Prior to operation, the patient had shown a bitemporal hemianopia for form and color in each eye. The visual acuity was slightly less on the side of the operation (right). Forty-eight hours after the operation the fields of both eyes had in large part returned, and before the patient left the hospital, two weeks later, repeated perimetric tests by different examiners gave normal fields for form and color in both eyes, and the visual acuity was normal. There was no scotoma. Not the slightest defect of vision could be detected in the affected eye at any time. To test the results as far as possible, an experiment was made on a dog as follows: The outer half of the left and the inner half of the right optic nerves were sectioned immediately in front of the chiasm. Several days after the operation, the dog was tested by rapid movement through a narrow irregular path. Although a right homonymous hemianopia would have been the expected result of the experiment, the dog rapidly negotiated the path through the laterally placed impediments on either side with perfect ease. Although the animal was tested repeatedly, there was no tendency to run into objects on the side on which blindness might have been expected. Although the result in this canine experiment apparently harmonizes with the negative human result, there still remains a doubt, because the dog may be able to compensate for loss of vision by rapidly shifting the eyes and neck. When a rough test of the fields of vision was made by thrusting an object toward the eye, vision seemed to be unaffected; but in this respect again the test is too crude to be dependable. As a matter of fact, the negative results of hemisection of the optic nerve are almost precisely similar to those attending hemisection of the trigeminal nerve. The author realizes that these results, if correct, are difficult if not impossible to harmonize with an inflexible neuron doctrine.

Osteitis Fibrosa Cystica of Skull.—Palmer and his associates report a case of localized osteitis fibrosa cystica resulting from an injury to the skull in infancy and giving rise to neurologic symptoms twelve years after the occurrence of the trauma. The etiologic rôle of the trauma is significant since recent literature has tended to designate the generalized form as dependent on parathyroid hyperplasia and the local type as determined purely by trauma. Yet it is obviously rare that bone injury alone leads to the formation of cystic areas of osteitis. In the light of recently established relationship between endocrine imbalance and the malacias, it may be conjectured that there are conditioning endocrine factors in patients who develop cystic bone lesions following a trauma, resulting in a disordered metabolism and predisposing to anomalous repair with typical cyst formation. Focal compression of the right occipital pole by the intrusion of the inner wall of the bone cyst produced a lesion of the calcarine cortex, evidenced by the incomplete left homonymous hemianopia. Irritation of the visual cortex in this area occasioned visual hallucinatory phenomena. The similarity between the picture presented by the authors' patient and that of patients with tumors of the occipital lobe is worthy of emphasis. The differential diagnosis rested largely on the roentgenologic observations.

Peripheral Nerves.—According to Hassin, the structure of a peripheral nerve fiber is more complex than that of a central fiber. The Schwann cells and the Schwann membrane form one structure. The Schwann membrane separates the parenchyma from the surrounding mesodermal tissues. The Schwann cells undergo irreparable changes in wallerian degeneration and are, like the damaged parenchyma, removed from the place of the lesion. As such cells cease to exist, new nerve fibers cannot be produced from them, as has been maintained by the antineuronists. The Schwann cells seen in a peripheral sector evidently come from the central stump and accompany the outgrowing new fibers. The endoneural cells growing in both central and peripheral stumps merge to form cell cordons, which constitute the proper conducting pathways for the outgrowing nerve fibers. Such cordons not only assure proper pathways for the growing nerve fibers but assist in their metabolism by removing the products of the latter. The absence of such syncytial structures in the brain is probably the cause of the failure of central fibers to regenerate.

Polyneuritis with Facial Diplegia.—Taylor and McDonald report sixteen cases of polyneuritis, fourteen with facial diplegia, one without definite facial paresis and one of double facial involvement and paresis of other cranial nerves without involvement of the extremities. From a study of these and other cases reported, it is evident that the syndrome is of relatively frequent occurrence, that it is sporadic and never appears in epidemic form, and that it is not confined to adult life. The etiology has not been definitely determined. The signs of infection are slight and often entirely absent. A febrile onset is inconstant. No fixed latency period, therefore, can be determined. The symptomatology, apart from the somewhat arbitrary coincidence of facial diplegia and general peripheral neuritis or neuronitis, is varied. No constant relationship exists between the appearance of the facial paresis and the more general signs of neuritis. The duration of the disease is from one or two weeks to several months. Death, from respiratory involvement, is rare. Complete recovery is the usual outcome. Occasionally, full facial control does not return. Pathologic changes are of the nature of a diffuse inflammation, involving especially peripheral neurons, the cord and brain stem to a lesser extent and the cortex slightly if at all. The cerebrospinal fluid varies from normal to a condition characterized by a pronounced increase in total protein with slight or often no increase in the number of cells (albuminocellular dissociation—Guillain).

Convulsions of Dementia Paralytica.—Merritt presents evidence showing that sclerosis of the cornu ammonis is of vascular origin. He reports thirty cases of dementia paralytica with sclerosis of the cornu ammonis; the incidence of epileptiform phenomena was found to be 90 per cent. No evidence of an organic vascular occlusion was found in these cases, and there was no apparent causal relation between the sclerosis and the inflammatory reaction around blood vessels.

Coronary Thrombosis.—Meakins and Eakin state that the treatment of coronary thrombosis is the same as that of thrombosis elsewhere. An essential feature is the allowance of time not only that adaptation to the injury may be acquired but also that anastomosis may take place. Therefore, rest is of the greatest importance. This is rather difficult at times to insist on, as the acute symptoms of coronary occlusion comparatively rapidly disappear, and the patient cannot understand why a prolonged period of absolute bed-rest is insisted on. A firm attitude and judicious instillation of fear is therefore strongly indicated. The use of digitalis is at first to be recommended but seldom. As time passes and symptoms of circulatory failure develop, it is then indicated. In the rare case of ventricular tachycardia, quinidine would be indicated; otherwise medication, apart from the use of morphine during the acute attack, would logically have but little value. The most difficult period of the treatment comes when the patient is allowed more liberty and activity. It is impossible to lay down hard and fast rules governing this. It is a question of individual cautious trial and experiment. The easy production of dyspnea and fatigue are contraindications for liberty. If the patient is intelligent, much can be done with his cooperation. When signs of congestive circulatory failure develop, the cases must be handled in exactly the same manner as when they are due to other causes. The occurrence of repeated thrombosis must always be borne in mind and must govern one not only in the prognosis but also in the treatment.

Angina Pectoris in Anemia.—According to Gwyn, the results of treatment in cases of "anemic angina" would seem to indicate that the anemia plays at least an important part in the production of the cardiac symptoms. Transfusion has apparently cured several patients almost at once, and it would seem that by the building up of the blood condition a severe angina may disappear. Whether one should conclude from this that one can close one's eyes to the possibility of coexisting coronary disease is of course another question. By relieving the anemia one has, of course, lessened considerably the degree of anoxemia, and if the anemia has been permanently done away with, a heart might well carry on even with partially obstructed coronaries. Any aid that might be expected from the development of a collateral circulation has probably been discounted by the time the patient appears before the physician.

Cholesterol Metabolism.—McEachern and Gilmour find wide variations in the five-hour blood cholesterol curve in twenty-eight normal fasting persons. Such variations render single or haphazard studies of blood cholesterol of doubtful value. There was no evidence of cholesterol absorption or effect on the blood level in twelve normal persons given large doses of this substance.

Leukorrhea.—Conn emphasizes the fact that up to the present not much attention has been paid to the monilia or yeast fungus as a cause of leukorrhea. The yeast fungus may be present without causing any symptoms. As a rule it does not cause much discharge, but the reaction of the vagina is usually highly acid. This infection may also be present in pregnant women. Parous women are more often infected than nulliparas. The symptoms caused are itching, burning and smarting of the lower vulva and vagina. Digital examination, speculum examination, and sexual intercourse may be painful. The organism may be found by the ordinary examination under the microscope, or one may stain it. It may also be grown in culture. The treatment recommended by the author is 1 per cent gentian violet in aqueous solution. Alkaline douches are also advised.

Acute Appendicitis.—McKenty presents a study of 401 consecutive cases of acute appendicitis showing satisfactory results in the uncomplicated cases and in the cases with localized peritonitis and abscesses, and unsatisfactory results in 57 cases of diffuse peritonitis. A review of reports published since 1920, covering 17,916 cases, shows that among British and American surgeons the average mortality is 6 per cent and that 60 per cent of the total deaths are due to diffuse peritonitis. Immediate operation in diffuse peritonitis of appendical origin has a mortality of 31.9 per cent. The author believes that whether the results under the Ochsner-Sherren plan of treatment are better or worse cannot be ascertained from a study of the literature. The followers of this plan have not published statistics which would enable the profession to judge of its merits.

Irradiated Ergosterol: I.—Bauer and his associates describe experiments in which they noted that the administration of viosterol in small doses to normal individuals produced no constant changes in either the calcium or the phosphorus metabolism. The administration of viosterol in daily doses of 30 mg. to normal individuals resulted in an immediate increase of the fecal calcium and phosphorus excretion. The urinary calcium and urinary phosphorus were decreased. Following this there occurred a decreased fecal calcium and phosphorus excretion and an increase in the urinary calcium and phophorus excretion. The calcium and phosphorus balances were only slightly affected. Following the cessation of viosterol administration, the fecal calcium and phosphorus promptly rose and the urinary calcium and phosphorus fell slightly. The serum calcium and phosphorus of normal individuals was only slightly affected by viosterol therapy. The nitrogen excretion was unaffected by viosterol administration. No constant changes in the blood plasma cholesterol were noted during the administration of viosterol. No untoward symptoms resulted from the administration of as much as 30 mg. of viosterol a day.

Irradiated Ergosterol: II.—Bauer and Marble report that a case of osteoporosis was greatly improved by the administration of viosterol in conjunction with a high calcium diet. A case of osteomalacia with tetany secondary to faulty absorption showed immediate and lasting benefit from viosterol. Viosterol acts as a specific drug in this type of calcium phosphate disorder. No untoward symptoms were observed in either case as the result of such therapy. The action of viosterol is the same in normal individuals as in individuals with calcium deficiency diseases; namely, to increase absorption of calcium and phosphorus from the gastro-intestinal tract. If there exists a calcium phosphate deficiency of the serum as well as the bones, the additional calcium and phosphorus absorbed is retained in order to establish a normal relationship of calcium and phosphorus in the serum and thus allow the deposition of calcium phosphate in the bones. In calcium deficiency diseases in which there is a calcium phosphate deficiency of the bones only, the consequent retention is not so marked, whereas in normal individuals little or no retention takes place because the serum and bones are both normal in respect to calcium phosphate. The dose of viosterol necessary to produce such changes in the calcium and phosphorus metabolism of individuals with calcium deficiency diseases is much smaller than the amount required to produce changes in the calcium and phosphorus metabolism of normal individuals.

Irradiated Ergosterol: III.—The administration by Bauer and Marble of a high calcium diet to cats with calcium phosphate deficiency of the bones resulted in an increase in the number of bone trabeculae. This increase in the number of bone trabeculae was greater when, in addition to a high calcium diet, viosterol was given.

Normal Gastric Acidity.—In a series of gastric analyses of 200 normal patients, using histamine and alcohol as the gastric secretory stimulants, Lerman and his associates found that the average free acidity was 40.4 cc. of tenth normal acid and the average total acidity 50.1 cc. There was no correlation between age and gastric acidity. The incidence of anacidity was 13 per cent. Up to the age of 65 there was a definite correlation between age and the incidence of anacidity. Beyond this age the number of cases with anacidity dropped off and the number with hyperacidity increased. The average gastric acidity was higher in the male than in the female. Consequently females more frequently show anacidity and hypo-acidity and less often hyperacidity. The red blood cell count and hemoglobin content tended to vary directly with the level of gastric acidity. Consequently the greater the tendency to achlorhydria, the lower the red blood cell count and hemoglobin content; the greater the tendency to hyperchlorhydria, the higher the red blood cell count and hemoglobin content. From the data available in forty-one cases it seemed that there was some degree of correlation between the incidence of gastric anacidity and level of basal metabolism.

Gastric Secretion in Thyroid Disease.—Lerman and Means state that in patients with exophthalmic goiter and myxedema there is a definite lowering of the gastric acidity to about half its normal value. The incidence of achlorhydria in exophthalmic goiter is 38 per cent and in myxedema is 53 per cent. Corrected for the age distribution of a normal group, the incidence is 46 per cent and 75 per cent, respectively. The frequency of achlorhydria is out of proportion to the depression in the average acidities and suggests that other factors are also important in its causation. There is perhaps a threshold of gastric secretion, and if the secretion is depressed beyond it, anacidity results. In exophthalmic goiter there is no definite correlation between gastric acidity and such factors as age, red blood cell count, hemoglobin and level of basal metabolism. On the other hand, there is a high degree of correlation between the incidence of achlorhydria and age and basal metabolic rate and a probable inverse correlation between the incidence of achlorhydria and red blood cell count and hemoglobin. There is also a higher incidence of achlorhydria and hyperchlorhydria among males than among females. In myxedema there is an unusual tendency to anemia among patients with achlorhydria. There is indirect evidence that achlorhydria may persist in some cases at least after the primary condition has been cured. The knowledge of the gastric secretion in an individual case may be of practical importance in prevention of the development of anemia.

Syringomyelia.—Goodwin reports a case of syringomyelia in which twelve years elapsed from the time of onset before symptoms developed that were definite enough to warrant the diagnosis. He believes that when there is a history of nervous manifestations over a period of five, ten or fifteen years the possibility of syringomyelia should always be considered. The dissociation of touch and pain is almost distinctive, but this phenomenon is also sometimes found in neuritis, hysteria and tabes. Various cord levels are apt to be affected, and, as a consequence, one may have various symptom complexes. Certain degenerative lesions may be present for a considerable time without being noticed, and relatively recent and sudden symptoms should not rule out the diagnosis.

Tissue Specificity of Mycobacterium Tuberculosis.—Byles describes a case of primary renal tuberculosis, confirmed by necropsy. A guinea-pig inoculated with urine from the patient developed tuberculous lesions only in the kidneys and at the inoculation point. Two guinea-pigs inoculated with material from a kidney of the first pig also showed lesions only in the kidneys and at the inoculation points. Cultures from a kidney of one of the pigs showed growth typical of Mycobacterium tuberculosis (hominis). A guinea-pig inoculated with a bacterial suspension from the cultures showed lesions only in the kidneys and at the inoculation point.

*Ulcer of Stomach and Duodenum. E. S. Judd, Rochester, Minn.—p. 17.

Insulin in Depancreatized Dogs.—Tuttle describes experiments in which he demonstrated that a considerable amount of dextrose oxidizes or is utilized anaerobically by the depancreatized dog. Since insulin is necessary for the oxidation of dextrose, extrapancreatic or cellular insulin must exist in the normal dog after total pancreatectomy. The amount of this insulin gradually increases under the stimulation of the high blood sugar as the experiment progresses. The reason this insulin can increase thus is that the dog was not naturally diabetic at the time of operation, so that his cellular insulin can be normally increased by carbohydrate stimulation. If he had been naturally diabetic, no such increase or one much less, in proportion to the severity of the diabetic state, would have resulted (because the mechanism for producing cellular insulin may also be deficient in many diabetic states). Muscular action uses up considerable amounts of blood sugar anaerobically without the need of the assistance of insulin; and consequently in diabetic cases in which there is a deficiency of insulin such exercise takes the place of a certain amount of insulin in keeping the blood sugar near normal.

Ulcer of Stomach and Duodenum.—Judd believes that the final word concerning gastric and duodenal ulcer has not yet been spoken. The multiplicity of hypotheses advanced to explain their origin indicates that many factors play a part, differing perhaps in each case. In the presence of conflicting views, regarding the origin of ulcer, different forms of treatment are justified only on the basis of experience. A sharp line must be drawn between gastric and duodenal ulcer. The problem of carcinoma enters into the consideration of gastric ulcer. No matter how small a percentage of gastric ulcers are malignant or will become malignant, this possibility adds to the seriousness of the disease. Carcinoma almost never occurs in the first portion of the duodenum, so that the question of malignancy need not enter into consideration in the treatment of these cases. Many duodenal ulcers heal permanently under medical treatment. Any one with a duodenal ulcer is entitled to a trial of this type of treatment and to continue with the regimen so long as it is helpful. It is not a good plan to operate when the lesion is bleeding. If the patient has had one hemorrhage only and is free from symptoms at the time of the examination, it is not necessary or advisable to operate immediately. If he has a recurrence of symptoms, an operation may be indicated. If it becomes necessary to operate, particularly because of repeated severe hemorrhages, it is imperative to remove the ulcer if it can be done thoroughly by local excision, removing part of the muscle of the pyloric sphincter. If this cannot be accomplished because of the local condition, it is advisable to resect the stomach with the ulcer if possible. The local operation of excision of ulcer, with the cap of the duodenum and a considerable part of the pyloric sphincter, completing the operation as a gastroduodenostomy, is the operation of choice in all cases of ulcer of the duodenum and in ulcers on the gastric side near the pylorus. The radical operation is preferable in cases of gastric ulcer, particularly if there is considerable associated gastritis. Gastro-enterostomy gives satisfactory results for obstructing ulcer in the duodenum of patients past middle age. There is sure to be complete relief of symptoms, with little probability of the formation of secondary ulcers. A person who has once had an ulcer must always be considered as having an ulcer potentiality. Although it is not necessary for him to hold too rigidly to dietary restrictions, he should be very cautious about his diet and activities at any suggestion of a return of his former symptoms. If he is willing to conform, there is no reason why he cannot be made comfortable and live a useful and active life; if he does not follow this plan, the recurring trouble is likely to be much more difficult to control than the original trouble.

Ear Complications in Acute Craniocerebral Injuries.—Gurdjian emphasizes the fact that aural bleeding in cases of craniocerebral injury is a serious complication. The treatment is conservative in cases both with bleeding and with cerebrospinal fluid discharge. The ear should be left alone if it has stopped bleeding. Unnecessary examination may cause the introduction of infection. In cases in which there is still some discharge, the external ear should be carefully cleansed, the wall of the external auditory canal painted with 4 per cent iodine solution, and a mastoid dressing applied either with no packing of the canal or with very loose packing. As long as the patient does not complain of earache and there are no unexplainable clinical manifestations, the less done to the patient, the better the results. A total of 476 cases of aural bleeding or cerebrospinal fluid leakage from the ear are reported by the author. The right ear was involved in 36.5 per cent of the total group, and the left ear, in 43.1 per cent; there was bilateral bleeding in 20.6 per cent of the cases. In the group examined by roentgen ray, positive observations in cases with unilateral bleeding were 93 per cent, and in cases with bilateral bleeding, 98 per cent. Otitis media was found in nine cases, meningitis in four, and mastoiditis in three. The mortality was 37.1 per cent with right-sided, 38.5 per cent with left-sided, and 67.3 per cent with bilateral discharge.

Gastric Tumors.—According to Dwyer, the roentgenologist seldom fails to diagnose a gastric cancer; yet, owing to the location of the growth and the failure to recognize early signs of the lesion, the majority of gastric cancers are far advanced at the time of diagnosis. A patient who gives a history of chronic dyspepsia and whose gastric secretions show the presence of free hydrochloric acid may have a cancer of the stomach. This patient is just as deserving of a detailed study to determine or to rule out cancer as is one who consults a physician on account of comparatively recent development of gastric symptoms. In the author's series of patients with gastric carcinoma 38 per cent gave a history of dyspepsia averaging ten years before the onset of symptoms characteristic of cancer. Seventy per cent of these patients had free hydrochloric acid in their gastric contents. The author believes that the value of careful palpation of the partially filled stomach during fluoroscopy cannot be emphasized too strongly.

Operation for Duodenal Ulcer.—Balfour calls attention to the fact that the selection of cases of duodenal ulcer for early operation would be greatly simplified if it were possible to predict with any accuracy the course of the disease in the individual case. For example, if one could know that the best of repeated medical treatments, and dietary regimen, would fail to control the symptoms of duodenal ulcer, much time, money and suffering would be spared the patient by early operation. As yet there are no satisfactory criteria on which to base predictions in the uncomplicated case. In the complicated case, that is, when the severity of symptoms or the radiation of pain indicates that extraduodenal involvement has occurred, intestinal hemorrhage, or when motor impairment can be demonstrated, early operation is clearly the best course for the patient to pursue, unless it is definitely contraindicated. In the absence of such complications, there are certain conditions under which operation may properly be advised for early uncomplicated duodenal ulcer. There are two groups of cases of uncomplicated duodenal ulcer in which early operation holds definite advantages for the patient. The first of these is represented by the patient who, in spite of conscientious effort to carry out well directed treatment, fails completely to control the symptoms. These patients are usually young, and at the most important period of their careers, and elimination of the recurring disability at such a time would be greatly to their advantage. In the second group, the patient, because of his unwillingness or inability to carry out the necessary regimen, is subjected to the recurrences of attacks which are characteristic of the disease. If such attacks are prolonged and disabling, nothing is gained by delaying surgical treatment. These two groups comprise a considerable number of duodenal ulcers, and the author is convinced that carefully applied surgical measures constitute the best method of dealing with the disease at this stage.

Carcinoma of Stomach.—According to Davis, it is highly probable that in chronic atrophic gastritis has been discovered a cause of many of the insidious cases of cancer of the stomach which have usually been spoken of as "primary" cancer. Chronic gastric ulcers offer a basis for an undetermined proportion of gastric cancers, and recognition of this fact may result in earlier operation in these cases. Therefore both ulcer prevention and ulcer cure and gastritis prevention and gastritis cure are a part of cancer prevention and cancer cure. There is already enough known about carcinoma of the stomach to make possible the cure of a much larger proportion of persons with this disease than was formerly possible.

Acute Mastoiditis.—Hitz emphasizes the fact that acute mastoiditis is always potentially a serious matter from its inception and should be promptly recognized and efficiently handled. A general physical survey should always be made including roentgen examination of temporal bones, frequent eyeground examinations, blood count, and urinalysis and, on the slightest suspicion of complication, blood cultures and spinal fluid examination. Operation when it has been decided on should be promptly done and completely executed. Half done measures are worse than useless. Secondary operations may be considered to be evidence of poor primary work and of poor judgment. They greatly add to the danger of life and prolong the period of recovery. Overlong preoperative observation also makes possible the subsequent danger to hearing, for the longer a discharge continues from a middle ear the more are inflammatory residues likely to be a disturbing element to future hearing. Properly taken roentgenograms are invaluable in determining the extent of the cellular development and often the degree and possible extent of the infected area. They should always be taken whenever and wherever the means of so doing are available.

Potency of Serum Fractions in Antivaccinal Serum.—Ledingham and his associates secured an antivaccinal serum by hyperimmunization of the horse with the virus of vaccinia. The antiviral body is associated with the euglobulin as well as with the pseudoglobulin fractions of the serum, but not with the albumin. The euglobulin fraction contains the antibody in highest concentration per gram of protein, but its absolute amount falls below that present in the pseudoglobulin fraction. In the course of hyperimmunization pursued intermittently over a period of nine months, the natural serum of the horse exhibited variations in potency, but it was established that falls in titer could be succeeded by maximal titers in response to further stimulation. The serum when administered simultaneously with the virus proved highly effective in controlling experimental infections of rabbits with strains of virus of cutaneous and testicular origin. Though therapeutic effects from late administration of serum have not been definitely elicited in the experiments adduced, it is held that success in this direction may depend largely on dose of virus, and that further experimentation on therapeutic lines is desirable, if only to secure some valid basis for its exploitation in human infections with this virus.

Serum Treatment of Anaerobic Infections.—Craddock and Parish describe experiments on mice in which they noted that Vibrion septique antitoxic serum confers complete protection against massive doses of living culture of Vibrion septique. It is also highly effective in the prophylaxis and treatment of infections produced by washed spores with calcium chloride as activator. A concentrated antitoxin, injected intravenously or intraperitoneally in divided doses, protected from 75 to 100 per cent of mice against 100 fatal doses of spore-activator mixture. Mice nearly moribund five hours after infection recovered after the intravenous administration of antitoxin. A most important indication from this research is that, when antitoxin is used therapeutically in the treatment of anaerobic infections in man, it should be given without delay in large doses by the intravenous route.

Rat Thyroids.—Drennan and his associates attempted to produce a diet adequate for normal growth in the rat, but sufficiently low in iodine to produce thyroid change. This was best achieved by a diet of white bread and fresh milk. After a period rats on this diet developed an active type of gland, low in iodine content, and large relative to the body weight. The addition of small amounts of iodine to such a diet kept the thyroids small, colloid, and with a rich iodine content. As iodine was again omitted from the diet, the thyroids tended to enlarge and assume the active type of gland similar to those in the animals that had no iodine from the beginning.

Lethal Power of Type I Pneumococcus.—Petrie and Morgan investigated the factors that influence the lethal power for mice of a virulent type I pneumococcus culture. They noted that the density and the virulence of the culture determine its lethal power. The controllable factors that influence the test animal were likewise examined. Stocks of mice from different sources appear to show some variation in susceptibility. There is no sex factor, nor does the weight factor influence the mortality, although it modifies the survival time. A small proportion of mice—from 5 to 10 per cent—possess an innate resistance to small doses of pneumococci. A characteristic curve relating dosage to percentage mortality among mice was obtained and furnished evidence that an average lethal dose of a culture can be calculated by the use of reasonable numbers of mice; this dose contains one diplococcus. The percentage mortality, the mean death time, and the distribution of the deaths in appropriate time intervals in a group of mice that receive a definite dose of a test culture are criteria by means of which the lethal power of any culture of type I pneumococcus may be specified.

Lines of Arrested Growth in Long Bones.—By roentgen examination, Harris has demonstrated that lines of arrested growth are of frequent occurrence in both animals and plants. In man, at the time of cessation of growth in the long bones, during the eighteenth to the twentieth years, such lines are normally laid down. In neonatal life, as a result of the catastrophic changes involved at birth, an arrest of growth concomitant with the loss of weight in the first week of life is of such frequency as to be almost a normal feature. During the whole period of growth any severe interference with metabolism, as a result of starvation, acute infection, or metabolic disease such as diabetes, induces premature senescence in growing tissues, and the fact is unfailingly registered in the structure of the bone by the production of a transverse line of arrested growth. The process of absolute cessation of growth in the long bones by cessation of proliferation in the cartilage columns, by calcification and ossification in which the transverse trabeculae are maximally developed, is a process common to the long bones of all mammals. Throughout the growth period this ultimate process of formation of a line of cessation of growth is kept in mind as it were; given any nociceptive stimulus, the process is initiated but pursued only to an extent dependent on the strength and duration of the stimulus. The process of arrest of growth in illness is a preliminary but incomplete exhibition of the ultimate cessation of growth which is the common fate of all growing animals. In certain cases the nociceptive stimulus is so severe that complete calcification and ossification of the growth cartilage occurs. This is seen in cases of children who, during the second decade, suffer severe infections in quick succession. Complete union of the epiphyses of the long bones in boys and girls of from 14 to 16 following severe exanthems has been reported frequently, and it is an index of the fact that the growth processes in the cartilage have been finally suppressed. Any hospital outpatient department will present cases of this type, many of them labeled "infantilism," whereas they are really examples of "premature senility" of the skeleton.

Skiodan. — Heathcote and Gardner report that skiodan, given intravenously in dogs up to 7 Gm. per kilogram of body weight, is nontoxic. The speed at which the injections are made does not seem to be important. The isolated heart and intestine of the rabbit are scarcely affected by solutions of skiodan of strengths comparable to those which might occur in man after administration of the normal dose. Skiodan, in doses up to 3.33 Gm. per kilogram, given intravenously, produces only minimal changes in the blood pressure. In larger doses, up to about 7 Gm. per kilogram, a fall of blood pressure is produced, which is less pronounced and less prolonged than that previously described with iopax. Up to 3.33 Gm. per kilogram, skiodan produces no appreciable effects on the respiration. With increasing dosage, however, there is a progressive slowing of the respiration. Death is caused at about 8 Gm. per kilogram from asphyxia. No pathologic changes were observed to occur in animals which had received large doses, 7 Gm. per kilogram, on one occasion, or which had been given 1.66 Gm. per kilogram daily for six days. Again, in the organs of animals previously rendered nephritic by uranium, there were found, following the administration of large amounts of skiodan, no changes other than those produced by the action of that metal. Skiodan is excreted by the kidneys of dogs rendered nephritic with uranium, although the rate of excretion is greatly reduced from the normal. As a result, the concentration in the urine may be less than that required to produce roentgen shadows. Skiodan is efficient in making the urine radiopaque and is a satisfactory medium for urography in dogs. It is superior to iopax in the speed with which it is excreted, in the dose necessary for the production of urograms and, in the dog at least, in their quality.

Yaws and Syphilis. — Hasselmann states that the fundamental biologic difference between the two spirochetes producing yaws and syphilis, respectively, rests on their different organotropism; i. e., their different behavior in the body tissue of the affected host. The two parasites are indistinguishable by morphologic staining and cultural methods so far. Spirochaeta pertenuis is ectodermotropic and not able to multiply and survive for any length of time in mesodermal layers. Spirochaeta pallida, on the other hand, invades all tissues, with preference to mesodermic tissues. This different organotropism explains the differences in the clinical course, pathology and immunologic phenomena of the two diseases. The terms primary, secondary and tertiary lesions, used in syphilis and indicating a certain sequence, should not be applied to yaws infection as they would be misleading. The successive stages of frambesial crops are most liable to overlap one another in such a way that the initial, primary lesion may persist throughout the stage of metastatic generalization and even change into a late, ulcerative form with no or only a modified metastatic crop of frambesids occurring. Immunity in both spirochetal diseases is that of antiaggressive immunity found in certain bacterial infections. It has a scale ranging from full susceptibility with unlimited propagation of spirochetes to low grade resistance with restriction of their multiplication and, finally, to full immunity in which the multiplication of the respective parasites is completely suppressed, and the spirochetes die out after their lifetime has elapsed. Heterologous immunity (cross-immunity) exists between yaws and syphilis, developing, however, much later than the homologous immunity. Coexistent infection with yaws and syphilis, as shown by clinical and experimental experience, is possibly due to the late onset of cross-immunity, thus explaining the presence of syphilitic lesions of the cardiovascular as well as of the central nervous system in patients showing at the same time frambesial efflorescences. There are no fundamental differences between the two spirochetal diseases in regard to serology and therapy, though in yaws infection arsphenamine is most efficacious with bismuth compounds far behind and mercury and potassium iodide of little or no value. Injection of killed spirochetal material produces the same serologic and immunologic phenomena as natural infection. Vaccine therapy, therefore, opens new lines for the preventive treatment of metasyphilis. On the basis of his observations the author concludes that, though belonging to the same group of spirochetosis, striking differences in the clinical course, the morphologic appearance and the histopathology of the lesions, general pathology and immunology —all of which are explained by the different tropism of the two respective parasites—prove along with epidemiologic reasons that framboesia tropica and syphilis are two distinct and separate disease entities.

A Common Physical Sign in Phthisis.—In 97 per cent of more than 500 cases of tuberculosis of the lungs and their hili Anderson heard a bruit over the subclavian triangles; in 3 per cent of the cases he heard a similar bruit over the first part of the subclavain arteries. The bruit resembled the one heard over the brachial artery as the pressure in the cuff is released during a blood pressure determination. It is unassociated with any cardiac bruit or with similar bruits which may be heard in any other of the branches of the aorta. Its intensity increases in expiration and is also increased by increased pressure of the stethoscope chest-piece. The intensity is also apt to vary somewhat from examination to examination. When present there have never been lacking other evidences of tuberculous infection of the lung apexes or their hili. In one third of the cases the bruit was bilateral; in rather more than one half it was found only on the left side, and in rather less than one sixth it was present only on the right side. In about one tenth of the cases in which it was unilateral it was present on the side opposite to that of the more severely affected lung. In cases in which this bruit was heard, hilar involvement could also be detected by percussion in more than half of the cases. Wasting or abnormally good development of the overlying muscles appeared to have no influence on the intensity of the bruit; indeed, its frequency in advanced cases of phthisis was only half that found in the whole series, and the frequency in ambulant cases twice that in hospital cases. The author designates this auscultatory sign of tuberculosis as the mediostino-arterial bruit.

*Erysipeloid: Transmission of Swine Erysipelas to Man. G. Belgodere. —p. 1241.

Erysipeloid.—Belgodere discusses the inadequacy of the term "erysipeloid," reviews the history of the disease, describes a personal case, and outlines the general characteristics and treatment of the disorder. Slight lesions allow the infecting bacillus to obtain a foothold and after an incubation period of one or two days erythema is the first symptom noted. This erythema occupies generally the dorsal aspect of the fingers or hand but may invade the palmar aspect and is of a deep wine color, nonelevated, clearly delimited and serpiginous, painless and more or less itchy. This period lasts about ten days. In serious cases infiltration may become more pronounced with consequent swelling of the parts; lymphangitis may appear with involvement of the corresponding lymph nodes, and even generalized infection may set in. Phalangeal arthritis is a frequent complication. Differential diagnosis is easily made from erysipelas, lymphangitis and erythema multiforme by observation of the peculiar characteristics of erysipeloid. The author fully describes the causative bacillus and states that this organism offers little resistance to heat, being killed in a few minutes at from 55 to 58 C., thrives in darkness, wet ground and water and is quickly destroyed by light and desiccation. Although the ordinary infections in man are usually of benign form, serious consequences and even death may follow contamination by cultures or by laboratory and vaccination accidents. Bacteriologic diagnosis attempted from a drop of blood taken from the border of the erysipeloid plaque usually results in failure; examination of the serous exudate from a blister or from lesions due to scratching is more likely to produce the desired result; histologic sections made from a piece of skin, especially if previously kept in a medium favorable to the reproduction of the bacillus, offer the best chances of success. The author discusses the prevalence of erysipeloid due to contact with marine fish and crustaceans, and mentions the finding of the bacillus in certain diseases of birds, poultry and sheep, and in river water, animal feces, decayed meat, dead mice, and so on. He states that it seems to be a well established fact that the bacillus of erysipeloid is only a common organism, prevalent everywhere and of unstable virulence. He outlines the study of immunity reactions made by several authors and finds proof of the production of exotoxins by the bacillus. Treatment of benign erysipeloid is limited to antiseptics, emollients or resolvents, especially sulphonated bitumen ointments; serious infections call for specific medication by serotherapy or vaccine therapy, which has been so successful in swine erysipelas. The author closes with the following adequate definition of the disease: Erysipeloid is a cutaneous disorder due to inoculation in the dorsal aspect of the hand of a special bacillus, called the bacillus of swine erysipelas because it is the pathogenic agent of this disease, but this bacillus is very prevalent and lives as a saprophyte on substances of animal origin and also on other animals whose contact may cause contamination.

*Measles and Tuberculin Cutireaction. P. Lereboullet and P. Baize. —p. 701.
Mechanism of Immunization by Calmette's Vaccine. B. Frias and E. J. Roldan.—p. 713.

Measles and Tuberculin Cutireaction.—Lereboullet and Baize assert that other allergic reactions besides the tuberculin cutireaction can be modified in the course of measles. During the exanthem in measles, changes have been noted in the Wassermann reaction, the Widal reaction and even simple intradermal reactions to foreign proteins. However, the Schick test is not modified. Measles is not the only infection capable of rendering negative a positive tuberculin cutireaction; others are influenza, whooping cough, typhoid, scarlet fever, german measles, chickenpox, diphtheria. Some of these are not accompanied by the slightest exanthem. Measles is the only disease that almost constantly suspends tuberculous allergy, whereas the other diseases, whooping cough, pneumonia, and typhoid show anergy only in exceptional cases (usually in the child); however, influenza, related clinically with measles, frequently modifies allergic states. The authors believe that the change from positive to negative of a cutireaction during measles is a proof of a temporary giving way of the allergic state and a local factor is responsible. This local factor is a catarrhal inflammation of the respiratory tract that causes engorgement and congestion of the corresponding lymph nodes, particularly the tracheobronchial ones. Under the influence of bacteria and their toxins, the old tuberculous foci are modified, the caseous tissue is softened, and the encystment becomes less marked; the bacilli multiply, mobilize, pass into the blood circulation and invade the body. The secondary infection thus acts mechanically by provoking the infection, the suppuration and the softening, of the bronchial lymph nodes. At the same time the phagocytic activity is decreased and the body resistance for the tuberculous infection becomes feeble. In summary, the positive tuberculin cutireaction disappears more completely and suddenly in measles than in any other disease, with the possible exception of influenza. The phenomena can only be the result of a truly specific disease and can be explained in the giving way of the protective immunity for tuberculosis.

New Contribution to Therapeutic Use of Bismuth Subnitrate and Kaolin. G. Hayem.—p. 1819.

Removal of Parathyroid Adenoma for Diffuse Lesions and Decalcification of Bones.—May and Lièvre review the history of a typical case in which surgical suppression of a parathyroid adenoma arrested immediately the decalcification processes and a considerable improvement was noted in the clinical, humoral and roentgen signs. The patient gave a history of an attack of renal colic four years before and presented osseous pains, extreme sensibility of the skeleton, spontaneous fractures, tumefactions, all leading to absolute immobilization and impotence, and intense bony decalcification demonstrated by roentgenography; the accessory symptoms were gastric crises, attacks of tachycardia and obstinate constipation; there was no hypercalcemia (the importance in diagnosis is loss of bone calcium and that is demonstrated in the calcium balance by loss of calcium in the urine and feces). Following the intervention there was a change in the calcium metabolism toward the normal and this was followed by skeletal recalcification with an improvement in the clinical manifestations. After the operation the patient had a grave attack of tetany with psychic disturbances. This was observed in many other patients. Partial parathyroidectomy does not prevent this condition. These accidents should disappear on treatment and do not materially affect the postoperative results.

Operative Technic in Amputation of Cancerous Rectum by Abdominoperineal Route and Lowering the Colon to the Perineum. R. Soupault and R. Leibovici.—p. 816.

Surgical Treatment in Angina Pectoris.—Leriche and Fontaine assert that surgical cure of angina pectoris is possible. Three interventions have been reported: namely, the removal of all the cervical sympathetic chain with the stellate ganglion, the removal of the cervical chain to the level of the stellate ganglion, cutting the supero-external branches, and the removal of the stellate ganglion itself. The authors believe the question of the choice of an operation depends on the conservation or the suppression of the stellate ganglion, the center of the reflexes causing the crisis in angina pectoris. The results previously reported and the results (seventy-eight observations) of the present study led the authors to conclude that the extirpation of the stellate ganglion, whenever indicated, is not more dangerous than extraganglionic interventions. This intervention has succeeded when others have failed. One stellate ganglion should first be removed and, when this seems insufficient, the other ganglion should be removed. Success depends on the choice of the proper indications.

Journal de Médecine de Lyon

12: *733-766 (Dec. 20) 1931*

Anatomic Study of Malignant Pleuropulmonary Granulomatosis. M. Favre, P. Croizat and A. Guichard.—p. 733.
*Histopathology of Gastric Ulcer: Fifty-Two Gastrectomies. J. F. Martin and F. Rouquet.—p. 747.
*Nervous Forms of Malignant Granulomatosis. M. Favre, J. Dechaume and P. Croizat.—p. 757.

Histopathology of Gastric Ulcer.—Martin and Rouquet made microscopic examinations of fifty-two gastrectomy specimens. They assert that a histologic study in gastric ulcer should include material not only from the ulcerous lesions and the immediately adjacent parts, but also the gastric wall at some distance from the lesions. Their observations prove that all the tissue layers of the gastric mucosa are affected by the ulcerous condition and undergo two types of modification if the lesion has reached a sufficiently chronic state. 1. There is a process of destruction in the mucosa, primarily on the surface but with infiltration accompanied by acute, subacute or chronic types of inflammatory reactions, responsible for secondary degenerative lesions of the epithelial cells, muscular fibers, connective tissue and nervous tissue. 2. There is a process of reparation and neoformation in the entire gastric wall; in the mucosa it is supplemented by erosive lesions due to periulcerous gastritis with atrophies and cicatricial or hyperplastic type of glandular repair (diffuse glandular hyperplasia, marginal pseudo-adenomas and microcysts.) The hyperplasias of the muscularis mucosae and the muscle coat are diffuse or localized and can lead to the formation of true myomas; the hyperplasia of the serosa is of a periulcerous lipoma origin: the myomatous thickening of the vascular walls and the neuromas are the expression of the same type of hyperplasia. The provocative cause of the gastric ulcer is connected with an inflammatory process which is sufficiently slow, destructive and regenerating at the same time and often forms the tumor type: this takes the aspect of marginal adenomas, soft myomas, lipomas and neuromas but not true benign tumors of the mucosa, muscle, adipose tissue or nerves: the single inflammation is the cause of these pseudotumoral hyperplasias. The authors in their study of the stomach state that the general rules of Favre and Dechaume apply: that, in an organ with chronic inflammation, the glandular elements that remain become organized, and together with the processes of degeneration there are parallel processes of neoformation and reconstruction; inflammatory epithelial neoformations resemble adenomas morphologically but nevertheless are not benign tumors. Nonepithelial tissues under the influence of chronic inflammation can also undergo hyperplasia and take on pseudotumoral aspects.

Nervous Forms of Malignant Granulomatosis.—Favre and his co-workers assert that anatomopathologic studies prove that most frequently the nervous manifestations of malignant granulomatosis in the region of the neural axis are nonspecific lesions of the neighboring structures. The granuloma penetrates into the bony canal or develops in situ at the expense of the bone or of epidural connective tissues. The granuloma cannot penetrate the dura mater, which acts as a strong barrier against granulomatous infiltration. The neural axis presents therefore only nonspecific lesions of a toxic or mechanical character due to compression by the contiguous granulomatous neoformation. In exceptional cases (one personal observation in 1913), the granuloma invades the neural axis, which then presents specific lesions. The leptomeninges undergo granulomatous change. The cells of the granuloma infiltrate the connective tissue sheaths and finally penetrate the nerve tissue itself. Invasion can take place at a distance from the cortex by vascular metastasis. This specific involvement of the neural axis raises the question of the behavior of the oligodendroglia in this condition. There is no histopathologic proof of a primary nervous form of granulomatosis. The clinical study reveals the protean character of the nervous manifestations whose anatomopathologic substratum is so variable. The cerebral manifestations consist of localizing neurologic signs or signs of intracranial hypertension associated or unassociated with osseous lesions. The spinal cord manifestations resemble those of compression, simulating Pott's disease, spinal neoplasm, and primary meningoradicular lesions. Aside from the characteristic roentgen picture of the spinal lesions there is not any specific criterion. A combination of the anatomic and clinical observations are against the theory of the existence of a primary nervous form of malignant granulomatosis. Infiltration of the nervous parenchyma, when it exists, is always secondary to another focus of granulomatosis. Roentgen therapy, although not curative, is effective for retarding the evolution of the nervous accidents that occur in the course of malignant granulomatosis.

*Loewenstein's Blood Culture Method in Diagnosis of Tuberculous Bacillemia. I. Nanu, D. Jonnesco and C. Stefanesco.—p. 1805.
Blocked Hypertension. A. Dumas.—p. 1807.
Skin Disturbances in Venous Diseases: Varicose Ulcer. G. Delater.—p. 1808.

Loewenstein's Method in Diagnosis of Tuberculous Bacillemia.—Nanu and his co-workers assert that Loewenstein's blood culture method for the tubercle bacillus may be added to and in some instances replace the usual methods of direct examination or the inoculation into guinea-pigs. Loewenstein's medium contains monopotassium phosphate, sodium citrate, magnesium sulphate, aspargin, glycerin, starch, yolk of egg, congo red or malachite green. From 10 to 30 cc. of blood is collected in 10 per cent solution of sodium citrate, centrifugated and decanted, and 10 cc. of a 5 per cent solution of acetic acid is added. This is allowed to stand five minutes, is centrifugated and decanted again; the clot is washed in distilled water until the hemoglobin is removed, is inoculated into three or four tubes, and is placed in a thermostat. The cultures become visible in two weeks and the growth is abundant in one month. There should also be a control by direct examination and inoculation into guinea-pigs. Loewenstein reported encouraging results in the cultures from pulmonary, cutaneous, renal, articular and ocular tuberculosis and acute rheumatism (the latter, twenty-one cases, all positive). The authors in this report assert that blood cultures, in twenty-one cases of suspected tuberculosis or rheumatism, proved positive in one case of tuberculous pleuroperitonitis and one case of acute polyarticular rheumatism with endocarditis and pericarditis. This method may also be used for examination of pathologic material, negative on direct examination. In that case it is advisable to wash the substance several times in 15 per cent sulphuric acid to eliminate associated micro-organisms. The authors obtained positive results within nine days from cultures of purulent pleural fluid, within ten days from purulent arthritis of the wrist, and within nine days from serohemorrhagic pericarditis. A blood culture in a case of inguinal adenopathy resembling tuberculosis was negative, however. The authors believe that culture for tubercle bacilli may be advisable when direct examination is negative.

Consideration of Various Mineral Waters Used in Treatment of Rheumatism. Mathieu-Pierre Weil.—p. 1853.
Postrachianesthetic Paralysis of Craniospinal Motor Nerves. C. Angelesco and S. Tzovaru.—p. 1855.

Effect of Temperature Changes on Phenomena of Clinical and Experimental Sensitization.—Pasteur Vallery-Radot and his co-workers assert that their observations (forty-five patients) substantiate their belief that temperature influences crises in asthma of the adult. In order to be effective, this temperature must attain a "threshold" value rarely lower than 38.5 C. (101.3 F.). Hypothermia or hyperthermia can prevent anaphylactic shock but the eventuality is not distinctly a matter of cause and effect. The authors conclude that in man hyperthermia prevents the clinical manifestations from being produced in certain conditions of hypersensitivity; in the animal these thermic modifications inhibit the manifestations of anaphylactic shock. In man, hyperthermia has no action on anaphylactic antibodies and hence there is no desensitization; the same is true in the animal. In the hypothermic or hyperthermic animal a second injection usually succeeds in desensitizing. Pyretotherapy can be used in human anaphylaxis, not to remove the state of hypersensitivity, since the antibodies are responsible for that, but to make the conditions suitable for desensitization. Certain anaphylactic syndromes can be treated by an association of hyperthermia and desensitization.

Ketogenic Diet in Epilepsy.—Pagniez and Plichet assert that this diet should be adhered to as strictly as a regimen in diabetes. It consists in the suppression of carbohydrates, the replacement of the carbohydrates by fats and fatty substances, and the reduction of nitrogenous substances (meat). Before this diet is begun the patient is put on a reduced water diet for forty-eight hours. The second day, if the hunger is unbearable, the patient is given for his noon and evening meal a salad with plenty of olive oil. If the patient should get thin, the diet should nevertheless be continued. Constipation should be combated by magnesia, liquid petrolatum or castor oil. This regimen should be continued until there has been improvement or sedation. An exact record of the number of attacks should be kept. Acidosis, which is the result of this diet, is not the important factor. Recent workers believe that the action is due to a modification in the water metabolism. Whatever the exact interpretation may be, the authors recommend this regimen in view of the favorable results they have obtained.

*Hyaline Degeneration of Spleen Associated with Chronic Lead Poisoning. A. Fontana.—p. 813.
Chloridemia in Patients with Benign and Malignant Tumors. M. Mairano and S. Teneff.—p. 820.
Subacute Leukemia: Cases. L. Ferrannini.—p. 824.

Hyaline Degeneration of Spleen in Chronic Lead Poisoning.—Fontana states that he never saw such marked hyaline degeneration of the spleen as he saw in a patient aged 53 who died as a result of a grave attack of uremia. The clinical diagnosis was chronic lead poisoning, hypertension due to malignant nephrosclerosis, cardiac hypertrophy, visceral stasis and left hydrothorax. He calls attention to this special condition associated with chronic lead poisoning because such a diffuse and grave hyalinosis should not be confused with ordinary arteriosclerosis of the vessels of the spleen; also owing to the complete absence of vascular calcification and the slight positive reaction obtained for the fats with the sudan dye and osmic acid. Something had certainly intervened (lead) that had caused a fibrous vascularitis, an endarteritis obliterans, a hyalinization prevailingly arteriocapillary in which, according to the conception of Pende, the syndrome, owing to the constitutional abiotrophic character of one or more organs, was developed, and was speeded up by the chronic intoxication.

*Modifications of Acid-Base Equilibrium of Cerebrospinal Fluid in Some Pathologic Conditions. C. Manzini and P. Caramazza.—p. 1.
*Clinical and Anatomopathologic Contribution to Study of Extramedullary Tumors. F. Sabatucci.—p. 13.
*Malignant Lymphogranuloma. G. Jona and G. Dalla Torre.—p. 25.

Modifications of Acid-Base Equilibrium of Cerebrospinal Fluid.—In a study of the acid-base equilibrium of human cerebrospinal fluid, Manzini and Caramazza found a hydrogen ion concentration varying between p_H 7.41 and p_H 7.46 and an alkali reserve of from 43 to 50 volumes of carbon dioxide per cent. They think that the slight degree of alkalinity of normal cerebrospinal fluid compensates, through its relative autonomy and lack of corpuscles, for its lower content of bicarbonate. This possibly explains why it possesses a lower regulatory power than the blood serum although its p_H is practically equal to that of the blood. It is consequently necessary to estimate not only the hydrogen ion concentration but also the alkali reserve in studies of the acid-base equilibrium of cerebrospinal fluid. Variations from normal are found especially in inflammatory conditions of the meninges and depend on the gravity and form of the disease. In acute meningitis there is a true acidosis and in the tuberculous form one finds an uncompensated acidosis. Hydrogen ion concentration is lowered but seldom in the final stages of the disease. In meningism and serous meningitis the acid-base equilibrium remains unaltered; also in syphilitic conditions of the cerebrospinal axis if there are no concomitant meningeal lesions, in cerebral tumors and in hydrocephalus. In neoplasm of the hypophysis with syndrome of diabetes insipidus and in true uremia a well defined true acidosis is encountered. In the uremia of eclampsia there is no modification.

Extramedullary Tumors.—From the clinical and anatomopathologic point of view Sabatucci discusses a case of intradural extramedullary tumor that gave rise to peculiar manifestations: (1) protracted course of the disease over many years with but few clinical symptoms in the presence of a malignant tumor; (2) peculiar aggravation of the symptoms after an injection of iodized poppy-seed oil 40 per cent, which introduces a reasonable contraindication for cases in which opportunity for a surgical intervention exists; (3) favorable results of roentgen therapy when surgery was necessarily partial, and (4) anatomic rarity of the tumor, which was a fibroblastic sarcoma of angiomatous type.

Malignant Lymphogranuloma.—Jona and Dalla Torre state that malignant granuloma is an entity clearly defined by its clinical symptoms and histologic characteristics and that, although in many cases it cannot be diagnosed by direct observations, pathognomonic proof of its presence consists in the finding of Sternberg's tissue with its typical polynucleated cells. Malignant lymphogranuloma does not belong to the hyperplasias or to the neoplasias but is essentially an inflammatory process. This is evidenced by its clinical appearance with febrile periods and intermittent enlargement of the spleen and liver; its histologic changes which testify to its inflammatory type; the inflammatory character of the splenic tumor which is always present even when not of actual granulomatous nature. Malignant granuloma is a specific granulomatous process without any relation to tuberculosis: this is proved by uncomplicated cases, which evolve from beginning to end with their proper characteristics distinct from those occurring in tuberculosis; cases in which histologic and biologic examinations exclude tuberculosis and in which there is complete absence of any reaction to tuberculin. Frequent association with tuberculosis explains the contradictory reports on histology of and experimentation on granuloma. From the clinical point of view, classification of malignant granuloma is founded on its topographic distribution: peripheral form including cervical and cervico-axillary-inguinal, mediastinal form including splenomesenteric and gastro-intestinal, and cutaneous form. From the point of view of its effects it should be divided into a mechanical form with disturbances occasioned by its different sizes and a toxic form with special repercussive effect on the circulatory system and production of fatal anemia. The course of malignant lymphogranuloma may be acute, subacute or chronic with remissions, and leads to death in from one to five years. Its etiology is still obscure and its therapy unsuccessful.

Prognosis of Chronic Pulmonary Tuberculosis. J. J. Bosco.—p. 4.
*Surgical Treatment of Pott's Disease by Costal Implant. A. Gutierrez and B. Labandibar.—p. 14.
Work of Cured Tuberculous Patients. L. Bard.—p. 27.

Surgical Treatment of Pott's Disease by Costal Implant.—Gutierrez and Labandibar recommend the use of a costal implant because it is available to the surgeon in a preliminary operation without moving the patient or leaving its preparation to an assistant, it offers the anatomic requirements of a good implant and represents adaptable material on account of its flexibility. Both steps of the operation can be done under local anesthesia. In the first step the skin and subcutaneous cellular tissues are infiltrated with a 0.5 per cent solution of procaine hydrochloride, the muscles with a 0.25 per cent solution and the intercostal nerve at the posterior end of the incision with a 0.5 per cent solution. The technic calls for an incision parallel to the rib and in the form of a supine C which allows of ample exposure of the desired rib segment and of eversion of the skin flap. The incision should be 4 cm. longer than the implant, which should be cut anteriorly to the costal angle of the seventh, eighth or ninth ribs and should not include any part of the cartilaginous portion. Two incisions of the periosteum are made, one on the upper and one on the lower border of the rib so as to conserve the anterior part of the periosteum. In dissecting the implant, one should take care not to injure the parietal pleura. In the second step, anesthesia is obtained as in the first with a 0.5 per cent solution of procaine hydrochloride for the superficial tissues and a 0.25 per cent solution for the muscles. A curvilinear incision takes the flap away from the median line and avoids superimposition of the cutaneous with the deeper incision. The flap dissected and everted is isolated from the field of operation with gauze, the spinal processes are exposed, and the supraspinous and interspinous ligaments are sectioned in the median line. The spinal processes, two above and two below the lesion, are split vertically to the vicinity of the neural arch and fractured on one side, the angularity of the fracture is corrected by transverse pressure exerted on both sides, and the implant is inserted. Two distal sutures of heavy catgut through the supraspinous ligaments and the muscles serve to retain the implant, then a central suture followed by the remaining ones complete fixation. Patients are put on a hard bed for thirty or forty days before being allowed to walk. Plaster-of-paris, celluloid or ordinary reenforced corsets are used for from four to six months. Results have been uniformly satisfactory in the eleven patients treated by the authors, who advise against this operation in patients presenting tuberculous abscesses or fistulas, advanced visceral lesions of tuberculous nature or cachexia.

Laryngeal Cancer and Its Treatment. J. C. Gros.—p. 897.
Impressions of a Scholar: Part III. R. Machin.—p. 910

New Procedure in Hysteropexy.—According to Clark, this new procedure is to be used only after the menopause. He uses the median incision below the umbilicus, splits the uterus anteroposteriorly down to the supracervical segment, and paints the mucosa with tincture of iodine. If the uterus happens to be congested, an assistant compresses the uterine arteries. Deep dissection of the mucosa follows, with resection at the lower limit of the incision and cauterization of the cervical canal. Three sutures of number 3 chromic catgut embracing the denuded uterine cavity close each half of the uterus; one suture is used circularly under the serosa to close the upper part of the cervical canal. An incision is made through each rectus abdominis muscle, the corresponding half of the uterus is pulled through, and the two halves are sutured together in the median line. Simple drainage with gauze is advisable.

Painful Nodular Growths of Ear.—Fernández and Monserrat report a case of painful nodular growths in the ear of an adult. They regard the condition as an entity readily differentiated from epithelioma, cysts, gouty tophus, lupus erythematosus, several types of verrucae, keratosis senilis and the darwinian tubercle. The authors review the physiologic, topographic and histologic description of normal and pathologic glomi given by Masson in *Lyon Chirurgical* **21**:257 (June) 1924 (abstracted in The Journal, Aug. 23, 1924, p. 648). Humoral proliferated glomi developed into small hard tumors, which were designated by Masson as angioneuromyomas. They may develop, in either an isolated or a multiple form, in any of the tactile dermal areas, although the greater frequency of their development as well as the larger number of nodules in an area is in relation to the greater or lesser tactile function of the organ. The causation is unknown, although in some cases trauma has been considered as the etiologic factor. The diagnosis is made by the clinical and histologic characteristics. The most important clinical symptom is a radiating and severe pain in the nodules. A profuse bleeding is provoked when the nodule is detached from its seat. The histologic examination of the tumor proves that it is formed by nervous, muscular and epithelioid cells around a vessel which acts as the center for the development of the tumor. The authors believe that the name of either glomic tumors or Masson's angioneuromyoma is more proper to designate the condition than the several names of "painful nodules of the ear," "chondrodermatitis nodularis chronica helicis," "chronic development of nodules in the ear," or "pathologic growths in the cartilage of the pinna," which heretofore have been given to the condition.

Influence of Potassium on Pruritus.—Sauer points out that although the sodium and calcium ions have been thoroughly investigated, little is as yet known about the therapeutic and physiologic action of the potassium ion. How he came to study the therapeutic action of the potassium ion he illustrates in the clinical history of a woman who had severe pruritus and occasionally urticaria. Influence of warmth made the pruritus more intense and for this reason the patient suffered most severely at night. This factor was considered indicative of a hypersensitivity of the sympathetic nervous system and the itching was designated as "sympathetic pruritus." Since various therapeutic measures, such as diets free from sodium chloride and deficient in protein, or acid or alkaline diets, or the application of epinephrine or calcium chloride urea were ineffective, sodium bicarbonate was tried, but this likewise was ineffective. However, when potassium bicarbonate was given, a considerable improvement was noted. In order to determine whether the efficacy was due to the potassium ion, potassium acetate was administered, and on the following day the pruritus had almost completely disappeared. Because of this favorable result the author employed the potassium therapy also in other cases of sympathetic pruritus. Patients with chronic lichen urticatus, in whom ointments and irradiations had proved ineffective, were given three times daily a tablespoonful of liquor potassii acetici, 30 cc., and aqua destillata, sufficient to make 200 cc. After two days the pruritus had disappeared but the skin eruption was not changed, but after eight days a gradual improvement became noticeable; yet after two weeks it appeared as if there was no further progress in the curative process and the pruritus recurred temporarily. In order to reactivate the potassium action, calcium lactate was given for one day and as a result of this the pruritus and eczema showed an exacerbation, but when potassium acetate was given once more the healing progressed further. Of nine patients with lichen urticatus, only two were refractory to the potassium therapy and both of them were men. In women the treatment was much more effective. Several cases of chronic eczema of the hands likewise yielded to potassium therapy.

Investigations on Mode of Action of Potassium.—In this paper Sauer reports his studies on the mode of action of potassium. His conclusions are as follows: 1. Oral administration of large doses of potassium acetate effects an increase in the potassium content of the serum and of the cerebrospinal fluid. 2. The calcium values in the serum soon follow this increase, for the ratio of calcium to potassium remains unchanged. 3. There is a displacement of the sodium from the serum. 4. The disappearance of the sympathetic pruritus following potassium therapy is not dependent on an increased potassium content of the serum.

Gelatin Tolerance as Functional Test of Liver.—Mancke and Rohr describe a tolerance test with gelatin and water which is suitable for clinical purposes. The alimentary hyperamino-aciduria indicates the severity of the disorder. By means of this test, disturbances in the intermediate protein metabolism can be determined. In order to differentiate the alimentary hyperamino-aciduria from that form caused by increased diuresis, a water tolerance test is made. The authors report about eighty-seven gelatin-water tolerance tests and about fifteen water tolerance tests on healthy persons and on those with disorders of the liver. The observations are compared with the results of the insulin-dextrose-water tests and of the galactose test. In normal persons the elimination of the amino nitrogen goes parallel with the quantity of urine. The concentration of the urine remains constant within comparatively narrow limits. Following a gelatin-water tolerance test there is a slight increase in the concentration, as an expression of the low alimentary hyperamino-aciduria of the normal person, but during the corresponding water tolerance test the concentration of the urine remains practically constant. The average concentration of the amino nitrogen in the urine of the normal person is, when determined according to Folin's method, about 25 mg. per hundred cubic centimeters, and after the gelatin-water tolerance test, it increases to 28 mg. In icterus catarrhalis gravis there is often a spontaneous hyperamino-aciduria, and besides this a marked alimentary hyperamino-aciduria can be produced by the gelatin-water tolerance test. In cases of minor severity, without an increase in the amino nitrogen of the urine, there develops, following the tolerance test, likewise a marked hyperamino-aciduria. Gradual differences can be demonstrated between these cases of icterus and acute atrophy of the liver. In the various forms of cirrhosis of the liver, without manifest stasis of the portal vein, there exists alimentary hyperamino-aciduria, which, corresponding to the developmental stage of cirrhosis, varies in severity. The authors show that an early diagnosis of cirrhosis of the liver is possible by a comparison of the results of the insulin-dextrose-water test with those of the gelatin-water test.

Bactericidal Power of Blood During Tonsillitis.—Vogel found that the bactericidal index of the blood is reduced in the course of every acute tonsillitis. It increases again, not synchronously with the improvement of the clinical manifestations, but only some time thereafter. This reduction of the bactericidal power of the blood is of no significance for the etiology of sequelae, for all, except one, of the cases on which the author made his observations ran their course without complications.

Irradiation in Cancers of Female Genitalia.—In a tabular report, Weibel shows the frequency with which he employed either surgical and ray therapy combined or irradiation alone, in 350 cases of genital cancers during 1929 and 1930 and in 127 cases during 1931. In both periods nearly all the women with genital cancers were subjected to irradiation, but in 1931 the percentage that was given only ray treatment was larger than in the preceding period. When surgery was not resorted to, irradiation was always given as a combination of roentgen and radium treatment. In the first two years, roentgen therapy was the only form of irradiation used for postoperative treatment as well as for inoperable cases, because the available quantity of radon was limited. However, during 1931 radium was more extensively used. Preoperative irradiation with either roentgen rays or radium was never employed by the author, but he does not advise against it and thinks that in certain cases it could be tried. The postoperative roentgen irradiation he considers advisable for all cases. Combined radium and roentgen therapy is especially indicated for carcinoma of the cervix, whereas cancers of the corpus uteri are usually removed by surgical intervention. Vaginal carcinomas are frequently refractory to surgical treatment as well as to irradiation, but the author's own observations as well as those of others indicate that they yield best to radium irradiation. In carcinomas of the vulva, which likewise are difficult to influence, he employed surgery and postoperative irradiation. The ovarian carcinomas present a difficult problem, because they frequently are already inoperable when treatment is begun. In the majority of those which came under the author's observation, surgery and postoperative roentgen irradiation were resorted to. In regard to the technic of postoperative roentgen treatment, it is stated that the formerly customary treatment with large doses has been abandoned in favor of a prolonged treatment with smaller doses. The latter technic has also been adopted for inoperable cases.

Irradiation of Carcinoma of Skin and Lips.—Comparison of the results of a combination surgical and radium therapy with the results of exclusive radium treatment convinced Arzt and Fuhs that in carcinoma of the skin and of the lips these two methods are of about equal value. In consideration of this, it appears advisable to employ radium therapy exclusively, but the authors nevertheless employed in the majority of cases the combination of surgery and radium. The main reason for this procedure was the fact that exclusive radium treatment not only requires much more time but also necessitates the use of greater doses of rays, the latter being an important factor when the quantity of radium is limited. As to whether the surgical removal should be done with the knife or with the diathermic loop, the authors favor the latter. In analyzing their material according to the location of the carcinomas, they found that in carcinoma of the ear exclusive radium treatment fails, and consequently they consider the combined surgical and radium treatment absolutely necessary in such cases. In most other localizations the combination therapy gives about the same results as radium treatment alone. Only in carcinoma of the lip did the authors generally find exclusive radium treatment to be the method of choice.

Studies on Person with Giant Growth Following Arrest of Growth.—Mandl and Windholz report the case of a man with acromegalic giant growth, which set in after a marked inhibition of growth. The anamnesis revealed that at the age of 18 the patient's height was only 138 cm. (4 feet 6½ inches). The pathologically increased growth set in at the age of 21. At present, at the age of 31, the patient is 216 cm. (over 7 feet) tall. The present status is characterized by an enormous endosellar tumor, also by acromegaly and by hypogenitalism. As symptoms that differ from those mentioned in other reports the authors mention galactorrhea, the presence of female sex hormone in the urine and an abnormally small heart, with hypotony of the vascular system, while otherwise splanchnomegaly prevailed. Roentgenoscopy revealed a diffuse osteoporosis and a marked increase in the size of the skeleton. Many of the epiphyseal synarthroses were open. The sella turcica was enormously enlarged. The sternal termination of the right clavicle showed an extensive defect. The pneumatization of the temporal bone and the development of the frontal sinuses were inhibited. Anthropometric measurements revealed an abnormal shortness of the trunk and asymmetry between right and left. The enlargement was especially marked on the upper arms, thighs, hands, feet and face. The authors also discuss the causes of the developmental inhibition in the early life of the patient, and cite factors that speak against a pituitary origin. They finally assume a causal relation to cretinism. The patient underwent an operation for removal of a hypophyseal tumor, and the microscopic examination of the surgical specimen revealed an immature adenoma. The authors express the opinion that in the reported case there existed no primary growth tendency but that the giant growth was due to an increased reactiveness of the organs sensibilized by growth inhibition for the pathologic growth stimulation exerted by the hypophyseal tumor.

Spino-Umbilical Reflex in Chronic Appendicitis. I. Stoia and M. Stanescu.—p. 506.
Intravenous Pyelography with Methiodal. S. Gavrilescu.—p. 508.

Transscapular Extrapleural Thoracoplasty.—Teodorescu asserts that extrapleural thoracoplasty as a surgical measure in the treatment of pulmonary tuberculosis merits the attention of clinicians and surgeons. The author uses the method of Sauerbruch, which he believes has advantages over other methods. The intervention is performed in the interscapulovertebral region with an incision preferably in the median line. The scapulovertebral muscles are cut parallel to the vertebral column, beginning at the lumbodorsal muscles. The costal transscapular approach makes the intervention more convenient so far as inundation, clearness and working space are concerned; and bleeding and pain are minimal. The author uses as local (regional) anesthesia a 1.5 per cent solution of procaine hydrochloride.

Experimental Study of Case of Herpes Recurrens.—Klodnitskiy and Danilova discuss the literature on the subject of viruses and their place in microbic dissociation. The material for their experimental study was obtained from one of the authors who in 1924 became infected through contact with two patients with epidemic encephalitis. The disease took an abdominal course and did not demonstrate herpetic symptoms until 1926. At first the vesicles appeared twice a year and later four times a year. Nicolle in Paris (1928) studied the virus and came to the conclusion that the strain was related to the rabies virus, but this was not conclusive. The authors used rabbits, guinea-pigs, mice and marmots for experimental animals. Injections from the herpetic vesicles were made subdurally, into the cornea, into the parathyroids, intraperitoneally, intramuscularly, and into the ear, trachea, brain, and salivary glands. Material for inoculation consisted of the pustular material itself and its cultures in broth. The authors believe that no matter in what part of the body the virus may be it affects the skin and may be found in the peripheral blood. Inoculation of the cornea with herpetic peripheral blood leads to 16 per cent loss of weight, and inoculation subdurally leads to 20 per cent loss in weight. Virus material injected into the cornea or the brain of rabbits caused encephalitis and death. The brain of the infected animal inoculated into another animal again caused encephalitis. The authors conclude that their strain of herpes virus had a strong neurotropic power. Infection through the cornea in guinea-pigs was characterized by encephalitis, loss of weight and abdominal symptoms. The cutaneous manifestation of herpes is a tendency toward attenuation and may be used for experimentation and therapy. After cutivaccination, the virus is present in the peripheral blood. Corneal or subdural inoculation causes loss of weight and lethal encephalitis that can be transmitted from animal to animal.

Associated Factors in Tabetic Osteo-Arthropathy.—Toporkov asserts that arthropathy in tabes is not frequent but is very serious. There is no conclusive therapy. The pathogenesis may be attributed to a dystrophic tendency and syphilis of the joints. Among the associated factors, the author stresses trauma, especially in tabes. In this relation, disturbance of the osteo-articular process leads eventually to complete invalidism. Most workers recommend antisyphilitic therapy aimed at the active syphilitic process, which tends toward trophic disturbance of tissue. Early roentgen diagnosis of silent arthropathic processes in tabes and energetic antisyphilitic therapy together with ordinary preventive measures are important in treatment and prophylaxis. That trauma is an important factor is proved by the fact that persons doing physical labor most frequently develop arthropathies. The author recommends examination of those syphilitic persons who are engaged in work that may lead to trauma of the joints. In a review of the literature he mentions four workers who observed 1,149 instances of arthropathy and found 39.9 per cent in the knee joints, 20.2 per cent in the pelvis, 12.0 per cent in the shoulders and 5.7 per cent in the feet. Most of the complications are in the lower extremities and are most frequently the result of trauma. The author discusses the case history of a patient with arthropathy of the spine due to a combination of tabes and compression of the spine.

Experiences in Myelography. E. Ruin.—p. 875.
*Glaucomatous Hemorrhagic Iritis with Thrombopenic Purpura: Case. S. Werner and E. Adlercreutz.—p. 883.

Rheumatic Iritis and Weather.—Enroth thinks that there may be a certain relation between the onset of rheumatic iritis and the weather, especially that changes in the weather are of significance, because of unknown factors, as possibly disturbances in the heat regulation of the body or its electrical condition.

Sensibility of Cornea in Trachoma.—Of the seventy-three eyes examined, in cases with trachomatous pannus of from two weeks' to forty years' duration, the sensibility of the cornea was slightly decreased in eleven, moderately in thirty-five, greatly in twenty-two, and extremely in three; two were normal or nearly so. Zitting concludes that trachomatous processes reduce the sensibility of the entire cornea, particularly in the field of the pannus formation. The closer the pannus, the greater its extent, and the older the trachoma, the more marked is the reduction. Disturbances in sensibility are demonstrable after healing of the trachoma. The cases are tabulated.

Roentgen Irradiation and Ability of Tumors to Store Iodine.—Jansson's experiments, mainly on Jensen's rat sarcoma, show that more intensive irradiation, whether with a strong or a weak filter, decreases the ability of the tumor to store iodine, while its ability to store bismuth is increased by irradiation.

Glaucomatous Hemorrhagic Iritis with Thrombopenic Purpura.—The sudden hemorrhagic iritis with increased pressure in the case reported by Werner and Adlercreutz was resistant to energetic treatment continued for two months. At the end of that time a pronounced hemorrhagic diathesis with thrombopenia set in. Death occurred after two weeks. There was no hemorrhage from the mucous membrane of the mouth, and the thrombocyte count was 87,000. Acute leukemia, hemorrhagic aleukia and aplastic anemia were excluded. The relation between the hemorrhagic glaucomatous iritis and the thrombopenic purpura is not clear.

THE POSTGRADUATE AND GRADUATE TEACHING OF RADIOLOGY *

ARTHUR U. DESJARDINS, M.D.
ROCHESTER, MINN.

Radiology is still a comparatively new branch of medicine, but its rapid development during the last thirty-five years, and especially during the last ten years, is deservedly attracting widespread attention. Moreover, its relations to many other phases of medicine are increasing day by day. In several phases of medical practice, in fact, radiology has already become an indispensable factor. Such evolution has been so rapid that, although many of the better medical schools provide more or less substantial instruction for undergraduates, little effort has yet been made to organize and provide thorough postgraduate or graduate courses. In this respect America has allowed itself to fall behind several European countries. In England, France and Sweden, for instance, the teaching of radiology is well organized and has been placed on a higher plane than in any school in this country. This deficiency is now crying for correction.

Any consideration of postgraduate and graduate instruction in medical radiology must take into account a number of factors: the present status of the subject as it affects, and is affected by, other phases of medical practice; the existing plane of undergraduate teaching of radiology; the number of qualified teachers available, and the objects which an ideal system of instruction should seek to attain. It must be obvious that, without an ideal to strive for or a definite objective to attain, it would be difficult or impossible to construct a plan that could be expected to yield the desired result. In other words, the first essential is to know what is the desired result and to keep it clearly in mind. The main object of postgraduate instruction in radiology, it seems to me, should be to develop full-fledged specialists in this branch of medicine, masters of the subject, thoroughly equipped to practice the specialty, and worthy of public confidence. This, then, should be the ideal toward which we should strive. But before constructing a plan to achieve this result, it is important to inquire into the present status of radiologic practice. In a recent analysis I [1] have attempted to point out some of the undesirable conditions that characterize such practice at the present time, such as the comparatively low standards that countenance the reference of patients by their attending physicians to so-called laboratories operated on a commercial basis by unqualified laymen, the dependence of many physicians on interpretations of roentgenologic data by nonmedical technicians, the treatment of patients by technicians without supervision by medically trained therapeutic radiologists, and the dearth of teachers of academic caliber. These different factors are so closely interrelated that to analyze and set forth precisely the influence of each factor is not a simple task. Nor is such exact distinction necessary. It is quite enough to know that these factors collectively constitute a sort of vicious circle. The one point at which this circle can be most effectively broken is that which relates to postgraduate instruction, because the present lack of such instruction furnishes the best opportunity for constructive action. It is true that the break is rendered difficult by the relative paucity of teachers, but the number of teachers can be increased only by such a break.

Besides developing full-fledged specialists, however, the scheme of instruction should also include short courses in the different phases of diagnostic and therapeutic radiology. This would satisfy a widespread demand, would spread the knowledge of advanced methods, and would tend to raise the general level of radiologic practice.

A well considered scheme of instruction, therefore, should provide:

1. Short, strictly postgraduate, courses in different phases of diagnostic and therapeutic radiology for graduate physicians who may merely wish to keep informed on the value of various new methods or to prepare themselves to utilize one or another phase of radiology, and also for radiologists who may want to keep abreast of the newer technical developments and methods.
2. A comprehensive, graduate course of systematic and thorough instruction in every phase of radiology for physicians who desire to qualify as specialists.

The short courses should be open to any graduate physician, regardless of the character of his practice. This suggestion will no doubt be objected to by some, who may feel that to allow any physician to take such courses must result in encouraging physicians in general to conduct roentgenologic procedures or radiotherapy for themselves and in restricting the field of the radiologic specialist. This objection, I am convinced, is not strong. Although it must be conceded that the broad privilege of taking short courses would undoubtedly lead an increasing number of physicians to interest themselves in radiology and perhaps to employ it in their own work, I feel certain that, instead of limiting the field of the specialist, it would extend it. The more widespread the realization of the usefulness of different phases of radiology, the greater the likelihood that the real value of highly qualified specialists will receive the recognition it deserves. Certainly, it cannot be said that the short postgraduate courses in ophthalmology have lowered the level of ophthalmologic practice as a

---

* Read before the Annual Congress on Medical Education, Medical Licensure and Hospitals, Chicago, Feb. 16, 1932.

[1] Desjardins, A. U.: The Status of Radiology, J. A. M. A. **96**: 1749-1753 (May 23) 1931.

whole; on the contrary, it has led an increasing number of physicians to recognize the importance of high grade ophthalmology, and the status of this branch of medicine has risen as the number of qualified specialists has increased. To be sure, it would be fallacious to assume that this achievement has resulted from the provision of short postgraduate courses; the point is that such short courses do not appear to have acted as a deterring factor, and there are reasons for thinking that they have had an opposite effect. Therefore, the fear that short courses of instruction in radiology for graduate physicians may interfere with the general program of placing the postgraduate teaching and practice of radiology on a higher plane seems unwarranted.

Among the subjects in which short courses might well be provided are:

Physics of roentgen rays.
Physics of radium.
The quantitative and qualitative measurement of roentgen rays and radium.
Roentgenologic technic.
Roentgenologic interpretation.
Roentgenologic diagnosis of diseases of bones and joints.
Roentgenologic diagnosis of diseases of the respiratory tract.
Roentgenologic diagnosis of diseases of the gastro-intestinal tract.
Roentgenologic diagnosis of diseases of the urinary tract.
Roentgenologic localization of foreign bodies.
The newer methods of roentgenologic diagnosis.
The biologic principles of radiotherapy.
The technic of roentgen therapy.
The technic of radium therapy.

Physicians taking such courses should be entitled only to a certificate of attendance and should not be required to pass any examination, unless the number of short courses taken is sufficient to enable them to qualify as specialists. In this event, they should be allowed to take a comprehensive examination, and, if they succeed in passing it, they should be entitled to a certificate and to the title of specialist. The courses should be arranged so as to crowd as much information as possible in the time allowed and should consist of both didactic and laboratory exercises or practical work. The aim of the lectures should be to set forth principles and to explain their application, so that those who take such courses may be able to solve their own problems by analyzing the factors involved and applying fundamental laws. Neither didactic nor practical instruction alone can serve the purpose. Laboratory exercises should be chiefly in the form of demonstrations, because to expect the average short-course student to derive much information from being allowed to fuss and stew in a laboratory for two hours a day for six weeks would be likely to prove a delusion. Often it would only serve to waste the time of the student and of the instructor. In general, a well conducted demonstration would be much more effective. In certain courses, however, in which it is essential for the student to familiarize himself with technical procedures or with the operation of measuring or other instruments, individual practice under the supervision of the instructor is essential.

COMPREHENSIVE GRADUATE COURSE

The comprehensive course leading to a degree such as that of Master of Science in Radiology or Doctor of Radiology should be conceived along the broadest possible lines. It is difficult to see how anything like a thorough course of instruction can be compressed into less than three years. Any attempt to effect undue compression must necessarily result in sacrificing thoroughness and, therefore, quality.

To insure that candidates may be able to take full advantage of the course, they should be subjected to reasonably rigid requirements, as far as antecedent instruction or training is concerned. The privilege of registration should be restricted to graduates of class A schools and preference in selection should be given, or selection should be limited, to those who have had, as part of their premedical training, college courses in physics and biology or their equivalent. An internship of at least one year in a class A hospital should also be required as a preliminary to registration.

The first year of the graduate course should be devoted to anatomy, physiology and pathology and to the physical aspects of radiology. One half year of concentrated training in anatomy, physiology, pathologic anatomy (otherwise known as gross pathology) and microscopic pathology would provide the strongest possible foundation for both roentgenologic diagnosis and radiotherapy. A radiologist cannot possibly have too much knowledge of anatomy and pathology. Ability in roentgenologic interpretation depends in about equal measure on knowledge of anatomy and pathology, and these subjects are about equally important for roentgen and radium therapy. To meet the needs of roentgenologic diagnosis, instruction in anatomy should lay particular stress on landmarks and relations of special importance in roentgenology and on the developmental phases of bones. Physiology should be taught chiefly in the form of a review, but special attention should be given to the more significant radiologic considerations.

The second half of the first year should be given over to radiologic physics, instruction in which should include both didactic lectures and laboratory exercises. The lectures or conferences should be as practical as possible and should be planned so as to explain and demonstrate physical principles as they apply to different phases of radiology. As much as may be feasible, examples should be selected from material related to that subject, and demonstrations should be arranged in the same way. The object of the laboratory exercises should be to serve as additional demonstration of principles, to explain the construction and operation of apparatus, and to familiarize the student with physical methods and instruments for measuring electrical potential and resistance, the quality and quantity of roentgen rays, and all other measurable factors that enter into the scientific practice of radiology.

The second year should be fully taken up by diagnostic roentgenology. Not only should the students be taught how to interpret roentgenograms, but they should be required to spend a good part of their time in performing, under the guidance and supervision of qualified instructors, the numerous technical procedures incidental to the present-day practice of diagnostic roentgenology. To watch some one else and to do things oneself are two quite different things. The one may be a useful preliminary to the other, but in no way can the former be regarded as a substitute for the latter. One who has not become thoroughly familiar with every step of a procedure by actual experience can never be in a position to direct subordinates intelligently. By every possible means, therefore, students should be induced to regard themselves as working members of the department in which they are receiving instruction and should be made to feel some measure of responsibility for whatever work they may be engaged in. This is the only way by which any one can expect to become really proficient. Roentgenography and roentgenoscopy have become so important that familiarity with every phase of their utilization in the diagnosis of diseases of bones and joints, of the digestive, respiratory and urinary tracts, of the nervous system, and also for the recognition and localization of foreign bodies, requires a detailed knowledge of many methods and of the variations in technic by means of which maximal information can be elicited under different circumstances. To become proficient in every detail of roentgenologic diagnosis in one year does not allow any time for frivolity. The question is, is one year really sufficient? Certainly, it can be accomplished only by careful planning and correlation and by the utmost economy of time.

Perhaps the foregoing results can best be achieved by arranging for the students to concentrate their attention, for periods of two or three months, on the roentgenologic procedures involved in the diagnosis of lesions affecting each of the groups of structures or organs previously mentioned. However, a fixed schedule is out of the question, because considerable latitude must be allowed in adjusting the details of the scheme of instruction to the circumstances of the institution in which the course is given. Besides instruction and practical training in roentgenography and roentgenoscopy, the students should be taught the photographic and chemical aspects of roentgenography and the methods of protection required for the safe practice of radiology.

Throughout this part of the course it is desirable that contact with clinical medicine and surgery be maintained. In some institutions the diagnostic roentgenologist may be obliged to work with little knowledge of the clinical features of the cases examined. At best, this is to be regarded as an unfortunate necessity, but never should it be looked on as an ideal. On the contrary, the closer the relations between medical or surgical clinicians and the roentgenologist, and the more knowledge the latter may have concerning the cases he examines, the more valuable should be his opinion.

The third year should be given over to therapeutic radiology, including roentgen rays, radium and, if possible, ultraviolet radiation. The field of radiotherapy, once so restricted, is now rapidly extending, and every radiologist worthy of the name should receive as broad and as thorough training in the therapeutic as in the diagnostic aspect of this branch of medicine. The conspicuous and widespread lack of such training, and of the clinical and pathologic foundations on which it rests, are among the most glaring deficiencies of present-day American medicine. Owing to the general neglect of this phase of the subject, but chiefly because of the lack of qualified instructors, few institutions are now in position to undertake such teaching. If this deficiency is to be corrected, a beginning must be made. For a time it may even be necessary for two or more institutions to pool their facilities and personnel.

Students should be required to take an active part in the examination of patients, in outlining their treatment and in preparing patients for irradiation, as well as in the actual administration of the treatment. It should be quite feasible to arrange the work so that, without any transfer of responsibility from those on whom the professional and legal obligations actually devolve, the students may yet have an appreciable share in all phases of such treatment. Only through some such scheme can they be made to realize the significance of many details, careful consideration of which and attention to which spell the difference between superior and inferior treatment. Too often the medical side of radiotherapy is neglected and the physical aspects are overemphasized. Both should receive due consideration. Important as it is to know the quantity and quality of radiation most useful in dealing with different pathologic conditions, it is even more important to be able to recognize the disease at different stages, to ascertain the extent of the primary lesion and of secondary foci, to size up the general state of the patient, and to adjust the treatment accordingly. Needless to say, the instruction in therapeutic radiology must be delegated to instructors of broad medical and radiologic experience. It may be contended that the general clinical, pathologic, dermatologic, surgical, gynecologic and other aspects of radiotherapy should be presented by specialists in the respective branches. But considerable difficulty may be encountered in finding specialists who have had sufficient experience with the radiologic aspects of their subject to qualify them for the task. To mention another example, few pathologists, and only a slightly greater number of practicing radiologists, know much about the relative radiosensitiveness of different varieties of cells and tissues. To be sure, the subject is still comparatively new, but, unless a start is made, such knowledge as we possess will be slow to diffuse.

On the whole, the most feasible arrangement at the outset will probably be to delegate the general teaching of the subject to the most experienced and the best informed therapeutic radiologist available. He, in turn, should arrange to have those phases of the subject with which he is not sufficiently familiar presented by qualified specialists. The strictly radiologic teaching should be supplemented by lectures on related aspects of clinical medicine, surgery and dermatology. Here again the need of combined didactic and practical teaching must be emphasized. This can be accomplished by means of lectures, but another effective, supplementary method is that of conferences or seminars at which certain of the students present a general review of some phase of the subject, which is then discussed by the instructor and by the other students.

The scope of roentgen therapy is distinctly broader than that of radium therapy, in that a wider variety of cutaneous, inflammatory and neoplastic diseases are amenable to treatment with roentgen rays than with radium. It must not be inferred, however, that the former subject should be allowed a greater proportion of time than the latter. An approximately equal period should be allotted to the two subjects. The therapeutic use of radium involves physical, clinical and often surgical considerations, in which adequate knowledge, experience and judgment cannot be acquired hurriedly.

The program which I have ventured to outline would not be complete without the additional condition that, as part of his training, each graduate student should be required to undertake a piece of research on some phase of diagnostic or therapeutic radiology and to prepare a report or thesis based on such work. It is true that some, who may be brilliant in the practical aspects of radiology, may not shine as investigators. The value of the research requirement does not lie so much in the actual results obtained as in making the student realize the importance of careful work and in the discipline which may cause him to realize that, even after an extensive course of study, he does not know everything.

I am aware that such a sketchy outline may be unsatisfactory and that some would undoubtedly prefer a more detailed plan. I have deliberately avoided this, however, because the conditions at each institution, and the personnel and facilities available, vary so much that the details of any scheme of instruction must be worked out by those who are familiar with the requirements on the one hand and with the local conditions on the other.

THE TEACHING OF RADIOLOGY TO INTERNS *

JAMES T. CASE, M.D.
CHICAGO

The average physician cannot boast of great familiarity with the conduct or interpretation of roentgen examinations, or of adequate comprehension of the possibilities of diagnostic aid to be obtained from x-ray studies. His contact with x-ray problems consists in the main of emergency cases in which fractures or dislocations are suspected, and occasional reference of cases to x-ray laboratories for a "picture" of the lungs, stomach or urinary tract. He has not appreciated that, in addition to skeletal diseases and injuries, roentgen studies may be applied with advantage to nearly all visceral disorders, including many diseases of the nervous system. He does not stop to realize that examination with the x-rays is much more complicated than the simple taking of a "picture": that it is really no more a simple laboratory procedure than an ophthalmic examination or a urinary tract examination or a gynecologic study, and that a clinical knowledge of the conditions entering into his problems is a necessary part of the preparation of the radiologist. The "picture" of the stomach turns out to comprise a careful fluoroscopic investigation supplemented by anywhere from three to a dozen or more roentgenograms in various positions and under various circumstances according to the individual case. The "picture" of the lungs proves to be much more involved, the patient requiring fluoroscopic study in the erect position at various angles, with films to record whatever may be questionable or of especial interest; and sometimes it is advisable to make a screen study of the patient in the horizontal, prone, supine or lateral position, and to record the results with the necessary films. All of which sounds, and in actuality is, much more complicated than the simple word "picture" would imply, and yet to the layman who hears the x-ray study spoken of as a "picture," the physician's use of this term only serves to strengthen his impression that a roentgen examination is nothing more than some sort of glorified photography.

The remedy lies in some measure in the widening of the horizon of the general practitioner in relation to x-ray matters by having the radiologists of the country enter into a campaign of education through staff meetings, county society and other medical meetings. To a certain degree, perhaps as rapidly as possible, this is being carried on at the present time; but the logical and most important step is to carry this education to the young graduates of medical schools while they are in their intern year.

Medical students receive a certain amount of instruction in radiology, mostly in connection with x-ray investigations made in relation to the various patients with whom they come in contact during their clerkships and clinics. In addition, most medical school curriculums now include required didactic courses in roentgenology, usually in the senior year, and in many there are well trained roentgenologists who carry on excellent systematic courses of lectures and demonstrations to the students during both the junior and the senior years. Many schools make it possible for their students during their senior year to serve a clerkship in the x-ray department. Thus, when the graduate of today comes to the hospital as intern he already possesses a good foundation for further elaboration of his knowledge of roentgenology.

Statistical data from 619 hospitals approved for interns indicate that more than 80 per cent offer instruction in x-ray work. In some, provision is made for the rotation of the interns to include a brief service in the roentgen department, and in some of the larger hospitals there is a special x-ray internship. In others, occasional lectures are arranged to be given by the members of the staff of the roentgen department so that the interns may have more or less systematic instruction in roentgen diagnostics and therapy. In most hospitals, however, observation leads me to believe that the x-ray instruction given interns is desultory and not under definite check. The idea seems to be that the intern may absorb his knowledge of radiology while making rounds with the attending physicians and surgeons. In small institutions this is perhaps a necessary procedure, but in hospitals where the services of a trained roentgenologist are available it would be well for the interns to get from him also his slant on the meaning of the roentgen examination. The attending staff has a duty and a privilege in collating the roentgen observations with the other clinical and laboratory aspects of each case; whereas the roentgenologist, no matter how familiar he may be with the clinical and laboratory observations in a case, must not read into his roentgenologic interpretation more than can be supported by the x-ray evidence. It is well for him to know as much as possible about each case, the more the better, but he should not put into writing as a part of the x-ray report any statement which cannot be substantiated by the x-ray evidence.

PROGRAM OF INSTRUCTION

It is evidently quite necessary, if interns are to be given x-ray instruction, to formulate a definite program which can be followed out. Let me consider some of the things I believe it essential for an intern to learn about the x-rays. Naturally, the extent to which this ideal can be carried out depends on the size of the hospital.

1. *The nature and origin of x-rays and of secondary radiation, and the physical and biologic laws that apply to them.* This may be accomplished by reading textbooks, and it may have been done by some of the interns, but a systematic review should be made of the subject. Only by appreciating the physical facts will the intern ever learn to take care of himself and his patients during roentgenologic investigations and therapy. He should be taught the necessity of constant protection by lead-rubber aprons and gloves; to conduct roentgen examinations with expedition; to realize that proper filters must be kept in place between the source of the rays and the patient, whether for therapy or for examination, and that that most inexorable of laws, the inverse square law, applies to all radiation (including

---

* Read before the Annual Congress on Medical Education, Medical Licensure and Hospitals, Chicago, Feb. 16, 1932.

radium and ultraviolet rays). He should learn that the patient becomes a potent source of secondary radiation against which protection must be provided.

2. *The scope of roentgen examinations.* In his daily work the intern learns the general applicability of the roentgen rays to diagnosis, but the refinements of x-ray diagnosis should be systematically brought to his attention by didactic work. There are conditions not encountered in daily work in which the average physician will not think of a roentgen examination; for instance, acute intestinal obstruction, subphrenic abscess, pulmonary and pleural abscesses, perirenal abscess, certain abdominal abscesses, the measurement of the size and the position of certain viscera such as the liver and spleen, and the application of opaque oils and other opaque mediums to the study of the sinuses and fistulas as well as certain organs into which such opaque oils may be introduced. The localization of foreign bodies is a field in which most physicians do not know (or else have forgotten) the value of the x-rays. Physicians with experience on the front during the war had brought home to them repeatedly the value of the x-rays in localizing foreign bodies of all kinds, special emphasis being placed on fluoroscopic methods; yet how few seem to remember at this short interval since the war the efficiency and the speed of the fluoroscopic methods of routine use in war hospitals during hostilities. Peace time studies have added nonopaque foreign bodies in the respiratory tract to the opaque foreign bodies detectable with the roentgen rays. Naturally the intern, even in his student days, became familiar with the scope of the roentgen study of the gastro-intestinal tract, the urinary tract, the lungs and bronchi, the heart and great vessels, and the skeletal injuries and diseases. It is important that in all autopsy and staff conference discussions the roentgen observations should be presented by the radiologic department and carefully correlated with the clinical and autopsy aspects of each case. It is a practice in one hospital, at least, to present at the autopsy room a roentgenogram of the chest, made post mortem, to bring further down to date the x-ray data on the thorax.

3. *Fluoroscopic control of the reduction of fractures and dislocations and in the removal of foreign bodies.* Some of the larger hospitals are equipped for biplane fluoroscopy for use during the setting of fractures and the reduction of dislocations, but the very accessibility of such apparatus may tend to relax one's vigilance against damage by the x-rays to the patient and staff. Every year new cases are brought to attention in which irreparable damage has resulted to physicians from injudicious fluoroscopy. When special apparatus is not provided for such work, improvisation can be made in the roentgen department or a portable x-ray instrument and a hand fluoroscope may be carried to the operating room, under which circumstances the dangers of damage by the x-rays to the staff is greatly increased, to say nothing of danger from possible explosion from unwise choice of anesthetic agent to use under such circumstances. These precautions are all the more important if it is sought to use the roentgen aid in the extraction of an opaque foreign body. Here again one seems to see very little effort to use the fluoroscopic aid so widely taught in military surgery. Time and again one sees surgeons attempting the removal of superficially located foreign bodies in the good light of the operating room when, by the aid of the fluoroscope and a proper technic of protection against surgical contamination and roentgen damage, the offending substance may be extracted with great saving of time and no danger from the x-rays.

4. *Roentgen interpretation.* To develop skill in reading roentgenograms and in translating the appearances made manifest by fluoroscopy there must be opportunity for observation of and participation in fluoroscopic and x-ray film examinations, and for sharing in the conference at which the roentgenologist puts together into the written report the x-ray evidence shown by films and screen. To make this of teaching value, it is important that the roentgen department be furnished with a statement of the problem in each case referred for examination. It is not enough to refer the patient merely for an examination of such and such part; the examination desired should be stated, but, most important of all, the problem should be stated clearly. The referring physician had some reason for sending the patient for examination in the roentgen department; what was that reason? A tentative diagnosis would be ideal, but practically it seems impossible to get the cooperation of staff members to that extent. It is possible to insist on knowing the question that was in the referring physician's mind when he wrote the requisition and he should take the time and trouble to state his problem briefly.

5. *Roentgen terminology.* Terminology is of importance in the instruction of interns. It is difficult to change the habits of a lifetime and, on the other hand, it is relatively easy to instruct young people just entering their practical experience. To a man who has all his life spoken of roentgen examinations as "having a picture taken," and who has been guilty of sending his patients into the x-ray department for an "x-ray picture of the gastro-intestinal tract," an "x-ray picture of the lungs," and of this, that and the other thing, it is useless to talk about terminology. But the younger men are susceptible to persuasion and rule in this matter, especially when reason is used in talking with them. There is a certain dignity which belongs to all branches of the medical profession, and it is well to maintain that dignity. The surgeon does not speak of making such and such a "gash" or "slash" to "dig out" the appendix; that would be exceedingly undignified. He makes such and such an "incision" to "resect" the appendix. One does not "dig out" the prostate through a low belly "slash"; he "enucleates" the prostatic tumor through a "suprapubic incision." Just so, in roentgen terminology it is possible with a little care to school oneself to dignified language and to speak of x-ray films, x-ray examination and x-ray study if one is determined that his tongue cannot negotiate the more cumbersome "roentgenogram" or "roentgen study." One of my dear friends protested that he could not curl his tongue around "roentgenogram," yet within two or three minutes he was talking about a nice case of urethral obstruction in which he performed a "ureteromeatotomy"! Proper terminology aids materially in the collection of fees that are necessary to carry on x-ray work adequately. The American Medical Association has published an acceptable list of radiologic terms.

6. *Therapy.* The field of roentgen therapy is so complicated that it is to be doubted whether more can be done in the way of instruction during the intern year than to teach the general principles of treatment, the selection of cases, the realization that it is possible to make accurate dosage, and the limitations of the method.

Circumstances will determine how far such a program can be carried out in the individual hospital. In large hospitals, with internships of from eighteen months to two years, it is quite reasonable that a portion of this time be given to the roentgenologic department, each intern spending a while in that department as a participating assistant. Such a stay should be for not less than two months, and three would be better. The practice of assigning an intern to the x-ray department instead of a place on a rotating service should be condemned; no fellow in the roentgen department should be accepted until after having served his regular internship, and preferably after a few years of general practice. Failure to observe this precaution results in unbalanced training, which soon becomes evident in the practical work of the fellow.

In some hospitals the interpretation is done at the same time during which the members of the attending staff are making their rounds, so that it is difficult for the interns to participate in the reading of the roentgen examination. In such cases it is feasible to arrange a certain hour at the close of the forenoon or at the end of the day for revision of some of the more interesting of the x-ray cases of the day. It is also possible for the staff to arrange that the roentgenologist shall give a series of systematic lectures and demonstrations covering the x-ray instruction deemed necessary.

Much good will have been accomplished if the intern on leaving the hospital can carry with him a thorough appreciation of the scope and limitations of the roentgen examination in various disease conditions, its value and dangers in the control of fracture and foreign body work, and its place with radium in the treatment of many benign lesions as well as in the management of malignant disease.

180 North Michigan Avenue.

TEACHING OF RADIOLOGY TO UNDERGRADUATE STUDENTS *

HENRY K. PANCOAST, M.D.
PHILADELPHIA

Radiology occupies rather a unique position as a subject for teaching to undergraduate medical students. It is a new medical specialty. Its diagnostic and therapeutic applications have grown at a tremendous rate and have become unusually widespread. While it is more or less intimately concerned in every branch of medicine, its development has been left largely in the hands of a comparatively few medical men, assisted in a great measure by physicists and manufacturers of equipment. Its development and its position as a specialty have been taken largely for granted by the greater part of the medical profession. Comparatively few students or recent graduates expect to take it up as a specialty or even to practice it directly in a smaller way, although it must serve all of them. For these reasons, little earnest thought has been given to radiology from the standpoint of undergraduate teaching, aside from the desire and pride on the part of radiologists to further the interests of their specialty. The latter attitude is but natural, for, as Barclay[1] states, "when a teacher is placed in charge of a special department, it must be his aim and object to further its interests."

REASONS FOR TEACHING UNDERGRADUATES RADIOLOGY

While radiologic specialists are constantly urging their claims for teaching privileges, the question frequently arises no doubt in the minds of medical faculties as to why any extended instruction in radiology to undergraduates is necessary. This can be answered by numerous reasons, which, because of their multiplicity and complexity, require enumeration:

1. The intern and the comparatively inexperienced young physician should know something about a means of diagnosis and treatment which either must call on frequently for assistance. Perhaps this appeals to me more than it does to some of the younger generation because my student, intern and early medical experience was gained in the first years of roentgen diagnosis and treatment, when there was no teaching of any kind on the subject. Impressions of roentgenograms and the reasons for therapeutic actions and their effects were as vague as they possibly could be on any subject pertaining to medicine. When, as an intern, I was shown the roentgenogram of a chest, no mental impression whatever was made of the patient's condition because of an utter lack of knowledge of anatomy and pathology as they might be expressed by roentgenographic shadows and appearances. The intern of the present day, however, realizes something of the value of roentgenologic studies because he has been taught something about the subject. He has some understanding of normal and pathologic appearances when they are demonstrated to him. He even learns to interpret abnormalities for himself.

2. Today one seldom sees a clinical journal that does not contain important references to roentgen diagnosis or therapy. Must the intern or the young physician skip over these references without a proper understanding of them?

3. Roentgen diagnosis now is applicable to every branch or specialty in medicine. In surgery, every fracture and dislocation must be examined, not only because of the aid given to the surgeon and patient but also because of almost a legal requirement. The roentgenogram is the most satisfactory and safest means of diagnosing and studying bone diseases and tumors in most instances. Nearly all surgical gastro-intestinal lesions are diagnosed or confirmed by roentgenologic study. The detection or confirmation of a large number of urologic conditions depends on roentgenologic assistance, often aided by intravenous or retrograde urography. Diseases of the gallbladder, intracranial lesions, many intrathoracic conditions and a host of others require study by this method. In connection with internal medicine, the radiologist has to search for foci of infection in the teeth and sinuses. Practically all intrathoracic conditions require more or less roentgenologic study. The digestive tract and the gallbladder constitute a wide field for investigation. In addition, there are bone, joint, soft tissue and many other conditions for which examinations frequently must be made. The pediatrician frequently calls for assistance in examinations of the sinuses, mastoids, pharynx, chest and bones. The orthopedist would be lost without roentgenologic aid. The bronchoscopist could do but little without it. The laryngologist requires it constantly and the neurologist very frequently. Thus, *radiology is practically a specialty within specialties.*

4. The student should be taught the value of, and in many instances the absolute necessity for, roentgenologic diagnosis as well as its limitations, for he is

* Read before the Annual Congress on Medical Education, Medical Licensure and Hospitals, Chicago, Feb. 16, 1932.

* From the Radiological Clinic of the Medical School of the University of Pennsylvania and the University Hospital, Philadelphia.

[1] Barclay, A. E.: The Dangers of Specialization in Medicine, the thirteenth Silvanus Thompson Memorial Lecture, Brit. J. Radiol. 4:60-82 (Feb.) 1931.

soon to become an intern. As such, he is in many instances the one to request roentgen examinations, until, perhaps, the radiologist has reason to mistrust his judgment and insists on a higher authority.

5. The student of today should be taught not to depend on roentgenologic aid at the expense of other and older diagnostic methods. He must learn to realize that such studies are expensive procedures for patients and institutions and should not be employed unnecessarily. On one occasion, an intern requested studies on a single patient in a ward which would have cost the institution over $70 had they been carried out. A large part of this general examination was found to be entirely unnecessary.

6. There is a tremendous amount of mediocre roentgenologic work being done today by untrained and inexperienced men, and much of it is practically valueless and even misleading. The student and, later, the intern should be taught to realize this, so that when they enter into practice they may be able to judge what is dependable and what is not. Nevertheless, one should not be too hasty in judgment of diagnostic ability on the basis of the appearance of roentgenograms, for they may have been made under unusual and difficult circumstances beyond control if poor, or, on the other hand, some men can produce excellent technical results without having the ability of correct interpretation.

7. To establish the fitness of the young practitioner for such judgment and understanding as have been specified requires that instruction of some kind should have been instituted during his student days, whereby he could have gained some knowledge of normal roentgenographic appearances, their variations within normal limits, and the modifications produced by pathologic processes. By the time of his graduation and the beginning of his internship he should be able to understand the principles of interpretation of living pathologic conditions in roentgenologic terms. The internship would then be the time for him to gain what is needed in the way of experience.

8. Roentgenology is largely but not entirely in the hands of the medical profession today. Whether it will eventually fall more and more into the hands of commercial enterprises outside of institutions depends almost entirely on the proper teaching of the younger members of the profession of the interrelation of radiology with the other branches or specialties of medicine. There is a growing tendency, apparently the world over, in the direction of commercialism, even with the vicious habit of fee splitting. Lack of oversight in this particular line of work only serves to encourage similar proclivities in others. Haenisch[2] of Hamburg, in a recent memorial address, when commenting on the misfortunes arising from the rapid expansion of radiology when it lacked the cooperation of other specialties, made the following statement:

> The harm, however, which resulted from a too rapid expansion of the art and the consequent faulty, insufficiently prepared training was not the worst. This could, if the will were present, be minimized or even eliminated. Much more disastrous was the fact that the incompetent and dishonest elements grasped this specialty. These, in some instances, were unscrupulous physicians who were guided merely by the expected pecuniary advantages and who, unhampered by clinical and roentgenological knowledge and experience, "sold x-ray pictures," paying the referring physician rebates or commissions. . . . In other instances laymen, with or without connivance of dishonest physicians, saw in the purchase of x-ray apparatus a get rich quick scheme at the expense of innocent patients.

These practices are all too common, and their elimination must be a cooperative process, and the warning and the education cannot come too early.

9. Radiation therapy has a large share of importance in the treatment of neoplastic disease and many other pathologic conditions. Today, operative surgery, electrothermic procedures and the use of roentgen rays and radium are the only approved methods of dealing with cancer, which is one of the most important conditions with which we have to deal in these modern medical times, because it is second in mortality rate among adult diseases. The greatest efforts are being made by interested medical bodies to teach the public and, still more important, the medical profession, the importance of early diagnosis and proper treatment. It is generally agreed by these bodies that the proper time to *begin* this instruction is in the undergraduate medical schools. The teaching is preferably to be carried out by cancer clinic groups, but in lieu of this it must emanate largely from the surgical, medical and radiologic groups. Many of the unethical and unscientific methods of treating cancer could not flourish to the extent to which they do today did they not receive encouragement from men who have not been properly taught. Irradiation is a part of the therapeutic armamentarium of the dermatologist, and the student should be able to understand why it is used on the basis of biologic effects.

10. The dangers from excessive x-ray exposure should be understood, especially as they may be experienced in roentgenography and fluoroscopy for various purposes. Radiologists are frequently embarassed by the lack of knowledge of these dangers on the part of the medical profession in general.

METHODS OF TEACHING

The reasons so far enumerated would seem to constitute ample justification for instruction in radiology during the undergraduate and intern periods. The latter is an ideal opportunity, but this aspect of the teaching problem will not be considered here. Fortunately, intern instruction is prescribed by medical boards in many states. My only suggestion in this connection is an insistence that the groundwork should begin during the undergraduate period. The next arguments are over the time, the place and the method. Barclay states: "It is quite true that the overburdening and censequent extension of the medical curriculum is due to the increase in specialization. . . . The student of today has a far greater load of learning to cram into his head than he had a few years back, far more than he can ever hope to remember." The method of general didactic class instruction in radiology as carried out in most institutions in the past has been a failure in many respects. It has certainly not accomplished the desired results, and the only service it fulfils is to give the class as a whole some idea of the scope of radiology, and this is not sufficient compensation for the time and effort. Didactic teaching by lectures to hitherto untaught students means in part the showing of series after series of roentgenograms or lantern slides representing pathologic conditions which the student sees with little or no understanding of their import. Even were he shown the normal first, he cannot correlate that appearance with the structures of the human body represented because he has never been taught to do so. The futility is realized when the teacher reads examination papers or asks even the most practical questions at the end of the period. A few exceptional students may have grasped the subject, but the large majority have not. Didactic lectures are better adapted to graduate students who have received sufficient ground work in the subject to enable them to absorb and assimilate that kind of instruction. Didactic teaching of radiology had its inception largely in the fact that no textbooks were procurable on the subject, whereas this method has gradually declined in other specialties as suitable collateral textbooks have become available.

---

[2] Haenisch, G. F.: Roentgenology as a Specialty, the Caldwell Lecture, Am. J. Roentgenol. **26**: 821-833 (Dec.) 1931.

Human psychology requires that the reasons for certain results must be explained if these results are to be understood and are to make any permanent impressions on memory. Hence, if the student knows why and how roentgenographic and fluoroscopic appearances are brought about or biologic effects are produced, his mind will be more receptive in the way of interpretation of shadows of the body structures and the indications for treatment by irradiation and the results obtained thereby. Therefore, in teaching radiology it is necessary to preface the practical aspect of the subject by a short course of instruction in physics. This must be didactic, but it should be made as elementary as possible and, at the same time, interesting. It should have been taught as a premedical subject, but this seems seldom to have been done, or, at least, not in a manner capable of impressing the students in a way a teacher of radiology would desire. The most appropriate time for it, or, at least, to review the necessary part of the subject of physics, if it must be included in the undergraduate medical curriculum, would seem to be during the first year. Then there is more time for it and it can precede any practical teaching. Surely the medical practitioner should know something about the physics pertaining to x-rays and radium and the physical problems involved in their application. It need be but a small percentage of what the radiologist must know and even make use of every day. The physician should be able to talk intelligently with his patients about what he orders for them, if nothing more. How many physicians know just why irradiation is used in cancer or the difference between radium and its emanation or the similarity in effects of roentgen rays and radium? The utter lack of knowledge by physicians of the most elementary facts concerning radiology is often ludicrous and, at times, even embarrassing to the radiologist. Their utter ignorance of nomenclature is all too apparent to editors of journals. The teaching of all the physics a student requires should take but a few hours.

In the teaching of radiology, all selfish motives of the radiologist should be excluded and he should formulate his plans in such a manner that the instruction may aid that of other subjects rather than take time away from them. Barclay says: "In teaching the radiological aspect of anatomy and physiology to men . . . I find that nearly all of them have forgotten these subjects to an astonishing extent. Surely there must be something radically wrong that this should be the case. I believe the trouble lies in the fact that these have become specialist subjects, taught by specialists, in departments that are separated from those in which the practice of medicine goes on." If this is true, as I believe it to be, at least to a considerable extent, is it not possible that the teaching of radiology might serve as a liaison between the clinical and the preclinical branches? As a matter of fact, such a purpose would seem to be a direct outcome of many proposed modern methods of teaching radiology.

When the internist presents a didactic or clinical lecture to his students, the latter have been prepared in anatomy, physiology, pathology, materia medica, applied therapeutics and physical diagnosis for a better understanding of the clinical subject under discussion. This progression of teaching has been worked out through long years of experience. Somewhat similar methods of progression would seem to be applicable to the teaching of radiology. Instead of a curriculum which prescribes a course consisting of a series of didactic lectures on the general subject, suppose we substitute one in which the roentgenologic aspect of anatomy, physiology and pathology in the living subject is considered in connection with the teaching of those branches and, later on, with the diagnosis of living pathology in the clinical branches.

One of the greatest misfortunes of the early radiologists was their enforced neglect of the study of the normal. When they started their work they were obliged to delve immediately into the abnormal without an adequate knowledge of what was normal. Fortunately this has been realized and has been corrected to a great extent, but not entirely. Inadequately trained individuals are often prone to interpret normal variations as evidences of disease because of their lack of knowledge of roentgenologic anatomy, physiology and pathology. One of the most flagrant examples of this was the one time popular peribronchial tuberculosis. Unfortunately, too many of us were culpable in this error. Unfortunately, the assertions of insufficiently trained radiologists have been accepted by unsuspecting clinicians who did not realize the absolute necessity for a proper anatomic and pathologic knowledge in roentgenographic interpretation. As a result, men by the wholesale were kept out or put out of the military services or were granted undeserved compensation because of alleged tuberculosis without any true pathologic basis in roentgenograms. The radiologists of the future must be properly trained on the basis of our experiences of the past. Why should not the proper form of instruction be given, though on a much smaller scale, of course, to the physicians who must, in the end, be the real judges of the fitness of radiologists when the health of their patients is at stake?

RELATION TO OTHER BRANCHES

Anatomy, one of the first basic branches, is a study of the normal. It is not a subject to be "crammed" and all too soon forgotten. Whether it is covered during the first year or, better, during the first two years, that is the appropriate time for demonstrations of normal living anatomy as depicted on roentgenograms or by fluoroscope. This could be done all at one time, but preferably, as each part of the body is taught, the normal roentgenographic appearances could be demonstrated. This would include the skeleton, with adult appearances, and also a short demonstration of epiphyseal development, with an explanation of what the roentgenographic appearances mean at different ages. I never knew just what an epiphyseal separation really was until I saw it demonstrated roentgenographically in intern days. The relations of the bones at the various joints and in the spine should be described anatomically and then roentgenographically. The student seems utterly at sea when shown roentgenograms of sinusitis, mastoiditis, pituitary tumors and the pathologic conditions demonstrated by ventriculograms and encephalograms. Surely, when the student is taught the anatomy of the head and brain he could be made to understand the roentgenographic appearances of the paranasal sinuses, mastoid cells, sella turcica and cerebral ventricles. I always considered the latter and the circulation of the cerebrospinal fluid things to be learned and then forgotten until the advent of ventriculography and encephalography. Surely, typical normal encephalograms and ventriculograms could be advantageously used for demonstration purposes when these structures are considered anatomically. The entire digestive tract could be demonstrated roentgenologically as the anatomy instruction proceeds. The student should be taught just how the radiologist sees it as a muscular tube with potential lumen when empty and with invisible walls, but only as a lumen shadow when filled with opaque contents. Later on he will be better able to understand how pathologic conditions will affect this lumen shadow. The kidneys, ureters and bladder can be demonstrated by normal urograms after retrograde or intravenous injections of opaque substances. Normal gallbladder demonstrations will be in order, with a few facts explaining the method of filling by the dye, although this would come more under physiology. In connection with the thoracic contents, the heart and vessel shadows should be demonstrated. Diaphragmatic excursion and cardiac pulsation should be reserved for section fluoroscopy. Group demonstrations would always be desirable for all this teaching, especially to permit of questions being asked by the students, but, if not feasible, much improvement in the present teaching plan could be made possible even by the usual class demonstrations of the various parts as the anatomic instruction proceeds. In all these demonstrations the student will be better able to understand why he sees the shadows of the structures shown if he has just received his preliminary short course in physics. Needless to state, these anatomic demonstrations should precede any attempt to teach roentgenographic pathology. All this anatomic teaching should be carried out in the medical department.

The course in physiology is an important teaching opportunity for roentgenology. Many of the important and really practical physiologic facts have been determined by fluoroscopic and roentgenographic observations, especially in connection with the digestive and urinary tracts. A number of the older beliefs have been entirely changed, and yet it is surprising how slow physiologists have been in appropriating this means of gaining knowledge, and it is inconceivable how known and recognized roentgenologic discoveries have failed to appear in textbooks. Barclay calls attention to the persistence of the Alexis St. Martin observations in modern print when they are manifestly absurd in the light of our present knowledge of gastric motility. How many physiologists teach that the stomach cannot empty properly when the individual lies on his left side; that peristalsis is a mixing mechanism in the stomach but largely propulsive in the intestine; that it and general gastric tonicity together are responsible for motility; that the shape and position of the stomach depend on the build of the individual, tonicity and the amount of contents; that there are such conditions as gastric compensation and decompensation; that pyloric spasm is induced by heavy exercise after a meal, mental fatigue and headache, and that most or all of these phenomena can be demonstrated easily by the fluoroscope? Students seldom know the differences in motility of the upper and lower small intestine and of the mass type of peristaltic phenomena of the colon, and yet these are all practical facts. Several men have followed Cannon in this line of investigation, but many have not. During recent studies of the normal swallowing act I have been surprised at the inaccuracies of physiologic statements concerning this mechanism or the lack of them. Barclay[3] has been struck by similar observations. It is almost inconceivable how the radiologist could have progressed as he has without the help of the physiologist, but it is conceivable that progress could have been more rapid with the physiologist's cooperation in the early days. It is quite easy to demonstrate how coarse foods remain much longer in the stomach than semiliquid suspensions of finer food particles. This is an example of information that would be of value in connection with later clinical teaching. Demonstrations of barium enemas would be most instructive even if made but once to each student. The pulsations of the heart and vessels, the normal movements of the diaphragm domes and the costal movements with respiration would be so spectacular as to be easily remembered by the student. Naturally, all such demonstrations could be witnessed by only small groups of students at a time. The dangers of exposure should be considered carefully as they apply to both observers and subject, and all such demonstrations should be under the direction of the department of radiology.

Pathology is the next branch by which the student should be helped toward an understanding of the practical aspect of roentgenology. Any teaching along this line should follow that of the normal, as already described. Pathologic anatomy in conjunction with roentgenology should be taught first, from the standpoint of the manner in which the disease affects the structure directly and grossly, and, secondly, as it alters function, because roentgenology is essentially a study of pathology in the living subject and thus differs from morbid anatomy as it is usually understood. The student should learn the actual gross and microscopic pathology first and then be taught to apply that knowledge to roentgenographic and even fluoroscopic appearances, just as the trained roentgenologist has to do every time he attempts to interpret evidences of disease in his roentgenograms or by roentgenoscope. The later didactic course in radiology will serve to show that when two or more pathologic processes present similar or indistinguishable appearances the clinical aspect of the case at hand, that is, history and clinical observations, must be carefully considered in the rendering of a correct interpretation by the process of exclusion. It is probable that, when the student has become familiar with normal roentgenographic appearances, typical roentgenograms of pathologic conditions will serve the pathologist well for demonstration purposes, not only when teaching from gross specimens, but also in general didactic instruction in various pathologic conditions. Needless to say, a normal roentgenogram of the structure should always accompany that of the pathologic condition under discussion, as, for example, cancer or ulcer of the stomach, intestinal neoplasms, bone tumors, aneurysms, heart conditions and many other intrathoracic lesions. It would seem almost if not quite as important to teach roentgen appearances in pathology as it is the histologic pictures of the processes. The roentgenograms of the patient should always be on display in the autopsy room, especially when students are present.

---

[3] Barclay, A. E.: The Normal Mechanism of Swallowing, Proc. Staff Meet., Mayo Clin. 5:251-257 (Sept. 10) 1930; Brit. J. Radiol. 3:534-546 (Dec.) 1930.

PLACE IN CURRICULUM

The question naturally arises as to how all this instruction is to be carried out in connection with the preclinical branches, and especially in a minimum of time in an already overcrowded curriculum. The time factor in the problem may be disposed of first. All the demonstrations mentioned would be of comparatively short duration and form really a part of the teaching of the branch in which they are included. Many of them would lead to a better understanding of the subject at hand, especially from the practical point of view. I believe that the results obtained would amply pay for any extra time consumed.

It would seem preferable for all this preclinical as well as subsequent instruction to be under the direction of the professor of radiology, and for the teaching or demonstrations in each branch to be arranged through agreeable cooperation with the professor in each. There could be one fully equipped roentgenologic department in the medical school, with a well trained technician in charge who could handle all demonstrations and also take charge of all experimental work, as in research surgery, physiology, anatomy, pharmacology and other branches requiring it. This technician would not be a teacher. There are two ways in which roentgenologic teaching could be carried out. The first would be directly by a representative of the department of radiology. The radiologic staff in a teaching institution and hospital must, of necessity, in these days, be a large one. There must be a professor at the head and at least one or two associates. The assistants are frequently two to three year fellowship men, who are to become the trained radiologists of the future. They usually have minor faculty appointments. Technicians must look after all the details of purely technical work. One or more of the associates or fellowship men could be appointed to look after all the details of the instruction in the preclinical branches. The other plan would be to place this instruction in the hands of trained and competent members of the staffs of the branches, but with the department of radiology having a cooperative oversight. A combination of the two plans might be found advantageous. Decentralization of radiology is usually not a successful venture in the long run. It is a duplication of effort and is expensive and is not conducive to the best interests of teaching in general. It leads to a one track mind, whether applied to anatomy, physiology or clinical subspecialties, and fails to preserve the active spirit of cooperation so essential to the perfect teaching machine. The trained and experienced general radiologist is in a better position to see how the teaching in connection with all the branches can be best correlated. Clinical radiology is not laboratory work as we usually understand it. The trained radiologist must have a far wider vision than any laboratory chief can possible have.

In the third year, the student should be taught to correlate his knowledge of anatomy, physiology and pathology in a clinical application. The instruction should also be in the nature of a review, which intensifies the mental impression that may have been made previously. After such preclinical teaching as has been outlined there should be a striking difference in the student's receptivity to the clinical application of roentgenology compared to that which is possible when the attempt is made to teach him pathologic roentgenology only at this time, and without any preliminary introduction. The third year instruction under the radiologic staff, who can best correlate previous, present and future teaching, should cover a period of from sixteen to eighteen weeks during the last half of the year, with a weekly demonstration lecture. Each one should be elementary and based only on typical pathologic cases or examples. All exceptional and confusing cases should be absolutely excluded, and as few illustrative ones used as possible. Continuous didactic lectures illustrated by numerous films or slides shown in rapid succession make but little mental impression on the student, who is still very much a novice. An ideal way would be to divide the class into small sections for demonstration purposes, with each member of the staff teaching a small group simultaneously. Few institutions are equipped to do this, however. While actual didactic lectures should be avoided as much as possible, a few of them are necessary, especially in connection with radiation therapy, which is preferably a fourth year subject, however.

In the fourth year, roentgenology and clinical medicine and surgery and the special branches should be still further correlated. The plan we have followed for a number of years has worked out very satisfactorily. A class section of about twenty students spends an hour a week for six to eight weeks in a medical roentgenologic conference in which the director or professor of radiology is the leader and with the medical staff in attendance. Individual cases with which the students are familiar are discussed from the standpoint of history and clinical observations by the medical staff. The roentgenograms are then demonstrated and the roentgenologic deductions presented. The students are requested from time to time to attempt roentgenographic interpretations and are urged to ask questions.

Similar conferences are held weekly on surgical cases, with the surgical staff in attendance. After the roentgenologic deductions have been made, the surgeon in charge of the case in question briefly reviews the operation and gives the operative observations. These conferences last throughout the fourth year, so that each student has from twelve to sixteen hours of instruction. A similar plan is carried out with the pediatric staff, although student attendance is optional.

In addition to this, clinical medicine and surgery, and even some of the other specialties, should be taught with the use of roentgenologic data from roentgenograms as a part of the clinical picture of each case under discussion. Probably the subject of fractures is universally taught in this manner. The student will have a much better understanding of what the roentgenograms are intended to convey if he has had such preliminary training as has been outlined. In more or less didactic teaching of clinical subjects, roentgenograms of typical cases might well be shown, with normal roentgenograms for comparison, as a part of the clinical picture of each disease.

As has been previously stated, the preferable method of teaching radiation therapy would be through the agency of a cancer clinic group. The student should be taught unbiased views in regard to the indications and limitations of radium, roentgen rays, surgery and electrothermic methods. He then understands the necessity for early diagnosis and is prepared to go out and choose between accepted and unethical and unscientific methods of treatment.

The foregoing recommendations prescribe what would seem to be an ideal method of teaching radiology to undergraduate medical students and its correlation in a practical way with preclinical and clinical specialties. They are not entirely personal views but include also the ideas and even the practices of many teachers of radiology. They are offered for the purpose of general consideration with the hope that they may assist in the betterment of at least a small part of the medical curriculum.

CHRONIC INTERMITTENT DUODENAL OBSTRUCTION *

HOWARD F. SHATTUCK, M.D.
Attending Physician, New York Post-Graduate Hospital
AND
HARRY M. IMBODEN, M.D.
Professor of Roentgenology, Cornell University Medical College
NEW YORK

Chronic intermittent duodenal obstruction or ileus has attracted increasing attention in recent years and is generally being accepted as a clinical entity. There are still a few who hold that it is not a clinical entity but a radiographic sign caused by and associated with various intra-abdominal lesions. However, most competent observers in this field have come to consider it as a distinct clinical condition. Various descriptive terms have been applied to it, such as arteriomesenteric occlusion, congenital fixation of the duodenum, stenosis of the duodenum, megaduodenum, chronic duodenal ileus or stasis and chronic intermittent duodenal obstruction.

There are several causes of the condition. But in this discussion we shall confine ourselves to the two that are the most frequent and important. First, there is the group of cases due to peritoneal adhesions or bands, congenital or inflammatory, fixing the first and second parts of the duodenum. Secondly, there is the group of cases due to intermittent obstruction of the third part of the duodenum. This is caused by pressure of the mesenteric pedicle with its contained blood vessels or by the ligament of Treitz on the duodenum or by a very sharp occlusive angle at the duodenojejunal flexure. In spite of the growing literature on the subject, these conditions are not yet generally appreciated or recognized. Their importance is realized when it is understood that not a few of the vague and indefinite chronic disturbances of the gastro-intestinal tract are assignable to them.

The clinical part of this report is based on a study by one of us (H. F. S.), of forty-six cases of chronic intermittent duodenal obstruction. Only cases that have been thoroughly studied and followed for a sufficient length of time to reveal something of their subsequent clinical course have been included. The period of observation has varied from six months to eight years. While the group is not large, it seems adequate to serve as a basis for the discussion of our subject.

RESULTS OF OBSERVATIONS

Incidence.—The occurrence of chronic intermittent duodenal obstruction has been reported in patients as young as 3 years and as old as 68. Our youngest patient was 11 years of age and the oldest, 59. Most of the patients (thirty-four) were between the ages of 25 and 35. There were four times as many females (thirty-seven) as males (nine). In this series there were fourteen cases of obstruction at or near the duodenojejunal angle and thirty-two in which the obstruction was in the first half of the duodenum. This division is somewhat arbitrary, as there were at least eight instances in which partial obstruction seemed to be present in both parts of the duodenum.

Symptomatology.—The symptoms of this condition are extremely variable, vague and noncharacteristic especially in the milder forms. The most common symptom in this series was a feeling of epigastric fulness and flatulence, especially after meals. This was also Wilkie's [1] experience. Several of the patients had had digestive disturbances such as constipation, vomiting and "bilious attacks" from early childhood. Others did not show symptoms until early adult or middle life. In the latter group, trouble frequently followed some preceding debilitating illness, such as grip or a marked loss in weight or a period of being generally "below par." The explanation of this is not clear.

Pain.—Pain of some degree was present in eighteen cases (40 per cent). Usually it was in the epigastric region; at times it was more in the right epigastrium (in patients with adhesive bands about the first part of the duodenum). In those patients with obstruction at the duodenojejunal angle, it seemed to be more in the left epigastrium. It varied from mild discomfort or distress to sharp and, at times, severe pain. In some cases, it came immediately after eating; in some, from one to three hours after meals, as in peptic ulcer, and in others it was almost continuous. The feeling of fulness and flatulence was often present with the pain. Eructations of gas were present in most patients. Partial or complete relief was obtained by sodium bicarbonate, belching, an enema, or by assuming the knee-chest position. Several patients had learned the method of securing relief by the use of the knee-chest position. Usually the pain disappeared when the stomach was empty. The distress or pain experienced by these patients frequently followed excessive fatigue, nervous or emotional strain, coarse food or large meals.

Vomiting.—Nausea and vomiting were outstanding symptoms, occurring in nearly 50 per cent (twenty-two) of the cases. Many patients complained of troublesome nausea and persistent anorexia that seriously interfered with their gaining weight. Others suffered with periodic attacks of vomiting usually associated with varying degrees of headache. These attacks were usually described by the patients as "bilious headaches" and not a few stated that they began in early childhood. In a few patients the vomiting lasted from twenty-four to forty-eight hours, and the vomitus in these cases almost invariably contained bile. The headaches in some instances were of the typical migraine type, but in only a few cases was there a clear-cut history of the familial feature so common in migraine. The six-hour gastric retention discovered by roentgen examination in some patients undoubtedly played an important rôle in causing anorexia, nausea and vomiting. In many patients, it would seem, there are disturbances in intestinal peristalsis or the intestinal gradient as described by Alvarez.

Constipation, often quite obstinate, was present in most cases, though in a few (six) constipation alternated with diarrhea. About one half of the patients had lost varying amounts of weight. In some cases the symptoms were continuous; in others they occurred in attacks of varying duration with remissions of comparatively good health lasting a few weeks, months or even years.

[1] Wilkie, D. P. D.: Chronic Duodenal Ileus, Am. J. M. Sc. **173**: 643 (May) 1927.

Toxic Symptoms.—Many of the patients presented one or more so-called toxic symptoms. Conspicuous among these were headache, severe migraine, excessive fatigue, lassitude, mental depression, insomnia, nervousness, emotional instability and poor concentration. The mechanism producing these symptoms is far from clear, though various theories about toxic duodenal contents have been advanced. These nervous, functional or toxic symptoms frequently so completely dominate the clinical picture that the condition is considered to be a gastro-intestinal neurosis. As a consequence, and especially if no roentgen investigation is made by a competent observer who appreciates these conditions, the real diagnosis may be entirely overlooked. Such cases are then diagnosed as autointoxication, nervous indigestion or neurasthenia. There was no clear-cut difference between the symptoms of obstruction occurring in the first half of the duodenum and those present when the obstruction was at the duodenojejunal angle. In general, however, I received the impression that the pain or distress was more frequent on the left side; that it was apt to be more severe and that vomiting, when present, was more frequent and pronounced in the cases with duodenojejunal obstruction. Appreciable six-hour gastric retention, as shown by roentgen examination, was more frequent in the patients having obstruction in the first half of the duodenum. Consequently, as one would expect, a higher percentage of patients were operated on in this group.

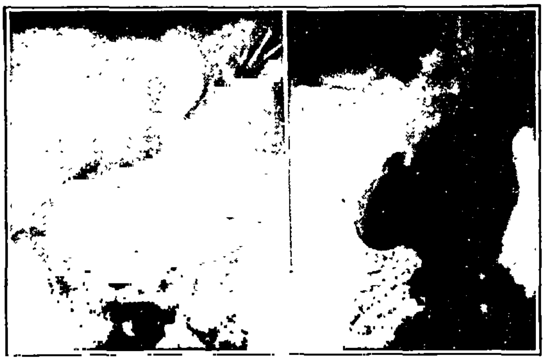

Fig. 1.—Small duodenum due to periduodenal bands.

Physical Examination.—This is important chiefly to rule out other intra-abdominal lesions. Most of the patients are of the asthenic type with the narrow costal angle and broad pelvis usually found in visceroptosis. All of the patients with obstruction at the duodenojejunal angle had this habitus. But seven patients with obstruction in the first half of the duodenum had a normal habitus. The majority of patients had low blood pressure, poor muscular tone, hyperactive reflexes and signs of vasomotor instability. More than half of the patients had diffuse epigastric tenderness; in some it was more on the right side, in others more on the left.

Laboratory Investigation.—Gastric analysis was carried out in thirty cases but showed nothing characteristic. Hypo-acidity, normal acidity and hyperacidity were present in nearly equal proportions. Blood was not found in the stools, though an excess of mucus was frequently present. Some of the patients had a mild secondary anemia, and in four it was marked. The basal metabolic rate was increased in two patients and appreciably low in three.

Roentgen Observations (H. M. I.).—The roentgen observations usually presented are characteristic in appearance but may at times be difficult to determine. In the first group, in which bands are present about the first and second parts of the duodenum, one finds that the duodenum may be markedly contracted in size in comparison to what one would expect to find from the size of the stomach (fig. 1); or it may be larger than the normal (fig. 2). Again, the duodenum may be deformed, presenting an appearance which is more or less analogous to that of ulcer, but the deformity is not constant as in ulcer and varies from time to time in various positions (fig. 3). The upper part of the descending limb may be definitely fixed and the part adjacent to the liver may have a flattened appearance. Normally there is a curve at the junction of the first and second parts of the duodenum, but when a certain type of band is present the curve is destroyed and the duodenum presents a horizontal line rather than a curve (figs. 4 and 5). A commonly observed phenomenon is a fixation of the dependent limb of the duodenum to the liver at a certain point, producing a definite angulation (fig. 6). These various phenomena may cause sufficient atresia of the duodenum to produce eventually a slowly emptying stomach. In an obstruction at the angle of Treitz the appearance is quite characteristic (figs. 7 and 8). The angle is usually shifted to the right of its normal position, so that it lies either over the body of the third lumbar vertebra or even to the right of it. The dependent duodenum is usually enlarged especially in its transverse diameter, and the valvulae conniventes are frequently absent. The duodenum is not able to empty itself completely and there is more or less reverse peristalsis with considerable writhing and twisting. These phenomena are frequently observed in a normal duodenum and to be of any diagnostic significance the phenomena must be observed after digestion is well established. The motility of the stomach is frequently seriously interfered with as it is not uncommon to see retention.

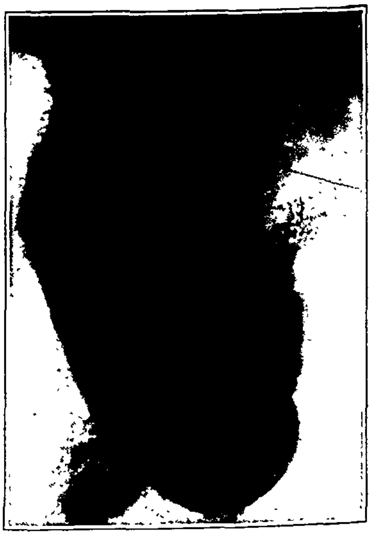

Fig. 2.—Elongation of duodenum due to bands at its extreme apex.

Associated Lesions.—Duodenal ulcer was present in three cases of this series, and an operation was performed in two. Four patients had cholecystitis (two with gallstones). All were operated on. More than half of the patients who came to operation for intermittent duodenal obstruction had had their appendixes removed when we first saw them. In none of these had the symptoms improved following the removal of the appendix. Niles[2] has already pointed out the frequency of the removal of the appendix in patients with duodenal obstruction.

REPORT OF CASES

CASE 1.—*Intermittent obstruction at the duodenojejunal angle (angle of Treitz).* A single woman, aged 50, had complained of indigestion, nervousness and exhaustion for seventeen years. For three years she had suffered with distress in the left side of the epigastrium, flatulence and belching from one to three hours after meals. During her worst attacks she secured some relief following an enema or by assuming the knee-chest position. She was usually severely constipated and had periods of headache, exhaustion and mental depression. There was slight tenderness in the left side of the epigastrium but the physical examination was otherwise essentially negative. A cholecystogram showed normal conditions. But the gastro-intestinal roentgen examination showed signs of obstruction at the duodenojejunal angle (angle of Treitz) characterized by inability of the duodenum to empty completely, reverse peristalsis, and writhing and twisting of the duodenum. After following a regimen of special diet, rest after meals and postural treatment, and wearing an abdominal belt for a suitable time, the patient was greatly improved and was able to resume her occupation as a nurse.

CASE 2.—*Marked fixation of the first and second parts of the duodenum.* A man, aged 59, had suffered from "bilious attacks" consisting of anorexia, lassitude, headache, depression, nausea and vomiting, since he was 10 years of age. The attacks lasted one or two days, occurring every few months at first, but during recent years they came every two or three weeks. Usually they seemed to be induced by overeating or excessive fatigue and were relieved by fasting or small meals and rest. There was no abdominal pain or distress. When 40 years old, the patient had a "nervous breakdown" lasting five years. He was markedly underweight, the blood pressure was low, and he had a pronounced visceroptotic habitus. Roentgen examination showed a long vertical stomach, which contained about 30 per cent of the barium at the end of six hours. This was due to an unusually sharp fixation and angulation of the apex of the duodenum. Because of the marked changes on roentgen examination and the failure of previous medical treatment, surgical intervention was advised. At operation, a pronounced duodenohepatic band was divided, which released the duodenum so that it assumed its normal shape and position. Striking improvement followed the operation. The "bilious attacks" stopped; there has been no vomiting and the patient gained 35 pounds (16 Kg.) in six months, his weight increasing from 120 pounds (54.4 Kg.) to 155 pounds (70.3 Kg.). He has been well for nearly two years.

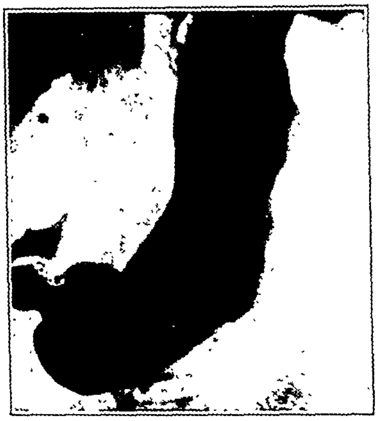

Fig. 3.—Irregularity in outline of greater curvature surface of duodenum due to pressure from without.

CASE 3.—A girl, aged 11, had complained for one year of attacks of sick headaches accompanied by nausea, vomiting and epigastric pain. During the previous two months the attacks had become more frequent and severe, and she had lost several pounds. Physical examination showed only that she was under weight and that she had a moderate enteroptotic habitus and some epigastric tenderness. Roentgen examination showed intermittent obstruction at the angle of Treitz characterized by slow emptying of the stomach, reverse peristalsis, writhing and twisting, and stasis in the most dependent part of the duodenum. Under medical treatment the patient slowly improved, and she had had only two slight attacks of headache and vomiting during the past two years.

CASE 4.—A married woman, aged 46, complained of "bilious attacks" consisting of severe headache, nausea and vomiting with marked prostration for two or three days. She had suffered from these symptoms for twenty-five years but during the past few years the attacks had become more frequent, occurring every two or three weeks. Indiscretion in eating, overfatigue, or an emotional upset often precipitated an attack. Rest in bed and a fluid diet gave quicker relief than anything else. Three years previously she had had a severe attack of abdominal pain in the left upper quadrant. Since then she had had several milder attacks and had been troubled with flatulence and gas after eating. Physical examination showed no important abnormalities. The roentgen examination showed a stomach that was not quite empty in six hours, with the apex of the duodenum fixed and angulated. A cholecystogram disclosed a slowly emptying gallbladder containing a single large gallstone. The gallbladder and its contained stone were removed without complications. The attacks of abdominal pain on the left side ceased, but within a short time after the cholecystectomy the "bilious attacks" with headache, nausea and vomiting returned. Medical measures brought little relief. A second roentgen examination, made nearly a year after the first, showed the same condition of duodenal fixation as was found at the first examination. Following a second operation with release of the constricting bands about the duodenum, the patient was almost entirely relieved of the attacks and has been quite well for many months. It is possible that this was purely a case of cholecystitis and adhesions involving the first part of the duodenum. It is interesting, however, that the long standing digestive disturbances called bilious attacks were not controlled until the operation devised for cases of fixation of the duodenum was performed.

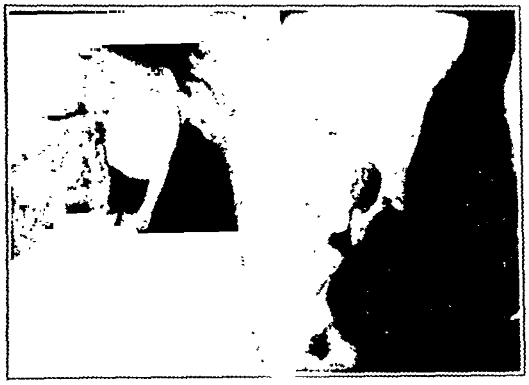

Fig. 4.—Angulation and high fixation of the duodenum.

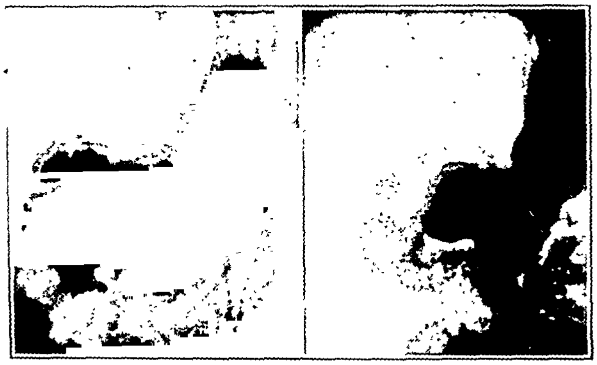

Fig. 5.—Redundance of upper part of descending limb of duodenum.

TREATMENT

The treatment for this condition constitutes a rather difficult problem. Much of the difficulty concerns the decision as to which patients should have the benefit of surgical measures. At present, we think that a conservative attitude regarding operation is the best one. And yet a certain number of cases undoubtedly require surgical intervention for relief or cure. In this series of forty-six patients, eight have been operated on, five with excellent results, one with moderate benefit and two with no improvement. And as the condition, even without treatment, is not rapidly progressive, we think that with few exceptions medical measures should be given a thorough trial before resorting to operation. In this series, thirty-eight patients were treated medically. A survey of the literature on the subject shows that practically all observers are agreed that the vast majority of these patients do not require operation and that they respond very satisfactorily to medical treatment.

Medical measures are largely concerned with treating the visceroptosis, constipation and nervous symptoms. Diet is important. As most of the patients are underweight, the diet should be of high caloric value. In addition, all foods should be thoroughly cooked and the vegetables puréed, giving a bland, low residue, so-called smooth diet. Frequent small meals should be given, at least during the earlier part of the treatment. There should be enough fruit and vegetables to help overcome constipation. Often these patients have a spastic or irritable colon which needs appropriate care. With some patients the best plan is rest in bed with forced feeding until a substantial gain in weight has been made. A course of postural treatment is most helpful. Wilkie[1] has already emphasized this. The treatment is carried out by elevating the foot of the bed, elevating the hips, or having the patient lie on the stomach or right side after meals, or assume the knee-chest position for short periods each day. Some patients will obtain marked relief during an acute attack by the last procedure, as was the case with three of the patients. In many instances a properly fitted corset or abdominal belt is needed to overcome the traction of the mesenteric pedicle at the angle of Treitz and of the stomach on the first half of the duodenum. A course of abdominal exercise and massage will help muscle tone considerably. Phenobarbital or bromides are useful for the nervous symptoms resulting from spasm of the pylorus, duodenum and colon. Constipation requires laxative nonbulky food, liquid petrolatum and agar, but laxatives should be avoided. The patients should be kept under prolonged observation to get the best results from medical treatment. Continued perseverance is required of both patient and physician.

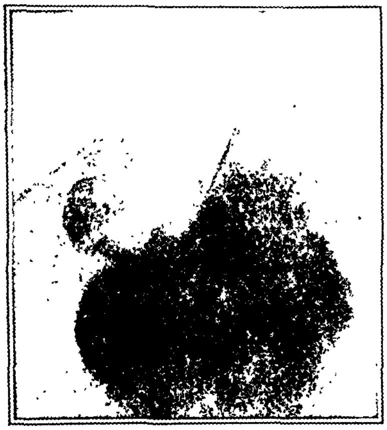

Fig. 6.—Narrowing of descending limb of duodenum caused by bands.

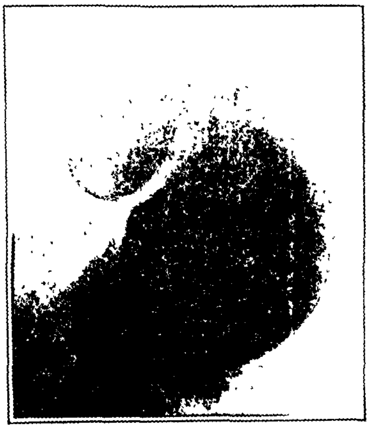

Fig. 7.—Dilatation of duodenum resulting from obstruction at the angle of Treitz.

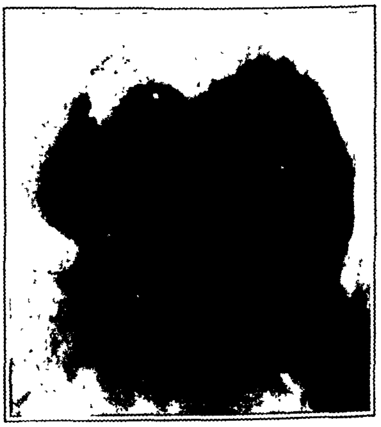

Fig. 8.—Another example of dilatation of the duodenum resulting from obstruction at the angle of Treitz.

If satisfactory results are not obtained by conservative treatment, surgical intervention should be considered. The following considerations should help to decide the question of operation: the result of suitable medical treatment carried out for a sufficient time; the amount of obstruction at the duodenojejunal angle with its resulting stasis in the dependent loop of the duodenum; the extent of the duodenal fixation, especially if accompanied by a six-hour gastric retention, and the severity of the symptoms especially of pain and vomiting. Young patients with short histories and severe pain and vomiting seem to get the best results from operation. Division of constricting bands seems to be the operation of choice for cases with fixation of the first half of the duodenum, while duodenojejunostomy is best suited to the cases of obstruction at the duodenojejunal angle. The more radical operations with their greatly increased risk are not justifiable. The postoperative care of these patients is extremely important. The best results are obtained when a suitable diet, massage, postural treatment and an abdominal belt are used during convalescence. In the most marked cases with a short history, marked roentgen changes and considerable epigastric pain, the results of operation are quite striking. This was the case in four of the eight patients operated on in this series.

SUMMARY

1. Chronic intermittent duodenal obstruction or ileus is generally accepted as a clinical entity.

2. The two most frequent and important causes of the condition are, first, peritoneal adhesions or bands fixing the first and second parts of the duodenum, and, second, pressure of the mesenteric pedicle, or a sharp occlusive angle at the duodenojejunal flexure causing obstruction of the third part of the duodenum.

3. The present study includes forty-six cases of this condition, eight of which came to operation.

4. The symptoms are extremely variable and noncharacteristic but should suggest the possible presence of the real trouble in many instances and lead to careful roentgen study as a consequence.

5. Accurate diagnosis depends largely on a careful and skilful roentgen study. The characteristic roentgen observations found in the various types are described.

6. The great majority of these cases respond satisfactorily to medical treatment, but there is a small group with pronounced symptoms and marked roentgen observations which does best with conservative surgical measures.

THE TREATMENT OF FRACTURES BY MEANS OF SKELETAL DEVICES

WITH FIXATION IN PLASTER-OF-PARIS CASTS *

H. WINNETT ORR, M.D.
LINCOLN, NEB.

It may be said that the objective of fracture treatment was formerly to secure the patient's recovery with the injured part or parts in good contour and with the fracture fragments in as good position as appeared to be possible. At present, much more attention is being paid to restoration of function. And with the more general use of the x-rays during and after fracture treatment, it is becoming apparent that restoration of correct anatomic position of the injured parts goes hand in hand with the return of satisfactory function. Not only the medical profession but also the public is becoming aware that accuracy of reposition of fragments in fractures is essential to obtaining uniformly good functional results.

It is well known that, whatever occasional statistics may seem to indicate, satisfactory results as to anatomic reposition and physiologic efficiency are not being obtained regularly. The faults of fracture treatment lie obviously at two points: (1) the failure to obtain good primary position, and (2) the inability to control the fracture or the patient after (if) the fracture has been properly reduced. Some of the difficulties in these respects arise out of the clinical teaching of textbooks and medical schools, but this simply reflects a difficulty further back; the source of failure lies in the perplexity of the profession as a whole in the face of a confusion of what are thought to be principles of treatment. There are so many "solutions," new and old, for the familiar problems that one is at a loss, sometimes, to discover which are really in accord with the manifest indications for treatment.

Witness, as examples of these confusing tendencies, the precepts of the schools and the treatises: 1. Plaster of paris should never be used in treating fractures. 2. If plaster of paris is used as a circular cast, the cast must always be split. 3. The Thomas splint is always indicated for the hospital treatment of compound fractures. 4. The Thomas splint must never be used except as an emergency splint. 5. The use of ice tongs, pins and other skeletal devices is dangerous because likely to produce infection or injury to neighboring joints. 6. It is of primary importance to establish early motion, especially in compound fractures. The list might be extended. The task is rather to suggest which of these divers methods best conform to fundamental surgical principles and which may be united into a more effective procedure for treating fractures. For it is probably not a confusion of fundamentals that is perplexing but rather the various technics thought to be useful in applying them.

BACKGROUND

The history of fracture treatment in this country, as elsewhere, is the story of dozens of methods, a myriad of braces, splints and other apparatus, and a variety of "principles" to justify each procedure. Out of the chaos one finds emerging, in the early years of the last century and, of course, before the antiseptic era, these precepts: (1) extension and counterextension in direct line of the affected member; (2) splinting to hold fragments in their proper places; (3) immobilization, as efficient as possible, giving rest until healing is well under way and (4) in compound fractures, treatment of wounds by cleansing, application of cold water and use of various lotions.[1]

After Lister's time, various changes were made to permit the antiseptic care of wounds. Lister himself endeavored to exclude infection from wounds by his use of antiseptic dressings; later surgeons, departing from Lister's teaching, carried into the wounds themselves the war against infection. In 1922, the older methods of fracture treatment, embracing those already mentioned and others evolved in the latter part of the nineteenth century, were summarized by Boorstein and Landsman as follows:[2]

1. Reduction of the fracture after the swelling has subsided.
2. Reduction of the fracture by direct pull.
3. Immobilization as far as possible of the joints above and below the break.
4. Application of a straight splint though the limbs are usually round. [By no means universally the case, and probably not from principle. Cf. Dr. Philip Syng Physick's curved splint for morbus coxarius.[3]]
5. Securing of immobilization of bone and joint by bandages left in place until firm union has occurred.
6. Allowing the soft parts (skin, nerves, vessels and muscles) to take care of themselves.
7. Contour or union in good position the main aim.
8. Prolonged confinement in bed.
9. Correction later on of deformity if it occurred during treatment. It is often considered inevitable.
10. Roentgen ray used only once or twice during the entire time.

This is the old decalogue! Today much of it has been put aside, and we gather from a similar summary, by Boorstein and Landsman, of modern methods and from other sources that the present "commandments" are these:[4]

1. "Splint 'em where they lie!"
2. Immediate reduction.
3. Selection of apparatus which will maintain reduction, but,
4. Provision for its early removal (or disturbance) to permit inspection, dressings, and massage or motion.
5. Plaster of paris permitted only when completely divided in at least one line. Circular plaster-of-paris splints should always be split.
6. Traction splints usually indicated. If plaster is used, it must be split.
7. Skeletal traction, when used, is in conjunction with a suspension splint.
8. For compound fractures, débridement is to be followed by primary or partial closure, or by some other form of active antiseptic treatment.

With all these conflicting procedures, remote, recent and contemporary, the profession is confronted. Little wonder that the more fundamental principles have been

---

lost sight of and that confusion has resulted. Or, if it is said that the fundamentals have not been lost sight of, then it must be admitted that the profession is not using the best methods at its disposal for the most effective application of them.

PRINCIPLES

Now the principles of all fracture work should be apparent: (1) immediate restoration of correct length and position; (2) maintenance of that length and position; (3) complete rest to preclude muscle spasm and other complications and to facilitate healing; and, in compound fractures (in addition to the foregoing), (4) primary asepsis or antisepsis to reduce infection; (5) adequate drainage; and (6) protection against infection or reinfection. Immobilization, in connection with the third of these principles, must be so effective that all movement is prevented and so that pain and muscle spasm are relieved. Without elaborating further, the fact may be pointed out that, whereas some of the older methods sought to realize these principles, many of the modern ones lose sight of them; hence the results are poor.

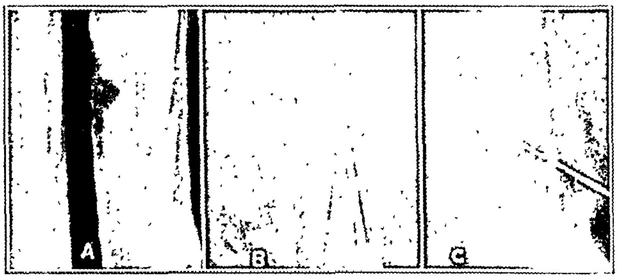

Fig. 1.—*A*, fracture of tibia and fibula in a child, aged 10 years; pin traction through calcaneum and direct fixation of fragments; *B* and *C*, lengthening and fixation done after seven weeks of shortening during which firm union had occurred in malposition. Full length was secured on the operating table; the pins through the calcaneum and in the fragments were embedded and left in the cast.

PROPOSALS

A somewhat new attempt to fulfil some of these basic requirements in the treatment of fractures came soon after the war with the so-called fixed traction of Sinclair, Pearson and others. Using ice tongs and pins for skeletal traction in combination with Thomas splints, they got much better results than were usual and convinced me, at least, of the value of such devices. Even these, however, were not without complications in the way of slipping points (of ice tongs), loss of position, and the like; and the need for an even more truly "fixed traction" was apparent.

This was recognized by several of us. T. Turner Thomas[5] sought for greater security in fractures of the leg, using an iron plate having a sharp spike at one end, which plate he placed against the plantar surface of the foot and then included in a foot-cast, which was well padded to permit its use in securing extension. He then placed a board splint along the back of the entire extremity and included leg and splint in a second cast extending above the knee. These casts having set, he reduced the fracture by a pull on the foot-cast, and maintained reduction by driving the spiked plate perpendicularly into the wooden splint where it extended beyond the heel, and then included the entire extremity in a third cast.

My own effort to achieve fixed traction was inspired rather by the technic of Sinclair and the others in the use of the Thomas splint. But to avoid the complications which they occasionally had and, at the same time, to conform more exactly to principles of immobilization, securing full length, maintaining correct position, and avoiding pain and muscle spasm, I modified this technic. Securing traction on the operating table at the time of primary reduction, I fixed the entire traction apparatus, moleskin adhesive plaster, ice tongs, pins or whatever form they took, in a plaster-of-paris cast. I[6] advocated this practice in simple fractures shortly after the World War:

> 1. The usual splint applied to fractures does not immobilize at all. This applies even to the usual plaster-of-paris cast.
>
> 2. A considerable number of splints applied to fractures that are followed by joint stiffness have been put on too tight. This fault is as serious as having splints too loose. Even splints that are bandaged too tightly may not immobilize. . . .
>
> 3. Uniformity in results after fractures was obtained in France during the military activity more nearly by a standard method of splinting than has ever been accomplished in civilian practice.
>
> 4. In fractures of the femur, the general adoption of the Thomas splint, which gives traction and immobilization (if properly applied) either from the skin or from the bones themselves (ice tongs, pins, etc.) without constriction, will contribute greatly, not only to better results in the alinement of the fragments, but also to a very great reduction in the amount of joint stiffness and disability after such injuries.
>
> 5. In other fractures, especially of the forearm, leg and spine, the more general use of plaster of paris, applied so as to give real immobilization, will reduce the amount of pathologic change, secure more rapid healing of the injured part, and give more and better function in adjacent joints than can be obtained in any other way.

and two years later for compound fractures as well.[7] I soon found that this technic gave much better results, especially since I have applied to the treatment of compound fractures, as well as to osteomyelitis, the petrolatum packing technic of drainage and rest.[8]

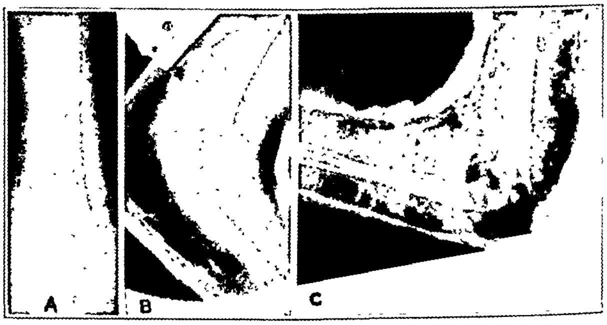

Fig. 2.—Old fracture at lower end of humerus left in malposition brought into better position (*C*) by traction pins through the olecranon and through the middle third of the humerus. After strong traction on these two pins and flexion at the elbow, length and position were maintained by a cast including entire arm and pins.

In dealing with simple fractures, my procedure is this: The patient is anesthesized on the fracture table as soon as possible after the fracture. The regular traction devices, which are a part of the table, are used in those fractures for which they are suitable, but for others special devices are put on or improvised so that fixed traction may be made on the injured part. In those cases in which, with suitable traction, the ends of the fracture fragments may be made to lock together in correct line and apposition, no additional special device is necessary for controlling the fragments. In many simple fractures, however, especially of the forearm and the leg in the lower third, even after good traction, position cannot be maintained. In such cases I do not hesitate to use ice tongs or pins, so that with traction complete and the fragments in correct position, these ice tongs or pins may be incorporated into the plaster cast as it is applied. With the hardening of the cast, then, the fragments are locked, as it were, in a position of full length, and cannot slip back or rotate. In the case of compound fractures, the foregoing procedure is altered as follows: The fractured extremity is immobilized on the traction table, as soon as the anesthetic has been administered, in good position and with full length. This is done with the smallest possible number of movements. The area of the compound fracture is opened widely and provision made for drainage and for packing the entire space wide open with petrolatum gauze. Débridement and mechanical, or even chemical, antiseptic cleansing are resorted to as a part of this first "clean-up" operation.

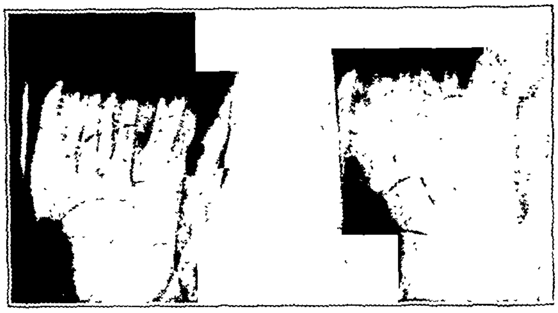

Fig. 3.—Position obtained by use of pin traction through toes. A heavy metal loop extending beyond the toes is embedded in the cast; pins are put through the second phalanges (in this case) of the third and fourth toes only. Twist traction (Spanish windlass) from the pins to the metal loop draws the toes out to perfect length and position for the metatarsals.

As in the case of simple fractures, the fragments are brought into as good position as possible and then, if it appears that it will be difficult to control the fragments, ice tongs or pins are inserted on one or both sides of the fracture area so that they will prevent rotation and maintain the length and position of the fragments when they are included in the cast. The wound then having been packed open with petrolatum gauze and the pins or ice tongs inserted as necessary, a dry sterile dressing is placed over the petrolatum packing and an extensive plaster-of-paris cast is put on. Position and control are thus such that the original deformity is corrected at once and cannot recur. Muscle spasm is prevented; pain is minimized; and the wound, while free to drain, is protected against reinfection.

Finally, there is no provision made for postoperative dressings.[9] If it happens that bleeding or other discharge becomes profuse, so that all the dressings and the cast are saturated, a change of the outside dressings may be done through a window in the cast and under strictly aseptic conditions. The wound and wound surface, however, should not be disturbed and, of course, nothing should be done to alter the position of the limb or fracture fragments.

RESULTS

To discuss argumentatively all the perhaps controversial points involved in this procedure would not be practicable. Most of them have been discussed before.[10] It will be enough for my present purpose to tabulate and to describe the results of treatment according to this technic.

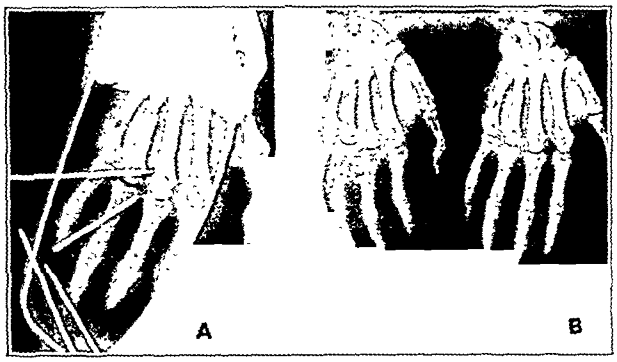

Fig. 4.—*A*, details of pin traction and fixation for fracture of fourth and fifth metacarpals. The metal loop embedded in the cast extends beyond the tips of the fingers, furnishing an "anchor point" for traction pins through the phalanges of the fourth and fifth fingers. Fracture fragments had been in extreme malposition. End-result (*B*); pin marks show no sign of infection.

To review some of the suggestions made at the beginning of this paper, it has been found important to give first thought to the functional result which the physician hopes to achieve. Anatomic reposition, recovery with all parts in as nearly perfect anatomic position as possible, contributes more than anything else to good functional results. It has been my experience that this is true even in those severe compound fractures with considerable loss of substance in which great disability is ordinarily expected. Excellent results have been obtained by this simpler method as a result of its saving of wear and tear on the patient, its prevention of muscle spasm and pain, the minimum of damage to soft parts and the reduction of infection, all of which contribute to an early recovery with the parts in good position.

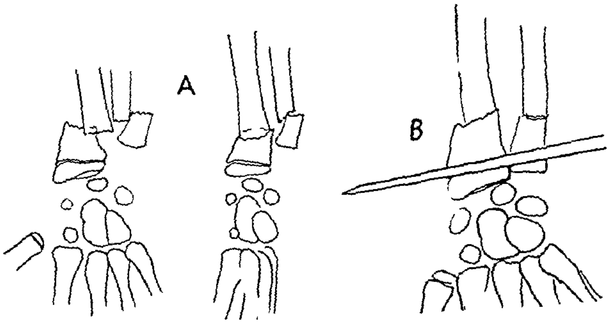

Fig. 5.—A difficult fracture of the forearm with the position obtained at once (*B*) without open operation by use of traction on one pin through the olecranon and a second pin, as shown, through the distal fragments of the radius and ulna. (The case was of a child, aged 10 years.) The length and position secured by traction on the operating table were maintained permanently by a cast which included the entire arm and the pins. Cast and pins were removed after four weeks.

The accompanying tables and illustrations will explain something of my technic and results. In referring to the tables, it is to be borne in mind that a patient pronounced healed or cured has practically a full return of function. Compound fractures were chosen for these tables since, as the general principles are the same as for other fractures, their greater technical difficulty offers a severer test for the method which I advocate. The high percentage of good results may be attributed to the various advantages of the simpler procedure, as shown in the tables.

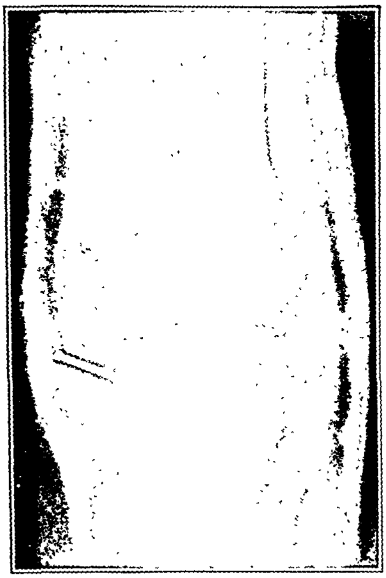

Fig. 6.—An old fracture of the internal condyle of the tibia with bow leg deformity and considerable disability of a year's standing in a patient, aged 45. The fragment was depressed so that the joint surface of the tibia was much lower on the inner side of the knee. By means of an oblique osteotomy, the depressed fragment was raised and fastened in place by a nail. No opening was made into the joint. The entire extremity (with the pin) was kept in the cast for six weeks; almost complete correction and relief were obtained.

The illustrations show various uses of skeletal traction obtained by using pins embedded in the plaster-of-paris cast. We have also employed pins through the heel and through the tibia in two cases of severe compound fracture of the ankle with additional direct fixation of fragments in the wound. With the wound packed open with petrolatum gauze and then covered over with dry sterile gauze (without the use of drainage tubes or stitches), a closed cast including the ends of all the pins was applied. The fragments were controlled, and there was niether muscle spasm nor inflammatory complication. Pins in the wound area were removed in two weeks without opening the cast; those in the tibia and heel were taken out after six weeks. Excellent results were obtained in both cases.

It is clear, then, that while there should be no quarrel with some of the modern precepts of fracture treatment, such as the necessity for emergency splinting and for immediate reduction, one should, on the other hand, look back to some of the older teachings which emphasized rest, immobilization, and dependence on natural agents in healing. Today's methods differ from the older ones, of course, in that they can achieve more perfectly, by the use of modern apparatus, the objectives which the latter perhaps seldom realized. At the same time, however, such modern apparatus and practices as are involved in any hand to hand combat with infection in the wound (irrigation tubes, drainage tubes, antiseptic applications in daily dressings, for example) are discarded, and the benefits of rest and immobilization are put ahead of whatever leads to disturbance or movement of a healing fracture.

In addition to the results previously indicated must be added these points which, especially in compound fractures, also recommend the procedure that has been described: (1) The fracture is better managed; (2) the patient is better managed; (3) the patient requires less constant attention from surgeon, assistants or nurses; (4) the period of hospital care is shortened; (5) the cost to the patient is, because of several of these considerations, lessened; (6) there is relief from the pain of daily dressings, particularly important in the care of children; (7) the possibility of secondary infection is minimal; (8) there is adequate drainage in a wound which is, from the point of view of drainage, open but, from that of infection, closed.

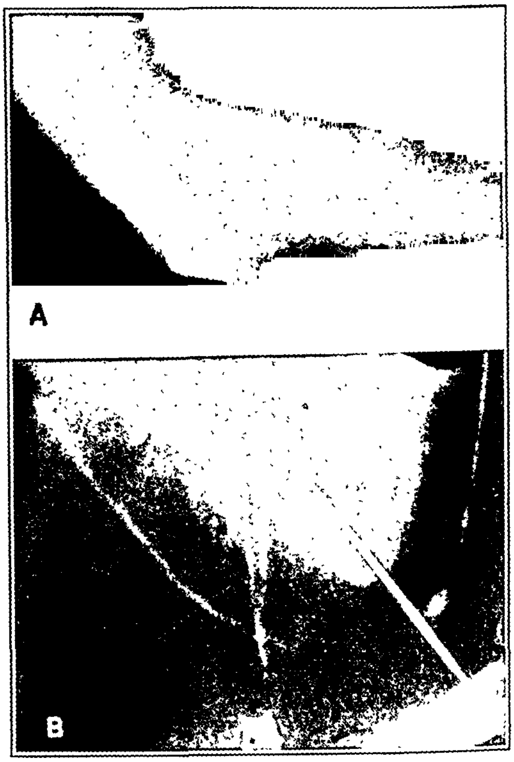

Fig. 7.—Direct pin fixation of a recent fracture of the olecranon in a patient, aged 60. *A*, fixation in this manner may be accomplished easier without open operation by first transfixing the small fragment, then carrying the fragment on the end of the pin into correct position, and then forcing the pin through into the shaft of the bone. *B*, the arm can then be flexed at the elbow, which is very desirable, and the arm and pin immobilized in a cast.

SUMMARY

1. The modern demand in the treatment of fractures, both from the profession and from the public, is for correct anatomic replacement of injured parts and recovery with a maximum of function.

2. The higher development of the roentgen ray and specialization in treatment renders unavoidable a more critical attitude toward the treatment and end-results of fractures.

3. The treatment of fractures by weight and pulley or elastic traction and by less than highly efficient methods of fixed traction in splints has given no more than a rather low percentage of first class results.

4. Technic must therefore be improved, both in the primary reduction and postoperative treatment of fractures, and in the control of the fracture and the patient during the period of healing.

5. The use of skeletal traction devices—ice tongs, pins and even direct fixation of fragments at the point of fracture—and the incorporation of these fixation devices in a plaster-of-paris cast has given better control of the fracture than any other splint.

6. The former objection to plaster of paris, that it becomes soiled because of discharge from compound fractures and that it must be removed for postoperative dressings, no longer holds. The technic that I use in osteomyelitis and have also applied to compound fractures permits the application of a primary dressing which, in most cases, is left undisturbed throughout the entire period of healing.

7. The results that I have had, following these principles and methods of treatment, are better than those reported for other methods.

1307 N Street.

ABSTRACT OF DISCUSSION

DR. HARVEY C. MASLAND, Philadelphia: Operative skeletal traction is an acknowledgment of the fact that the old time-worn mechanics is futile for good reductions of bad fracture deformities. I wish to call attention to a skeletal traction method absolutely nonoperative. It seems to be accepted with a fatalistic conviction that there can be no improvement along strictly nonoperative lines. After an experience of more than eleven years with a distinctly new type of splint, I assert with all emphasis that nothing is farther from the truth. These splints use unpadded plaster casts and, where needed, adjustably fitted padded rings, with connecting arms, slidable over one another to give the necessary distention. The casts and rings brace against bone structures adjacent to the fractured bone. Nonoperative skeletal traction and countertraction are obtained in the normal alinement of the bone. The fractured bone is not covered. If the fracture is compounded, it can be dressed without disturbing the splint. Better than with any extension table, as now used, extension with greater safety to the soft tissues is secured. In intracapsular fractures of the femur these splints will give reductions as good as or better than with any other method. The knee joint and the hip joint are movable at all times. The fracture is stabilized. The patients can be propped up in bed to any position of comfort. They do not die from the punishment of the treatment. Results in fractures of other bones are even more gratifying. With regard to fractures of both bones of the forearm and of the shaft of the humerus as shown here this morning, I expect to obtain apposition of the fragments as a matter of routine. T-fractures of the head of the humerus with dislocation of the head are a separate proposition. I would make a plea for a higher grade of mechanics than has been in use for so many ages. A better type of nonoperative skeletal traction is safer for surgeons generally.

DR. C. W. DURHAM, Jackson Springs, N. C.: Do you use something to make a drill hole through those fractures or do you just drive the pin in?

DR. F. J. GAENSLEN, Milwaukee: I am in accord with Dr. Orr when he recommends skeletal traction and incorporation of the traction device in the plaster cast. The method finds application in a great many locations. Böhler has called attention to the fact that in fractures of both bones of the forearm great care must be used to have the proper degree of traction on the lower fragments so that when the pin is driven through the lower fragments the styloid process of the radius and ulna will be on the proper level. He also emphasizes the need of exerting moderate pressure to bring the lower end of the radius and ulna close together to avoid relaxation of the lower radioulnar ligament. He has an assistant making powerful traction on the hand, a counterpull being provided by a broad belt brought around the upper arm and fastened to a hook in the wall. Instead of the heavier steel pin we have used the Kirschner wire apparatus, with the greatest satisfaction. The wires are very small in caliber, make small wounds, and do not cut through either bone or soft parts. The Kirschner apparatus should make a welcome addition to the armamentarium of every man doing fracture work.

DR. H. WINNETT ORR, Lincoln, Neb.: I was going to make the point that Dr. Gaenslen mentioned. I used to hammer the pins in. Now I use a drill pin, which I find more satisfactory, a soft steel pin which will not break. One can put it in with an ordinary drill and with the point the same caliber as the shaft. In order to keep the records of the section straight on the matter of splinting with such provision for frequent dressing as the previous speaker mentioned, I want to say that it is the opinion of many physicians that it is never necessary to splint with provision for frequent dressings in compound fractures.

TULAREMIA

REPORT OF A CASE, WITH POSTMORTEM OBSERVATIONS AND A NOTE ON THE STAINING OF BACTERIUM TULARENSE IN TISSUE SECTION *

MARGARET FOULGER, M.D.
ALFRED M. GLAZER, M.D.
AND
LEE FOSHAY, M.D.
CINCINNATI

In a review of the literature on tularemia we have been able to find but eight cases in which the autopsy observations are reported. The first was put on record by Verbrycke[1] in 1924. His patient died eighteen days after the onset of the illness, and the lesions of tularemia were found in the lungs, spleen and lymph nodes. The next case was reported by Kolle and Wassermann.[2] This patient died twenty-six days after the onset of the illness, and the lesions were limited to the spleen. In 1927 Francis and Callender[3] described the case of a patient who died approximately five months after a presumptive exposure, and lesions were found in the lungs, liver, spleen and lymph nodes. In 1928 five more cases were reported. Bardon and Berdez[4] reported one in which the patient died sixteen days after the onset of the illness, and lesions were found in the liver, spleen and lungs. Goodpasture and House[5] made record of a patient who died eighteen

days after exposure, and lesions were found in the liver, spleen and lymph nodes. They also described the histologic picture of the primary lesion on the finger. W. M. Simpson[6] reported a case in which the patient lived but four days after the onset of the illness. At autopsy, lesions were found in the spleen, liver and lymph nodes. Palmer and Hansmann[7] placed on record a case in which the patient died eight days after the onset of the illness, and lesions were found in the lungs, spleen and lymph nodes, while a similar distribution of lesions was found in a case reported by Bunker and Smith,[8] their patient also dying eight days after the first appearance of the disease.

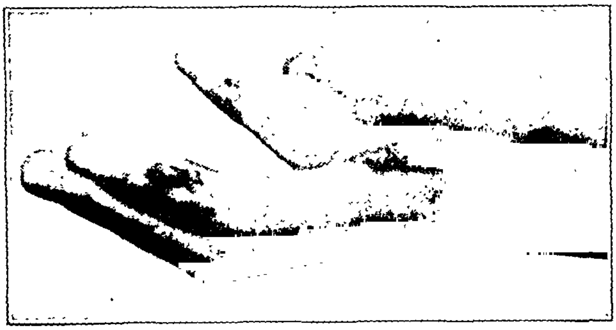

Fig. 1.—Multiple tularemic ulcers of fingers of left hand.

Because of certain unusual clinical features and the finding, for the first time, of lesions in organs other than the lungs, liver, spleen and lymph nodes, we present the following case. Furthermore, we believe it to be the first time that Bacterium tularense has been demonstrated in sections of human tissues:

History.—B. F., a white woman, aged 37, married, a housewife, was admitted to the Cincinnati General Hospital, Oct. 11, 1930, complaining of chills and fever and a sore finger on the left hand. The illness commenced rather suddenly, October 1, with severe chills and fever, general aching of the bones and vomiting. Twenty-fours hours after the beginning of the chill the patient felt a dull, aching pain in the entire left arm, particularly in the axillary region. Soon she noticed a small papulopustular lesion of the left index finger. On the following day there was enlargement and tenderness of two or three of the left axillary lymph nodes. The lesion on the finger was lanced by the family physician, and the enlargement of the axillary lymph nodes gradually subsided. Three days after the appearance of the lesion on the index finger the patient noticed a similar lesion on the small finger of the same hand. This was followed by enlargement of the left epitrochlear lymph node. The fever continued, and she had repeated chills, sometimes two in a day. She came to the hospital ten days after the onset of the illness.

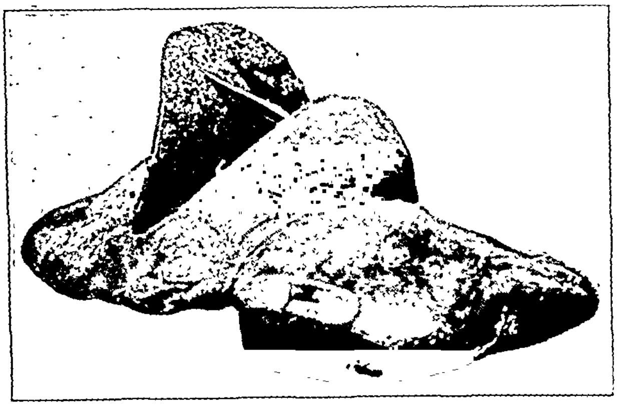

Fig. 2.—Liver with tularemic abscesses.

September 27, four days before the onset of the present illness, the patient was on a hunting trip with her husband and family in the south of Kentucky. Two or three rabbits were shot and dressed by the patient and her brother-in-law. So far as the patient knew, she had no abrasions of her hand at the time, nor did she cut her hand while dressing the animals. But the brother-in-law, who had a hang-nail, developed a papulopustular lesion of his finger and had mild chills and fever for a few days. These symptoms had ceased before the patient's admission to hospital.

The past history and the family history of the patient were irrelevant, except for the fact that a cousin died the preceding year of "rabbit fever," after an illness lasting seven days.

Examination.—The patient was well developed and well nourished, and apparently was acutely ill. The temperature was 103.6, the pulse 104, and respirations 26. The blood pressure was 110 systolic and 64 diastolic. The face was flushed. A small papulopustular lesion was present on the right side of the chest, near the costal margin, and another on the inner aspect of the right thigh. An ulcer, 1 cm. in diameter, with ragged edges, was seen on the index finger of the left hand, and a small pustule, 0.5 cm. in diameter on the little finger. One epitrochlear and one axillary lymph node were both enlarged to the size of a small marble and were firm and moderately tender. There was no other lymphadenopathy. There was no redness about the enlarged lymph nodes nor were there red streaks on the arm.

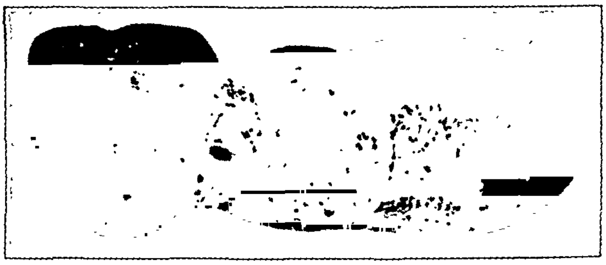

Fig. 3.—Spleen with tularemic abscesses.

Examination of the chest showed a slightly impaired percussion note over the right base, with numerous fine crepitant râles over both bases and in the axillary regions. The remainder of the physical examination gave essentially negative results.

Before the patient entered the hospital another pustule developed on the middle finger of the left hand. The temperature fluctuated between 102 and 105 F. No chills occurred after admission. One week after admission there was rather marked respiratory distress, resembling that seen in pneumonia but without cough or expectoration. Physical examination of the chest showed numerous râles in the lower lobes both anteriorly and posteriorly. At the same time the abdomen became distended and a rather marked diarrhea developed which did not respond to treatment. The respiratory distress and diarrhea persisted, and the patient became irrational and finally comatose twenty-four hours before death. October 22 she died, twelve days after admission and twenty-two days after the onset of the disease.

As no specific therapy for this disease has been described, when the prognosis became desperate 200 cc. of convalescent serum, obtained from the patient's brother-in-law, was given intravenously in fractional doses, but apparently without benefit. It was ascertained subsequently that convalescent human serum had been used once in the Johns Hopkins Hospital, apparently with good results.

On admission the white blood count was 12,000, with a normal differential count. Forty-eight hours before death the white blood count was 4,000, with 88 per cent polymorphonuclears. Examination of the urine was negative except for a trace of albumin and a few granular casts. Blood culture was negative. The agglutination test, on blood taken during the second week of the disease, was positive at a dilution of 1:40. A guinea-pig, inoculated with whole blood taken from the patient on admission, died with the typical lesions of tularemia. Another guinea-pig, inoculated with pus recovered two days before death from the lesion on the middle finger, died six days after inoculation with lesions typical of tularemia. Bacterium tularense was recovered from the spleen in pure culture on coagulated egg yolk medium. This culture is still being carried on and is being used in other work which will be reported later by one of us. The Wassermann reaction was negative.

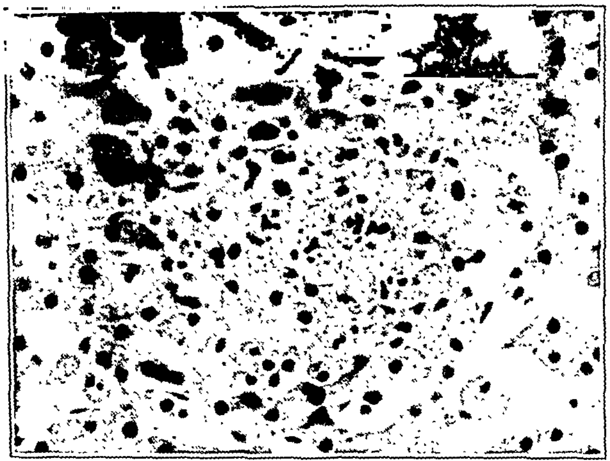

Fig. 4.—Section of liver, showing early tularemic lesion; reduced from a photomicrograph with a magnification of 800 diameters.

Pathologic Examination.—At autopsy, on external examination, the only noteworthy observations were necrotic ulcers on the palmar surface of the distal phalanges of the first, third and fourth fingers of the left hand (fig. 1). When the breast plate was removed, the contents of the thoracic cavity were presented in their normal relations. The lungs were bound down by numerous fibrinous and fibrous adhesions between the visceral and parietal pleurae, and between the parietal pleura, the pericardium and the diaphragm. The middle and lower lobes of the right lung and the lower lobe of the left lung presented numerous discrete or confluent, opaque, yellowish gray, caseous abscesses, with irregular cauliflower borders, varying from 1 to 3 cm. in diameter. The lower lobe of the right lung also presented an early lobular pneumonia, while that of the left lung showed moderate pulmonary congestion and edema. The hilar lymph nodes were moderately enlarged and presented numerous small abscesses similar to those seen in the lungs. The heart was not remarkable. The abdominal viscera were bound together by numerous superficial fibrinous adhesions which were easily broken, leaving the surface of the organs slightly dull and granular. The entire liver and spleen were studded with numerous yellowish, opaque, discrete or confluent abscesses with regular outlines, varying from 2 to 8 mm. in diameter (figs. 2 and 3). On external examination the kidneys appeared pale, swollen and flabby, and on cut section the cortices were irregularly thickened and the renal pyramids were unusually prominent. The lining of the entire gastro-enteric tract was a dull, dirty, grayish pink, and the blood vessels were markedly engorged. The serosal surface of the gastro-enteric tract was dull and granular, as previously mentioned. The pelvic organs were not remarkable except for the dull granular appearance of their serosal covering. The suprarenal glands appeared normal. The abdominal lymph nodes also appeared normal, both externally and on cut section. One enlarged epitrochlear lymph node was removed from the left arm and presented numerous abscesses similar to those seen in the hilar lymph nodes. The organs of the neck and the brain presented no noteworthy manifestations.

The anatomic diagnoses were subacute ulcers of the fingers of the left hand; multiple abscesses (tularemic) of the lungs, liver, spleen and lymph nodes; pulmonary congestion and edema with an early lobular pneumonia; fibrous and fibrinous pleuritis; fibrinous peritonitis; subacute enteritis, and toxic nephrosis.

Bacteriologic Examination.—At autopsy, material from the liver abscesses was collected by Prof. W. B. Wherry and inoculated into each of two guinea-pigs, into one cutaneously, after gentle scraping of the skin, and into the other subcutaneously. The one died on the seventh day and the other on the sixth day after inoculation. Both revealed the typical visceral lesions of guinea-pig tularemia. Pure cultures of Bacterium tularense were recovered on coagulated egg yolk from the spleen of each animal. Dermal inoculation of guinea-pigs with the growth from the egg yolk cultures produced death in six days with the characteristic plague-like visceral lesions.

Microscopic Examination.—The lungs showed discrete or confluent areas of caseous necrosis, with extensive nuclear fragmentation into numerous coarse and fine chromatin granules. In some of the larger and more advanced lesions there was moderate peripheral fibroblastic proliferation and monocytic reaction. The pulmonary tissue also showed moderate congestion and edema. A section from the lower lobe of the right lung showed a confluent lobular pneumonia in which the reaction was chiefly monocytic. The pleura was the site of moderate thickening, and an occasional polymorphonuclear leukocyte and monocyte were noted. In the liver were numerous large and small, discrete or confluent areas of caseous necrosis, with fragmentation of the nuclei into numerous coarse and fine chromatin granules. Surrounding these lesions there was a moderate monocytic reaction and some fibroblastic proliferation. Some of the younger lesions showed only a small focal area resembling caseous necrosis with scattered chromatin granules and an occasional monocyte (fig. 4). This organ also showed a moderate chronic passive congestion with atrophy of the liver cords and beginning fatty infiltration. The spleen, too, showed numerous areas of necrosis identical with those seen in the liver, and likewise intense congestion. The regional lymph nodes contained numerous areas of focal necrosis with peripheral monocytic reaction and fibroblastic proliferation, similar to the lesions previously described. The lymph follicles showed moderate rarefaction and the medulla presented focal areas of hemorrhage. There was also a moderate increase of reticulum. The mucosal surface of the gastro-enteric tract presented moderate congestion of the blood vessels and an occasional focal area of polymorphonuclear

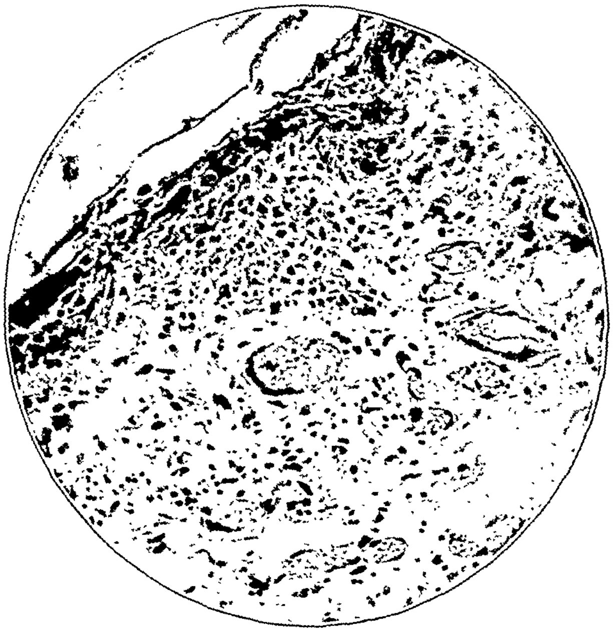

Fig. 5.—Section of serosa of intestine, showing early tularemic lesion; reduced from a photomicrograph with a magnification of 250 diameters.

and lymphocytic infiltration. The serosal surface of the gastro-enteric tract presented a generalized diffuse reaction consisting chiefly of monocytes with an occasional polymorphonuclear leukocyte lying beneath a layer of fibrinous exudate. There were also focal areas of necrosis, chromatin granules and monocytic reaction, identical with the early lesions described in the liver, spleen, lung and lymph nodes (fig. 5). The uterus was not remarkable except for the presence of an exudate on its serosal surface similar to that noted on that of the intestine. No areas of necrosis were seen. Sections of the skin from the index finger showed a small subacute ulcer in which the chief reacting cell was the monocyte. There was also an occasional small area of caseous necrosis with a peripheral area of fibrosis and monocytic leukocytosis. The kidneys showed moderate congestion and edema, with an early acute focal glomerulonephritis. Sections from the bladder showed nothing noteworthy. In sections from the heart were small focal areas of fibrosis, and the muscle fibers appeared swollen and granular. The aorta appeared normal. The suprarenal glands were not remarkable, but there was a moderate monocytic infiltration of the surrounding fat tissue. There was moderate fibrosis and fatty invasion of the pancreas. The thyroid showed focal areas of chronic inflammation. Microscopic diagnoses were subacute ulcers (tularemic) of three fingers of the left hand, with multiple abscesses (tularemic) of the lungs, liver, spleen, regional lymph nodes and serosal surface of the gastro-enteric tract; fibrinopurulent peritonitis; pulmonary congestion and edema, with terminal lobular pneumonia; subacute and chronic pleuritis; moderate fibrosis of the myocardium and toxic myocardosis; chronic passive congestion of the liver, with atrophy of the liver cords; toxic nephrosis and acute focal glomerulonephritis; chronic focal thyroiditis, and subacute gastro-enteritis.

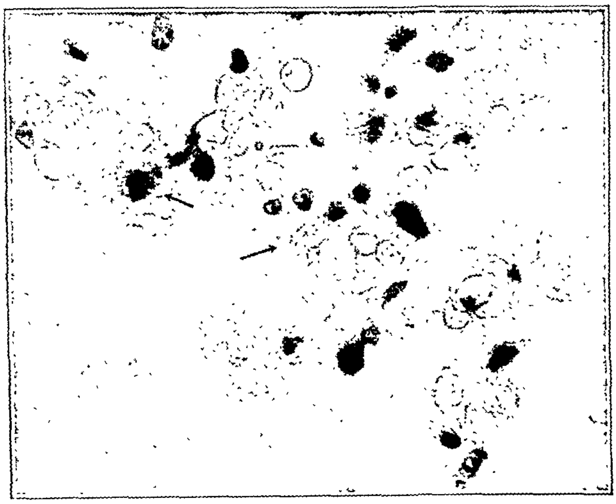

Fig. 6.—Section of lung, showing Bacterium tularense within a macrophage and also a free-lying group; nile blue sulphate stain; reduced from a photomicrograph with a magnification of 1,550 diameters.

TISSUE STAINING

One of us (L. F.) is describing elsewhere a method for staining Bacterium tularense in tissue sections. The essential feature is the use of a saturated aqueous solution of nile blue sulphate. The contrast between the stained bacteria and the cellular background leaves much to be desired, especially for purposes of photography, but the bacteria are readily recognizable.

The chief difficulty in securing good demonstrations in human tissues seems to lie, however, not so much in the color of the dye as in the nature of the pathologic processes. In most of the involved tissues from this case there was an extensive karyorrhexis. Large and small nuclear fragments usually lie wherever the bacteria are found, and the recognition of bacteria in the presence of these fragments is difficult. Occasionally, as shown in the accompanying photomicrograph of the lung (fig. 6), the bacteria occur in free clumps or groups and also within phagocytic cells. The latter distribution is almost characteristic of infected rodent tissues.

Bodies that seem with certainty to be bacteria were found only in the lung. None were found in the lymph glands, kidneys, focal necroses of the intestines, liver, spleen, suprarenal gland, pancreas, heart muscle, aorta, stomach, gallbladder, urinary bladder or brain. These tissues were fixed in Zenker's solution.

SUMMARY

A case of tularemia is reported in which: (*a*) autoinoculation of two fingers of the left hand by contact with the primary lesion on the index finger seems to be highly probable; (*b*) the use of convalescent serum was without beneficial effects; (*c*) lesions of the peritoneum, both focal and diffuse, are described for the first time, and (*d*) a new staining method revealed the presence of Bacterium tularense in tissue sections from certain of the involved organs.

CALCIFICATION IN TUBERCULOSIS OF THE SUPRARENAL GLANDS

ROENTGENOGRAPHIC STUDY IN ADDISON'S DISEASE *

RALPH G. BALL, M.D.
Fellow in Medicine, the Mayo Foundation
CARL H. GREENE, M.D.
JOHN D. CAMP, M.D.
AND
LEONARD G. ROWNTREE, M.D.
ROCHESTER, MINN.

Calcification has long been accepted as evidence of chronic or of healed tuberculous infection. Although other forms of inflammation may occasionally result in calcification, in cases of tuberculosis in which the healing process lags only a little behind the destructive action of the lesion, calcification is extremely common. This was recognized, particularly in regard to lesions of the lungs and the lymph nodes, long before the advent of roentgen rays. Although calcification is not entirely pathognomonic, it almost always indicates tuberculosis, so that in the minds of physicians calcification and tuberculosis are indissolubly associated, especially during the process of healing. It would seem rational, therefore, to assume that calcification might occur in the suprarenal glands of patients with Addison's disease, as the process is frequently tuberculous.

Our interest in the possibility of revealing calcification in the suprarenal glands was aroused in 1925 by a letter from Sir Byron Bramwell,[1] who wrote:

> For more than fifty years I have been interested in Addison's disease, and four years ago I mentioned to Professor George Murray and my son, John Creighton, when going round the Manchester Royal Infirmary, that I thought the x-ray examination of the suprarenal region should disclose the ordinary tuberculous lesion of Addison's disease and would be consequently useful both for diagnosis and prognosis. So far as I have been able to ascertain from physicians and radiologists the

[1] Bramwell, Byron: Personal communication to Rowntree.

only case which has been published is one by Sir Humphry Rolleston[2] in the *British Journal of Children's Diseases*, March, 1914.

Since that time, we have studied numerous roentgenograms with the hope of recognizing the existence of calcification, but without success until, early this year, unexplained shadows corresponding to the region of the suprarenal gland were seen in a roentgenogram taken in a case of Addison's disease.[3]

EVIDENCE OF FREQUENCY OF TUBERCULOSIS AND CALCIFICATION OF SUPRARENAL GLANDS IN ADDISON'S DISEASE

Addison,[4] in his original monograph, reported eleven cases in which necropsy revealed definite pathologic changes in the suprarenal capsules, such as "mottled with tuberculosis," "of a scrofulous nature," "cancerous deposit," and "exceedingly small and atrophied glands." With regard to his first case he said: "The suprarenal capsules were diseased on both sides, the left about the size of a hen's egg, with the head of the pancreas firmly tied down to it by adhesions." Both capsules were "as hard as stones." The accuracy of these observations of the pathologic changes which serve as etiologic factors in Addison's disease is borne out by present-day investigations, and had the rays been available in Addison's day, no doubt he would have described roentgenographic changes in his first case.

Wilks[5] denied the tuberculous nature of Addison's disease, claiming that it in itself represented a disease. Time, however, has proved the correctness of Addison's ideas as applied to most cases. The mycobacterium of tuberculosis has been revealed in sections of strumous suprarenal glands taken from a patient who had Addison's disease but whose other tissues and organs were free from tuberculosis.

Guttman,[6] in a review of a series of 566 cases of Addison's disease, found tuberculosis of the suprarenal gland to be the etiologic factor in 69.72 per cent. He recorded, in order of frequency, changes in the suprarenal glands as follows: (1) bilateral tuberculosis, (2) atrophy, (3) amyloid disease, (4) neoplasms, (5) vascular lesions, (6) fatty degeneration and (7) pyogenic infections. As rare possibilities he enumerated syphilis, metastatic lesions, pressure atrophy, hypoplasia, trauma, metaplasia of bone marrow, and so forth.

Barker[7] of the Mayo Clinic, reported on the pathologic anatomy of the suprarenal glands in twenty-eight cases in which the clinical syndrome of Addison's disease had been present. In twenty-five of these (89 per cent) the lesion was found to be tuberculous on histologic examination, and in the remaining three (11 per cent) it was found to be advanced atrophy. Our necropsy material obtained in thirty-four cases of Addison's disease revealed tuberculosis of the suprarenal glands in approximately 83 per cent.

That tuberculous lesions predominate seems unquestioned. Rolleston considered them to be "the only common cause of Addison's disease . . . the others, with the exception of simple atrophy, may be considered as very rare." Wells[8] estimated that 90 per cent of the cases of Addison's disease are the result of tuberculous destruction of the suprarenal glands and that 10 per cent are the result of atrophy.

Reports in the literature of gross calcification of the suprarenal glands in Addison's disease are not common, and the incidence in large series of cases is not given. Most textbooks on pathology admit the occurrence of calcification. In 1871, Quain,[9] in support of tuberculosis as an etiologic factor, reported the pathologic data in a case of Addison's disease as follows: "The kidneys were healthy, and to them adhered firmly the suprarenal capsules, which were cemented into a hard, calcareous mass on both sides. The condition of the calcified masses in the lungs and in the suprarenal capsules was as nearly as possible identical." Of another case of Addison's disease, seen in the same year, he remarked, "The suprarenal capsules were cretaceous."

In 1899, Bramwell[10] wrote of the pathology of Addison's disease: "In some cases gritty calcareous nodules are present in the midst of the caseous material. In long standing cases the whole capsule may be converted into a cheesy, putty-like or calcareous mass."

Seligman,[11] in 1928, reported the occurrence of four cases of suprarenal calcification in reviewing 1,185 postmortem examinations. In none of the cases had Addison's disease been diagnosed. In forty-six cases of tuberculosis of the suprarenal glands, calcification was not noted. Seligman concluded that the etiologic factor for calcification of the suprarenal glands had not been established. From this standpoint, the comparative frequency of suprarenal calcification in cats, which has been emphasized by Brüschweiler[12] and by Marine,[13] may be considered. The latter stated that the condition is always calcification, and never ossification, and that it occurs more commonly in young animals which have had distemper. The symptoms resemble those seen in suprarenalectomized cats. Marine has expressed the view that a specific toxin of distemper may produce focal degeneration and necrosis, with subsequent deposits, first of fatty compounds, which later change to carbonate and phosphate. The possibility of a specific toxin affecting the suprarenal glands in Addison's disease has been considered previously.

In Barker's report, gross calcification was associated with tuberculosis of the gland in one case; about half the substance of both glands was replaced by calcium salts.

Guttman, in his description of the usual tuberculous lesion which he found in the suprarenal glands, stated that calcification is not uncommonly seen and that formation of bone has been described.

Woolley[14] has reported heteroplastic bone and the formation of the bone marrow associated with tuberculosis in the suprarenal gland in cases of generalized miliary tuberculosis. A case is reported by Newsam [15] of a girl, aged 2 years and 7 months, who had not suffered from faulty development or serious illness until she suddenly went into coma and had convulsions of a clonic type which involved all the extremities, the body and the face. Incontinence and vomiting were also present, without apparent cause. Death followed, after many convulsions, in about fourteen hours. At necropsy, inspection of the suprarenal glands indicated that very little of the cortex remained, and that the entire medulla was replaced by calcified material. In the normal situation of the medulla there were deposits of calcium salts and also spicules of bone and bone marrow containing blood-forming cells. In certain places, the deposits of calcium salts were being replaced by bone.

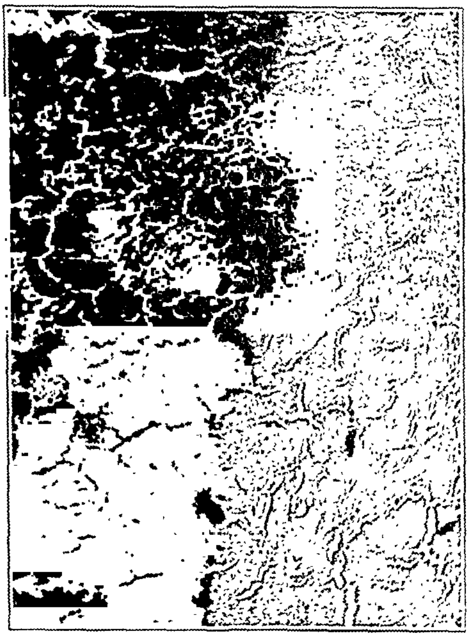

Fig. 1.—Calcification in tuberculous suprarenal gland.

Although many cases of calcification of the suprarenal glands have been reported as the result of tuberculous lesions, data have not been presented to indicate the incidence of association of these two conditions. Examination of the fresh tissue at necropsy ordinarily will disclose only gross calcareous deposits. Histologic examination ordinarily is confined to small blocks of tissue, and unless serial sections of the entire gland are made, small areas of calcification are readily overlooked. Roentgenographic examination is the best method for demonstration of calcification in soft tissues. In doubtful cases, portions in which there is increased density may then be removed, and the presence of calcification may be proved by histologic or by chemical examination. Therefore we have applied this method to study of the material available in the Mayo Clinic.

STUDY OF MATERIAL AT THE MAYO CLINIC

Pathologic Data.—The suprarenal glands were obtained in thirty-four cases which had been listed by the pathologists either as Addison's disease or as tuberculosis of the suprarenal glands. A positive clinical diagnosis of Addison's disease had been made in twenty-three of the cases, and a diagnosis of questionable Addison's disease was made in three other cases. In the remaining eight cases there were tuberculous lesions of one type or another (table 1). The presence of calcification was determined by histologic examination (fig. 1). A second group of suprarenal glands, which had been both grossly and histologically adjudged to be normal was also observed.

Roentgenologic Data.—Both groups were then subjected to roentgenologic examination. Calcification or areas of increased density were not shown in the normal glands. In the pathologic glands there was wide variation in density, with very obvious calcification in certain cases (fig. 2).

Table 1.—*Summary of Material Studied at the Mayo Clinic*

Clinical Diagnosis	Cases	Increased Density in Roentgenograms of Suprarenal Glands Obtained After Death
Addison's disease	23	6
Questionable Addison's disease	3	2
Tuberculous meningitis	2	..
Papilloma of bladder	1	1
Syphilis of the central nervous system; healed tuberculous pleuritis and lymphadenitis	1	1
Pulmonary tuberculosis	1	..
Acute suppurative pancreatitis and peritonitis; healed tuberculosis of the lungs	1	1
Tuberculous pericarditis	1	..
Tuberculosis of the right kidney	1	..
Total	34	11

In some glands there were distinct, isolated shadows indicative of sharply localized calcification. In others there was increase in density throughout the tissue, suggesting a diffuse deposition of lime salts such as could be expected with a high grade of caseation. These features were confirmed by histologic examination of the tissues, as shown in figure 1.

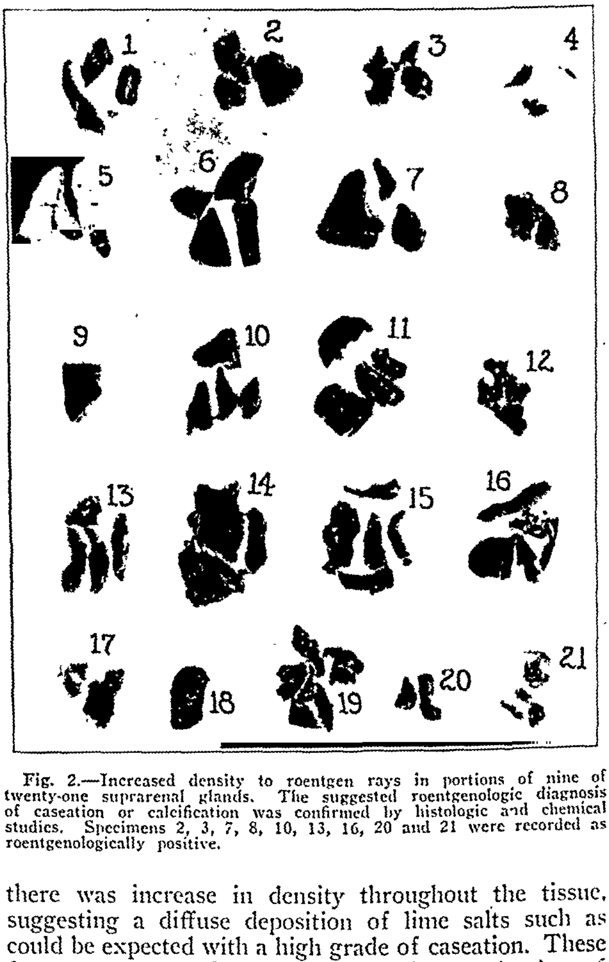

Fig. 2.—Increased density to roentgen rays in portions of nine of twenty-one suprarenal glands. The suggested roentgenologic diagnosis of caseation or calcification was confirmed by histologic and chemical studies. Specimens 2, 3, 7, 8, 10, 13, 16, 20 and 21 were recorded as roentgenologically positive.

[15] Newsam, A. R.: Calcification and Bone Formation in the Adrenals, Rhode Island M. J. 7: 35-38 (March) 1924; abstr. J. A. M. A. 82: 1397 (April 26) 1924.

In reviewing the roentgenograms, only those glands were called positive in which in our opinion it should have been possible to demonstrate increased density during life. It is of interest that in several additional glands there were definite minute calcified portions, which, however, could not in all probability have been demonstrated in life.

Table 2.—*Chemical Analysis of Specimens of Nine Normal Suprarenal Glands*

83.0	0.47	2.77	69	406	14.7	113	664	24.0	0.61

Of the cases in which material was obtained at necropsy, there were twenty-three in which a positive diagnosis of Addison's disease had been made. In six of these, the glands were roentgenographically positive, an incidence of approximately 26 per cent. Of the three cases in which the diagnosis of Addison's disease had been given as questionable, the glands in two were positive, and of the remaining group of patients with miscellaneous tuberculous lesions, the glands of three were positive. There was a total, then, of eleven cases (32.3 per cent) in the entire group of thirty-four cases with roentgenographic evidence of pathologic change in the suprarenal glands, which it seemed reasonable to suppose might have been demonstrated in the living patient if careful studies had been made. Unfortunately, roentgenograms covering the region of the suprarenal glands either had not been taken or were reported negative in routine examinations, and consequently were not preserved for review.

Table 3.—*Chemical Analysis of Specimens of Twenty-Four Diseased Suprarenal Glands*

Water, per Cent	Ash, per Cent		Calcium, Mg. in Each 100 Gm.			Phosphorus, Mg. in Each 100 Gm.			Calcium: Phosphorus Ratio	Evidence of Calcification in Roentgenograms of the Suprarenal Gland

Chemical Data.—That the increase in density of the shadow in the roentgenograms was due to the deposition of calcium salts was further shown by chemical examination of whole glands. The material had been fixed in formaldehyde, and hence it was not possible to make correction for consequent changes in the water content of the tissue, or for the extraction of salts by solution of formaldehyde. Results for the percentage of ash, calcium and phosphate are reported in terms of the weight of the fixed tissue, the dry weight and the ash. Table 2 shows that, in normal tissues, phosphates are present in considerably greater amounts than is calcium; the maximal amount of either is 700 mg. in each 100 Gm. dry weight, with a maximal content of ash of 2.77 per cent.

The chemical analysis of representative portions of twenty-four tuberculous glands studied (table 3) indicated that the composition of fourteen fell within these normal limits. In ten glands the percentage of ash was excessive. In one of the glands in which a calcareous nodule had been dissected out for study, the content of ash increased up to 73.9 per cent of the dry weight of the tissue. In the cases in which the total ash was increased, the calcium-phosphorus ratio varied from 1.85 to 2.28, which is approximately that found in calcium phosphate and in bone. With one exception there were portions of increased density on roentgenologic examination of these ten glands. In addition, there were three other cases in which the roentgenogram gave evidence of small, localized deposits, but these apparently were too small to produce a change in the chemical composition of the gland as a whole.

ROENTGENOGRAPHIC EVIDENCE, IN LIFE, OF SUPRARENAL CALCIFICATION IN ADDISON'S DISEASE

Our observations indicated the presence of calcification in approximately a third of tuberculous suprarenal glands. This immediately raises the question of the roentgenologic demonstration during life from the standpoint of diagnosis and prognosis. In this connection the literature reveals that Rolleston and Boyd in 1914 first observed calcification in the region of the suprarenal glands in a boy, aged 12 years and 9 months, whose history of pigmentation and symptoms dated from ten to twelve months prior to the time of examination. The roentgenographic report, by Melville, reads: "There are very definite calcareous particles in the region of the last rib and suprarenal body on the right side, less definite on the left. There are discrete and dense opacities at the hila of the lungs, suggesting calcified nodules." Rolleston in his discussion of the case expressed the opinion that the suprarenal calcification pointed to obsolete tuberculosis and that this was in accordance with the negative Pirquet reaction which was obtained. He further presumed that the cicatricial contraction in the calcifying suprarenal glands, rather than active tuberculosis, was responsible for the recent appearance of symptoms of Addison's disease.

In 1928, Gellerstedt and Hjelm[16] reported the case of a boy, aged 6 years, in whom they observed roentgenographically a fine coral-like shadow of calcification above the right kidney. At necropsy the deposit of calcium was found to be present in a ganglioneuroma of the suprarenal gland.

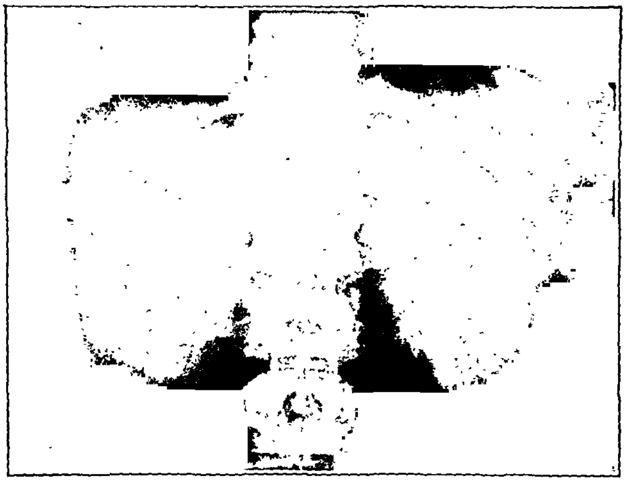

Fig. 3 (case 1).—Shadows in regions of left and of right suprarenal glands.

In 1930, Pescatori[17] reported a case with the clinical syndrome of Addison's disease, in which he was able to demonstrate in the roentgenogram what appeared to be small deposits of calcium salts in the left suprarenal gland. In this article he cited two cases of Addison's disease reported by Perussia, in which suprarenal shadows of calcification were observed. In one of these cases the calcification of the suprarenal gland was confirmed at necropsy.

Additional cases of Addison's disease, in which the roentgenogram contained shadows in the region of the suprarenal glands, have been reported by Thompson,[18] by Schatzki,[19] and by us.[20] Since our first report, we have been informed of similar observations by Snapper,[21] Allbright[22] and Bell.[23]

It is our purpose to present six additional cases of Addison's disease in which roentgenographic shadows in the region of one or of both suprarenal glands have been observed. Detailed accounts of these cases and their response to treatment have been previously reported by us.[24]

REPORT OF CASES

Case 1.—A man, aged 20, who was admitted to the Mayo Clinic, Dec. 31, 1930, complaining of weakness and pigmentation of the skin, appeared to be exhausted. The skin was of a light olive color, with darker, mottled areas on the exposed surfaces, about the pelvic girdle, and on the extensor aspect of the arms. The nipples were almost black, and the genitalia and anus were deeply pigmented. There were a few scattered freckles, and some pigmented areas on the palms, soles and buccal mucous membrane. The skin was smooth, unwrinkled, and of a silky texture. Roentgenograms of the thorax gave evidence of old tuberculosis of the right upper lobe. In roentgenograms of the kidneys there were bilateral shadows in the suprarenal regions (fig. 3). A clinical diagnosis of Addison's disease was made.

Case 2.—A man, aged 45, who came to the clinic with the chief complaint of having felt exhaustion for two or three years, was poorly nourished and had marked, diffuse pigmentation of the skin. There was increased mottling and freckling on the exposed surfaces, and a great deal of pigmentation around the lips and mouth. Roentgenographic examination disclosed well marked bilateral shadows in the region of the suprarenal glands (fig. 4). A clinical diagnosis of Addison's disease was made.

Case 3.—A woman, aged 62, brought to the clinic by her son, a physician, who had made a diagnosis of Addison's disease, had been in good health until nine months before, when darkening of the skin over the face and hands had been noted by her husband. She was poorly nourished, with deep brownish-olive pigmentation of the entire skin, somewhat deeper over the exposed surfaces. There were a few dark brown scattered freckles. The buccal mucous membrane contained numerous patches of brown pigment.

Roentgenologic studies of the thorax gave negative results, but roentgenograms of the region of the suprarenal glands disclosed a definite shadow on the right side (fig. 5).

Case 4.—A man, aged 26, who was admitted with a complaint of weakness and dyspnea on exertion, was well developed, with diffuse, olive tan pigmentation over the entire body, and a deeper brown coloring of the nipples, genitalia, axillae, and an abdominal surgical scar. Pigmentation of the mucous membrane of the mouth could not be found. Numerous scattered brown and black freckles were present over the face and arms, and a small area of brownish pigmentation was seen in the sclera of the right eye. Roentgenograms of the region of the suprarenal glands disclosed no abnormality on the left side but a small area of increased density on the right (fig. 6).

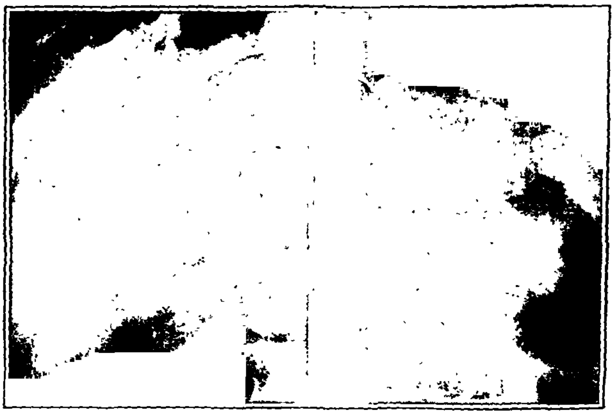

Fig. 4 (case 2).—Shadows in regions of left and of right suprarenal glands.

Case 5.—A man, aged 49, who came to the clinic complaining of fatigue and generalized brownish pigmentation of the skin, presented definite accentuation of the color about the genitalia, anus and axillae. There was diffuse pigmentation of the mucous membrane of the mouth and scattered areas on the lips. Numerous black freckles were present, particularly over the arms. A faint roentgenologic shadow of calcification was apparent *in the region of the left suprarenal gland*, with less distinct calcification on the right (fig. 7).

M. A. **97:** 1446 (Nov. 14) 1931.

Case 6.—A woman, aged 22, who came to the clinic complaining of weakness, periods of nausea with some vomiting, and marked brownish pigmentation of the skin, had considered herself in excellent health until four months previously. Examination disclosed diffuse cutaneous pigmentation, which was accentuated about the genitalia, anus, axillae and nipples, and points of pressure on the feet. Patches of pigmentation were present on the lips, gums and buccal mucous membrane. The systolic blood pressure was recorded as 75 and the diastolic as 55 mm. of mercury. A clinical diagnosis of Addison's disease was made. Roentgenograms of the suprarenal regions revealed marked bilateral calcification (fig. 8).

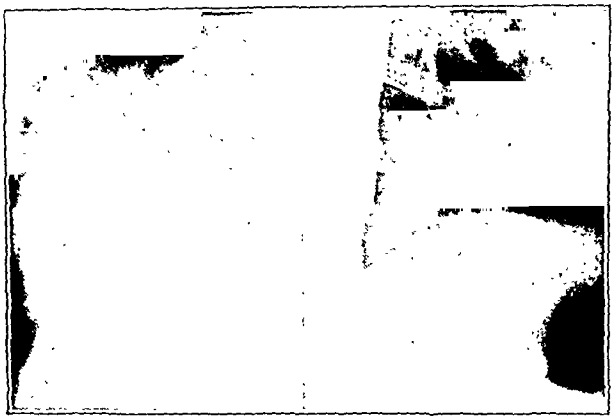

Fig. 5 (case 3).—No shadow in left suprarenal region, but shadow present in corresponding region on right side.

ROENTGENOSCOPIC OBSERVATION, IN LIFE, OF SUPRARENAL CALCIFICATION IN ADDISON'S DISEASE

Calcification in the suprarenal regions was very distinct in the roentgenograms of case 6. Study of the roentgenograms suggested the possibility, not only of determining the normal range of motion of these glands, but also of their observation under the roentgenoscope. A roentgenogram was taken during expiration with the patient lying on her back. The gland on the right side was somewhat lower than that on the left, the upper border appearing at the level of the middle portion of the twelfth thoracic vertebra, the lower border extending down to the middle portion of the body of the first lumbar vertebra. The medial border was in juxtaposition to the spine. The gland on the left side lay 1.5 cm. higher, with its medial border along the lateral edge of the psoas muscle. During deep inspiration both glands descended 2 cm. caudally.

The patient was observed under the roentgenoscope. The left suprarenal gland could not be distinguished with certainty, but the right was distinctly seen. It was observed to descend caudally during inspiration and to ascend to its original position with expiration. The movement of the gland during the respiratory cycle was marked on the roentgenoscopic screen and traced on paper. The position of the gland and the extent of its movement corresponded precisely with that observed in the roentgenograms.

This, so far as we know, is the first time that the suprarenal gland has been observed fluoroscopically. Because of the calcification in this patient with Addison's disease, we were able not only to visualize the gland, but also to determine the change in its position during inspiration and expiration.

ROENTGENOGRAPHIC EVIDENCE OF SUPRARENAL CALCIFICATION WITHOUT ADDISON'S DISEASE

In order to ascertain the incidence of shadows in the region of the suprarenal glands in the absence of Addison's disease or of tuberculosis, a series of 300 roentgenograms of patients of varying ages, and with miscellaneous complaints, was carefully reviewed. In one instance a shadow was observed in the region of the left suprarenal gland. The patient was a man, aged 23, whose condition had been diagnosed as "functional enuresis" and dipsomania. No mention was made of pigmentation, exhaustion or gastro-intestinal complaints. Tuberculous lesions were not found. The blood pressure was 100 systolic and 70 diastolic.

A roentgenogram of a patient suffering from disease of the gallbladder and from obesity was recently called to our attention. There was what appeared to be a definite area of increased density in the right suprarenal region. A clinical diagnosis of Addison's disease could not be made. However, because of the evidence of a lesion in the region of the right suprarenal gland, this patient might be considered as being in the preclinical stage of Addison's disease stressed by Rowntree, Greene, Swingle and Pfiffner. We have previously pointed out the danger of operative and surgical procedures of any kind in a case of Addison's disease. In cases such as this, evidence of lesions of suprarenal glands must be considered in evaluating the operative risk, and, if operation should be undertaken, a prophylactic or supporting course of treatment with cortical hormone would be desirable.

Because of the intimate association of tuberculosis elsewhere with similar lesions in the suprarenal glands, a group of 100 pyelograms of tuberculous kidneys was studied. In one case a shadow was seen in the region of the left suprarenal gland; the patient, aged 41, had tuberculosis of the left kidney and old pulmonary tuberculosis. There was nothing in the history to suggest suprarenal insufficiency. Left nephrectomy was performed and convalescence was satisfactory, which emphasizes the fact that a unilateral lesion does not necessarily mean suprarenal insufficiency.

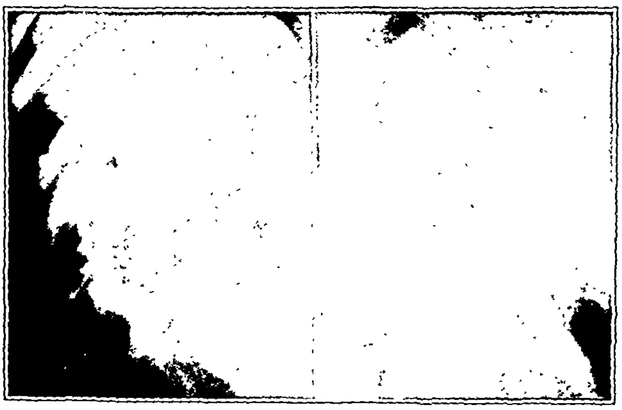

Fig. 6 (case 4).—No shadow in left suprarenal region, but small shadow in corresponding region on right side.

The roentgenograms of thirty-five patients with Pott's disease of the spine were also reviewed, and in this group no shadows in the region of the suprarenal glands were observed.

We report a fourth case, which is interesting because, from the clinical standpoint, pathologic changes in the suprarenal glands were suspected, and when roentgenograms were obtained there was evidence of increased density on the right side:

A woman, aged 25, who came to the clinic with a chief complaint of headache and head noises had undergone thyroidectomy three months prior to admission, although no history of hyperthyroidism could be elicited. Since the operation, she had complained of a variety of bizarre sensations but particularly of headaches and head noises. The headache was described as a sensation of pressure, practically constant, which involved the entire head. The head noises were likened to whistling, the ringing of curfew bells, or a roaring sound. She had a very definitely masculine appearance. Her mother, when questioned, felt that she could not be sure that the patient had become so recently, but she was positive that the growth of hair about the breasts and abdomen had developed in the last five years. Menstruation had begun at the age of 12 years and had been normal until two years prior to admission, but flow had been very scanty since. The mother stated that the girl had always been quiet and studious, had had no interest in boys, and from an early age wanted to enter the convent. There were many coarse black hairs over the jaw, chin and upper lip. The breasts were small and the nipples surrounded with hair. The pubic hair was thick and coarse, of masculine distribution, and extended in the median line to the umbilicus. The forearms and legs were also hairy. There was no abnormality of the external genitalia. The skin was dry and flaky. A scar left after thyroidectomy was present, and no thyroid gland could be palpated. The right ear appeared to be totally deaf, and hearing in the left ear was markedly diminished. Examination of the eyes gave negative results. A right rectus operative scar was present. An indistinct mass could be palpated in both renal regions but could not be identified; there was definite tenderness on the left side. The reflexes were active. Neurologic examination was essentially negative. The patient apparently suffered from an anxiety neurosis.

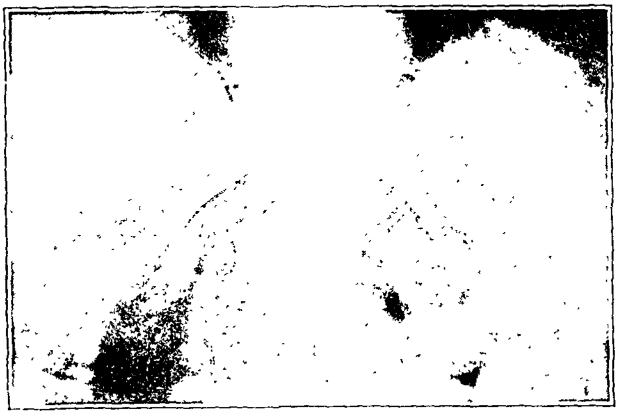

Fig. 7 (case 5).—Shadow in the left suprarenal region; no shadow in corresponding region on right side.

Urinalysis and the Wassermann test of the blood gave negative results. The number of erythrocytes and leukocytes and the chemical values of the blood were repeatedly normal. The basal metabolic rate ranged from —15 to —5. Testing of the renal function gave satisfactory results. Roentgenograms of the head and thorax were negative. Roentgenograms of the kidneys, ureter and bladder disclosed sacralization of the last lumbar vertebra on both sides, and spina bifida occulta of the sacral segment. The kidney shadows were of normal size. A roentgenogram of the suprarenal areas revealed increased density in the region of the right suprarenal gland. This raised the question of a possible tumor of the suprarenal gland, but the severity of symptoms did not warrant immediate exploration.

COMMENT

It would appear from our study that lesions of the suprarenal glands are roentgenographically demonstrable in a certain proportion of cases in which there is tuberculous involvement. The more chronic pathologic changes, with fibrocaseation or calcification, appear to be most easily demonstrated roentgenologically. In the majority of cases the active disease process probably destroys sufficient cortical tissue to cause death before fibrocaseation or calcification occurs. In the cases of Addison's disease due to simple cortical atrophy, the roentgenograms obviously would be negative. From a clinical consideration of the group of cases that is sometimes called "borderline" or "questionable" Addison's disease, positive roentgenographic evidence would be a valuable link in the chain. It would seem advisable, in that group of cases in which many symptoms of Addison's disease are present and yet in which the clinician hesitates to make a diagnosis of Addison's disease, carefully to study the suprarenal region roentgenologically.

Roentgenologic demonstration of calcification in the region of the suprarenal glands may be of diagnostic significance in a case of suspected or questionable Addison's disease. On the other hand, it must be remembered, as shown in table 1, that suprarenal tuberculosis of marked degree, especially if unilateral, may be present without sufficient clinical evidence of suprarenal insufficiency to warrant a diagnosis of Addison's disease.

In cases in which the diagnosis of Addison's disease is unquestioned and there is a definite history or evidence of tuberculous infection, the lesion in the suprarenal glands is almost certainly of a tuberculous nature. It has been observed, by Rolleston and by Bramwell, that the cases with active tuberculous etiology respond less satisfactorily to treatment than do those with simple atrophy. This is the impression we have obtained. If active lesions are present in the lungs, we attempt to arrest or heal them. A similar attempt might be considered in regard to the suprarenal glands, although Rolleston's case should be kept in mind, in which the cortical insufficiency was attributed to cicatricial contraction in the calcifying glands. Final conclusions cannot be drawn from observation of only six cases, but the advisability of attempting to promote healing by means of such measures as a dietary regimen, viosterol, calcium, the judicious use of parathyroid extract or roentgen rays is to be considered. The results might be studied by making roentgenograms of the suprarenal regions during and after treatment.

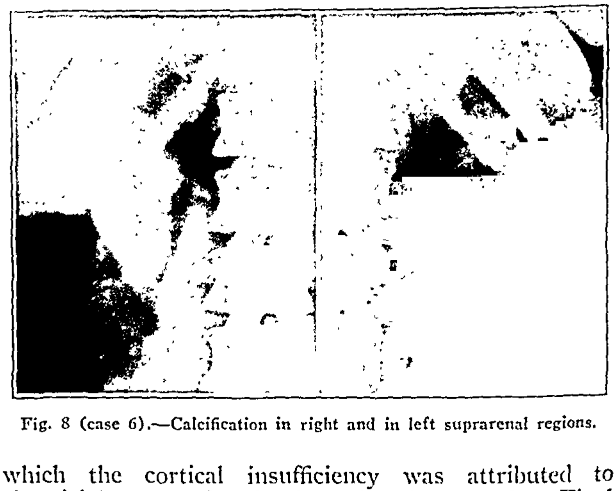

Fig. 8 (case 6).—Calcification in right and in left suprarenal regions.

In reporting six cases of Addison's disease with roentgenographic shadows in the region of the suprarenal glands, we hope that further interest will be aroused in the subject. From a study of the available pathologic material it appears probable that in a considerable percentage of cases calcification is present and that this can be roentgenologically demonstrated in life. It is suggested that such a demonstration may be of diagnostic and prognostic significance, and it is urged that roentgenographic studies be made in cases of suspected or proved Addison's disease.

DIVERTICULA OF STOMACH AND SMALL INTESTINE *

AMBROSE L. LOCKWOOD, M.D., C.M., F.A.C.S., F.R.C.S. (Cam.)
TORONTO

Gastric diverticulum is a rare condition but does occur, about forty-five cases having been reported in the literature. The majority have been found on the posterior wall of the stomach, close to the lesser curvature and the cardio-esophageal juncture and in such a position are as a rule inaccessible to surgical treatment. A small percentage have been found close to the pylorus on the posterior wall. Only one case has been reported on the greater curvature, and one on the anterior surface of the stomach. The condition causes distress simulating a gastric ulcer, and the diagnosis depends on thorough fluoroscopic examination.

Because of the inherent tendency of irritative lesions of the stomach to develop into malignant conditions, and because of the fact that three cases at least of carcinoma developing in diverticula have been reported, the condition should undoubtedly be dealt with surgically if it can be readily approached. Otherwise, a dietary regimen must be relied on.

MECKEL'S DIVERTICULUM

I will point out briefly the advisability of searching for Meckel's diverticulum at operation in all patients with atypical abdominal distress, particularly in interval appendectomies and in upper abdominal procedures in which the symptoms point to a small bowel problem but in which at operation not enough pathologic change is found to account for the patient's history of distress. I recently experienced the pleasure of finding a large, inflamed Meckel's diverticulum in a patient explored for atypical discomfort in the upper part of the abdomen, but without any pathologic condition being found until the small bowel was followed down, and an acutely involved Meckel's diverticulum was found. A careful history of the symptoms will often point to such a possibility, as it did in this case.

DUODENAL DIVERTICULA

I wish particularly to call attention to the question of duodenal diverticula. Although for many years diverticulum of the esophagus and the bladder, and Meckel's diverticulum have been recognized and dealt with surgically, duodenal diverticulum, an equally distressing condition, occurring more commonly, has been relatively overlooked all these years as a surgical entity

Prior to 1912, not more than 100 cases had been reported, and these were discovered at operation or necropsy. Case,[1] of Battle Creek, was the first to diagnose the condition roentgenologically, and in 1913 he reported four cases. In 1920, he could find only eighty-five cases so diagnosed. MacLean,[2] an astute surgeon of Winnipeg, reported sixteen cases in 1923, of which four were dealt with surgically The Mayo Clinic reported nineteen cases, discovered at operation or necropsy.

Up to the present, approximately 357 cases have been diagnosed roentgenologically, and sixty-six patients have been operated on. At the Lockwood clinic, fifty-one cases have been diagnosed roentgenologically and twenty-two of these have been dealt with surgically, and it is my firm conviction that at least thirty-eight patients should have been so treated and will yet return for surgical intervention. Various authors report the incidence of duodenal diverticula as 2.2 per cent of routine necropsies. We have found them in approximately 1.7 per cent of routine gastro-intestinal roentgenologic examinations.

Duodenal diverticula are probably of two types, congenital and acquired. The so-called congenital or developmental type occurs within 3 cm. of the ampulla of Vater, usually proximal to it, about the opening of the common bile duct and as such frequently involves the head of the pancreas. They possibly occur in Keith's weak points in the bowel or in the congenital buds of Lewis and Thyng. The mucous and submucous coats are involved. It is a question whether many so placed demand surgical treatment.

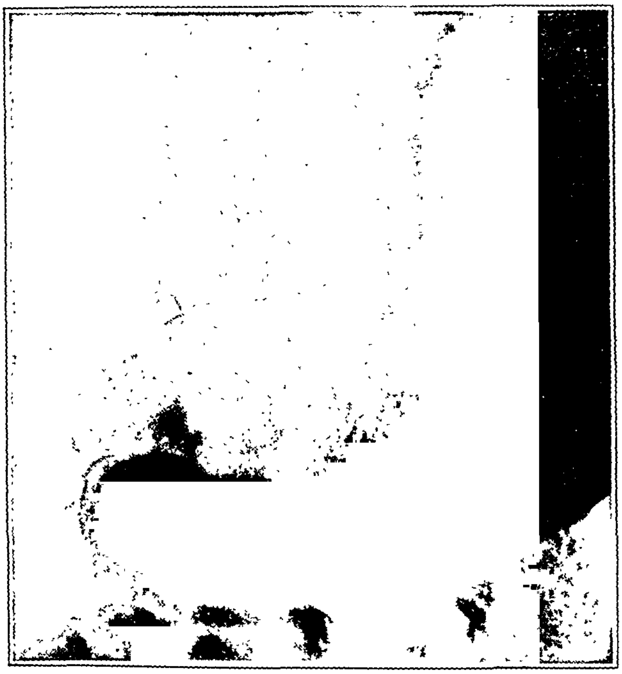

Fig. 1 (Mrs. H. V.).—Duodenal diverticulum of first part with partially loculated sac, associated with pain after eating. The patient was operated on and the sac found, freed and resected

The acquired type has generally been supposed to be due to a "blow-out" from pressure within the bowel, of the contracting scar tissue about a healed ulcer. A hernia occurs with pouch formation. The pouches become globular in outline and on being followed roentgenologically they are seen to enlarge gradually.

---

* Read before the Section on Gastro-Enterology and Proctology at the Eighty-Second Annual Session of the American Medical Association, Philadelphia, June 12, 1931.

[1] Case, J. T.: Diverticula of Small Intestine, Other Than Meckel's Diverticulum, J. A. M. A. 75: 1463-1470 (Nov. 27) 1920.

[2] MacLean, N. J.: Diverticulum of the Duodenum, with Report of a Case in Which the Diverticulum Was Imbedded in the Head of the Pancreas, and a Method for Its Removal, Surg., Gynec. & Obst. 37: 6-13 (July) 1923.

All the coats of the bowel are involved so that only the mucous and serous coats remain intact, and ulceration and perforation have been found in them. Although it has been supposed that they develop from the border of a healed or healing duodenal ulcer, nearly three fifths have occurred in the second portion of the duodenum, and one fifth in the third portion, where ulcer is not commonly found. They must not be conflicted with the pouching that takes place with some penetrating duodenal ulcers. None of the latter are included in our cases. In addition, signs of an old scar at the ostium have not been found in any of our cases at operation. It is more probable that they occur about the blood vessels as they enter and leave the coats of the intestine. The great majority develop on the inner curvature of the bowel, just posterior to the reflection of the peritoneum. Two of our group have been found on the outer curvature of the second portion, and one directly anteriorly on the second part. On the third part they were found on the upper border and tend to fall down behind the intestine. All have been retroperitoneal except the one on the anterior aspect of the second part of the duodenum.

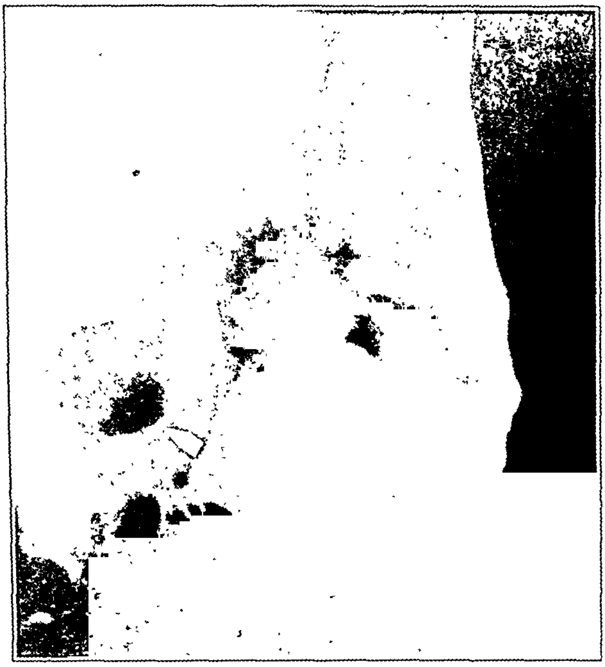

Fig. 2 (A. E.).—Duodenal diverticulum of the second part; nineteen years' history of abdominal trouble, including a gastro-enterostomy which failed to give relief. The patient was operated on and the diverticulum was dissected out and removed. Since operation she has been entirely free from trouble.

They vary in size from not more than 1 cm. in diameter to from 8 to 10 cm. in diameter. One has been reported which was found at necropsy, opening from the inner border of the second portion and hanging over the brim of the pelvis, that contained more than 1,000 cc. of fluid. Approximately three fifths were single and two fifths were multiple. They may have a small opening into the bowel with a long neck to the sac, or they may have a wide ostium that readily admits one or two fingers. In the first portion of the bowel a wide opening is more common, whereas in the second and third portions a narrow opening is found. They may occur at any age but are more common in patients past middle age.

SYMPTOMATOLOGY

A definite symptomatology is being developed for the condition. Patients complain of pain in the epigastrium directly over the diverticulum immediately after eating. The pain varies in type and intensity, depending on the site of the diverticulum, the size of it, whether or not ulceration, perforation or retention exists, and the nature of the foods ingested. The pain is frequently quite severe and is associated with a sense of fulness and distention locally, but without bloating, as seen in cholecystitis. Patients frequently complain of a bursting sensation about the area of the sac. Deep soreness usually is complained of and may be transmitted through to the back. Patients can usually place a finger directly over the site of the pain. When two diverticula are present they will invariably designate the two distinct sites of the pain. The history of pain and soreness extends over many years. There are no periods of well being as with duodenal ulcer. The "pain, food-ease" syndrome of duodenal ulcer does not exist. The pain may be relieved somewhat by the belching of gas and the taking of soda but is more completely relieved by vomiting, which is frequently induced. Patients dread food and avoid it, and are better when they have not eaten at all. As a result, the majority of patients have lost weight, become anemic, are generally debilitated, and develop that peculiar distressing mental outlook that characterizes patients who for a long time have not been able to eat the types of food they enjoy.

The pathognomonic symptoms are as follows:

1. A long history of epigastric distress without periods of well being.
2. Pain (*a*) always in the same position; (*b*) aggravated by food immediately after eating; (*c*) relieved only by vomiting, belching of gas, or the avoiding of food; (*d*) of a bursting type directly over the sac.
3. The finding of the diverticulum roentgenologically.

ROENTGENOLOGIC EXAMINATION

The symptoms point to the condition, but expert fluoroscopic examination must be relied on for actual diagnosis and localization of the sac. The duodenum should be thoroughly filled with barium throughout, and a careful search made for diverticula. When the sac is localized, its position and size and the exact site of the ostium should be determined. Plates should then be taken to confirm the diagnosis and for record purposes. Retention has been repeatedly demonstrated in the sac. Patients should be examined for retention at the end of twenty-four and forty-eight hours. Some roentgenologists have advised the filling of the duodenum through a duodenal tube passed well into the bowel. This procedure would be valuable for studying the diverticulum and has the advantage of permitting the duodenum to be filled without any barium in the stomach to obscure the field. It would be particularly useful in diverticula of the third portion of the bowel.

COMPLICATIONS

The condition is frequently associated with cholecystitis, duodenal ulcers and recurring appendicitis.

Ulceration, bleeding and perforation of the sac may occur. I have previously reported the perforation of a diverticulum on the outer curvature of the second portion into the gallbladder and colon while the patient was on a dietary regimen. The patient, a man, aged 63, was very ill for six weeks, but surgical intervention was ultimately successful.

TREATMENT

In our experience the treatment should be surgical if distress persists in spite of adequate dietary control. Diet may benefit the condition somewhat but does not cure it. Frequently, patients are not relieved at all by a dietary regimen. Patients with retention in the sac rarely respond to medical care. Ulceration, bleeding and perforation have occurred while patients were on palliative treatment.

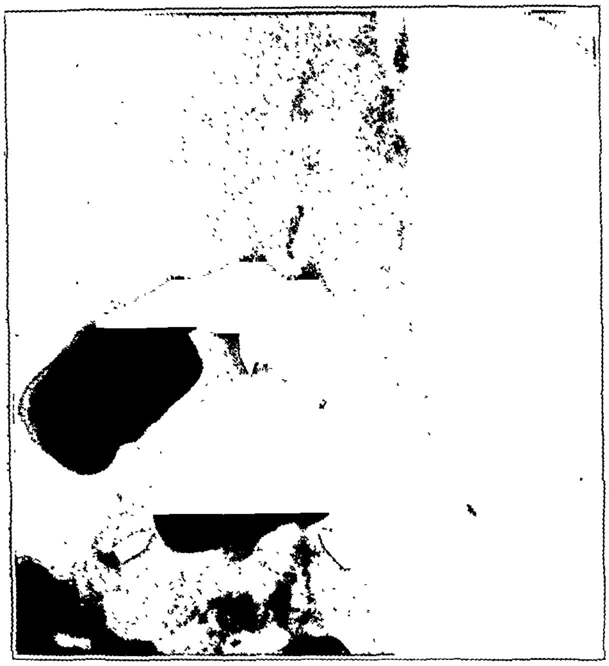

Fig. 3 (H. T.).—Duodenal diverticulum of the second and third parts. The patient, aged 78, with twenty years' history of "stomach trouble," had had extensive dietetic treatment, which failed. She insisted on operation. The diverticula were easily located and excised. She has had complete relief since.

Surgical treatment consists in dissecting and freeing the sac; the neck of the sac is then crushed in a pair of curved forceps, and ligated, the sac is severed and the pedicle is oversewed and buried.

The roentgenologist should be present at the operation and be prepared to designate the exact location of the diverticulum. Blood vessels are distributed over the sac, materially facilitating recognition of the diverticulum at operation. If a sac in the first or second portion of the duodenum is not readily discovered at operation, a small incision should at once be made in the duodenum, a finger inserted, and the opening into the sac located from within the bowel. The finger is then passed into the ostium, which simplifies the freeing of the sac from its attachments. Great care must be taken in freeing the sac, as the wall is so thin. Thanks to the valuable suggestion of MacLean,[2] a diverticulum on the third portion of the duodenum can readily be exposed by elevating the transverse colon and mesocolon, and, by making a small opening at the reflection of the peritoneum posteriorly, one comes directly on the duodenum. In this position, the diverticulum comes off the upper posterior border of the bowel, retroperitoneally, and drops behind the duodenum. The sac should be exposed from above, dissected free, and then removed. While it was suggested that a drain should be left down to the third portion of the duodenum, I think it is unnecessary and should be avoided.

Occasionally if a duodenal ulcer is present and the sac is on the first portion of the duodenum, it may be advisable, if the sac is small, to rely on a gastro-enterostomy to relieve the distress rather than to extend the operation by dissecting out the sac as well.

Patients are immediately relieved of their complaint by surgical treatment. We have had no deaths, serious postoperative sequelae, or recurrences of the diverticula.

CONCLUSION

This interesting subject, which has been largely overlooked, is a definite pathologic entity, is distressing in a high percentage of cases, and responds somewhat to dietary treatment; *but it frequently requires surgical* measures for complete relief. It should be sought for in all routine gastro-intestinal roentgenologic examinations, and particularly in all patients with atypical distress of the upper part of the abdomen. It occurs particularly in patients past middle life; it is a progressive condition, and spontaneous cures do not occur.

164 Bloar Street, East.

ABSTRACT OF DISCUSSION

Dr. Lewis Gregory Cole, New York: I first observed this lesion in 1910 and described it as dilatation of the ampulla of Vater. Case set me right on this as being a diverticulum perivaterans. By 1921 Roberts and I had assembled thirty-seven cases, eliminated from this statistical study. These are now found so frequently that unless the stoma points up and the pouch contains barium for a long time they are not considered of clinical significance. The speaker maintains that this lesion causes the bursting sensation. My patients do not complain of a bursting sensation. So insignificant a lesion should not lead to so serious an operation with so high a mortality.

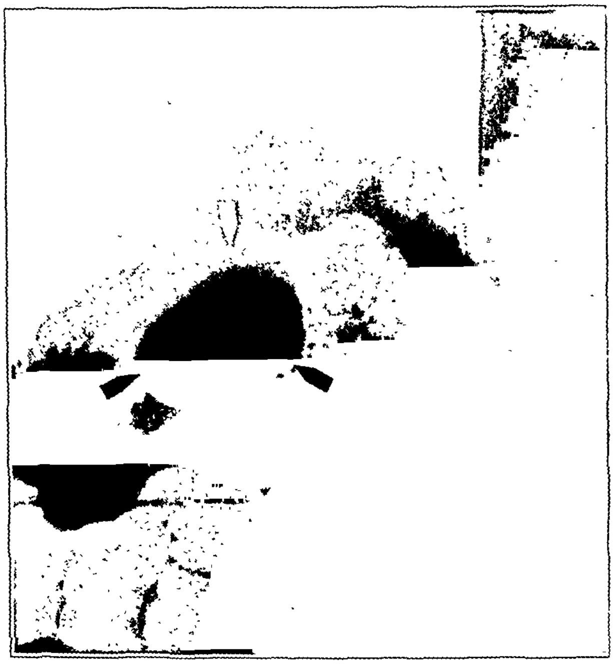

Fig. 4 (O'L.).—Duodenal diverticulum of the second part with ulcer of the first part; symptoms those from the ulcer; six hour retention in the sac. Operation was performed and gastro-enterostomy done. The sac was large and thin-walled and was invaginated and oversewed.

Dr. Fred W. Rankin, Rochester, Minn.: In the course of routine colon examination, that is, examination of colons of people who have symptoms referable to their intestine, one sees in 5 per cent of the cases a single diverticulum or multiple diverticula, and these are *mostly* in the sigmoid. In the left colon they are less frequent and in the cecum they are rare; in the small intestine they occur sporadically throughout its entire length but in nothing like the number in the colon. I think that as one approaches the duodenum they probably occur more frequently than in the jejunum and the ileum and very rarely in the stomach, and quite rarely in the esophagus. I have followed the usual custom of dividing these sacculations into the congenital and the acquired variety. In the course of a routine examination at necropsy over a period of two years, Robertson found that the incidence of the so-called developmental or congenital variety of duodenal diverticula was a little over 2 per cent. In no case of the twenty-six diverticula discovered during this period of examination and reported by Nagle in 1924 was there any evidence of associated inflammatory lesion in the diverticulum. In a relatively large series of gastro-intestinal operations I have had only nineteen cases of diverticulum of the duodenum in which exploration has been done and I think I am correct in saying that all of these nineteen explorations were made for symptoms which I believe to be due to other organic lesions rather than the diverticulum. In this group of nineteen cases, fourteen were associated with duodenal ulcer which I assumed was the cause of the lesion; three of them were associated with cholecystitis with stones, and in the remaining case there was a fistula formation between the gallbladder and the duodenum. This acquired variety I think is almost invariably due to scar tissue formation, scar tissue contraction. It always occurs on the inner border of the duodenum, and the pull from the contraction of the duodenal ulcer, which in most instances is situated on the opposite border, is sufficient to produce the pouching as it is found. Pathologically these acquired diverticula of the duodenum always contain the four coats of the bowel in contradistinction to the congenital type, which runs true to form throughout the entire gastro-intestinal tract and is a hernia of the mucosa and submucosa through the musculature of the bowel wall. It is a good rule to follow, in a diverticulum anywhere in the gastro-intestinal tract, that surgery should be advocated for the extirpation or relief of symptoms only in the presence of complications. I have long since given up extirpations of the large intestine for those not producing symptoms, and my own experience with the diverticula of the stomach is limited to one case. I have not operated on a duodenal diverticulum for symptomatology except in the presence of a duodenal ulcer.

Dr. Ambrose L. Lockwood, Toronto: In the twenty-two cases in which operation has been performed in this group, in only two was there sufficient gallbladder disturbance to justify removal. One patient had stones and the other did not. Of the whole group only three had duodenal ulcers, with no complications whatever. I have been for twenty years greatly interested in gastro-enterological problems. As surgeons and physicians we do not have to live with patients from the roentgenologic point of view but have to treat them daily and keep them free of distress. The shortest interval these patients were on a diet was four months. Some were on a diet for fifteen months. I should be interested to know how many patients Dr. Cole has found with duodenal diverticula whom he has followed and been responsible for treating and keeping free of distress. The multiple diverticula such as he has shown I purposely did not discuss, nor do I think any surgeon of repute today would attempt to deal with such a case. Possibly one, or two diverticula at the outside limit, should be dealt with surgically. In one patient at autopsy nine different diverticula were found in the second and third parts of the duodenum. I also made the statement that I believe thirty-eight of the total should have been dealt with surgically and these patients I hear of or see frequently. They still have their distress but I think that most of them will eventually be operated on. May I point out that of that sixteen, five had previous gallbladder operations, three gastro-enterostomies, and all but four had the appendix removed but still have the distress in the one point. I make no apology whatever for these twenty-two cases in which I have operated. I am only sorry I could not induce the other sixteen patients to have the operation. I am keeping in close contact with them and hope ultimately to be able to persuade them. I should like to point out that the roentgenologist, whom I always have present at the operation for such conditions, is present to designate the site of the diverticulum only, but not as a surgical assistant. He is there to advise about the condition, which I believe is good practice.

POUCHES OF THE PHARYNX AND ESOPHAGUS *

A. S. MACMILLAN, M.D.
BOSTON

My object in this paper is to review the literature on diverticula of the pharynx and esophagus, to mention their probable mode of development, to call attention to the frequency of their occurrence, to discuss their diagnosis and differential diagnosis, and to add an additional twenty-three cases as studied in the Esophageal Clinic at the Massachusetts Eye and Ear Infirmary.

A diverticulum may be defined as a blind pouch that has developed from a viscus or normal canal and may consist of one or more layers of the part involved.

BRANCHIAL CLEFT ANOMALIES

Branchial cleft anomalies must be mentioned in this paper to complete all the pouch formations in the pharynx.

The only congenital diverticula in this region are those of branchial cleft origin. Only rarely do they cause obstruction and contain food. In one patient examined there were two lateral pharyngeal pouches and one posterior, the two lateral pouches probably being the remains of the third or fourth branchial clefts, which open at about the level of the pyriform sinuses. The opening of the second branchial cleft is usually just behind the tonsil and not uncommonly has an external fistula opening in front of the sternocleidomastoid muscle just above the clavicle. The most commonly recognized diverticula of this part are those occurring in the pharynx as the result of a protusion of the lower pharyngeal mucosa through the fibers of the inferior constrictor.

PHARYNGEAL DIVERTICULA

The consideration of pharyngeal diverticula has been the subject of scores of papers in which hundreds of cases have been reported and on which the authors fairly well agree.

From an historical standpoint, the first case reported was by Ludlow,[1] a surgeon of Bristol, England, in 1764, 167 years ago. He referred to it as "a case of obstructed deglutition from a preternatural dilatation of, and bag, formed in the pharynx."

The next case was reported twenty-two years later by Granella.[2]

In 1878, 114 years later, Zenker and von Ziemssen[3] reported five cases and were able to collect twenty-three from the literature—all of these found at autopsy. Zenker applied the term "pulsion diverticulum" to this type, and it has since been referred to as a "Zenker diverticulum."

Etiology.—Several writers give the lodgment of a foreign body as the one most important cause of the formation of these pouches. In our cases it is interesting to note that none of the patients gave a history of having swallowed a foreign body.

Zenker was the first to classify these lesions of the pharynx and esophagus. He divided them according to their method of formation into pulsion diverticula, due to pressure from within, and traction diverticula, due to a pull from without. In the pharynx one has to deal with the one produced by increased intrapharyngeal pressure. In the esophagus appear both the pressure and the traction varieties. Zenker's suggestions as to the etiology of these lesions stands unchallenged today.

---

[3] Zenker, F. A., and von Ziemssen, Hugo: Cyclopedia of the Practice of Medicine, New York, William Wood & Co. 8:1-214, 1878.

There is an area on the lower posterior pharyngeal wall where the fibers of the inferior constrictor muscle run in parallel lines in a thin layer from side to side. Above this point they are oblique and heavier and are interlaced. Below they are thickened and act as a constrictor of the upper end of the esophagus. This place seems not only anatomically disposed to the formation of diverticula but also the location which is most exposed to the causes likely to produce them. The canal at this point is at its narrowest; anteriorly is the unyielding cricoid cartilage. Here great pressure is brought to bear by the bolus of food forced downward, and, because of the anatomic weakness, the mucous membrane may be pushed through the fibers of the inferior constrictor. Jackson[4] believes that there is an incoordination in the neuromuscular mechanism which results in a failure of the lower part of the constrictor to open when the bolus presents itself at this point.

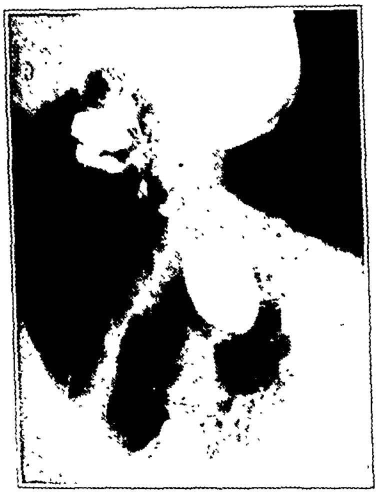

Fig. 1.—A large posterior pharyngeal pouch that has become intrathoracic, and two lateral pharyngeal pouches that are probably of branchial cleft origin.

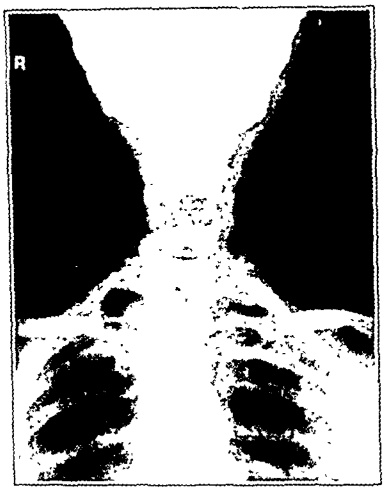

Fig. 2.—Asymmetry of the pyriform sinuses. The one on the right does not fill; possibly an etiologic factor in the production of a pulsion pouch.

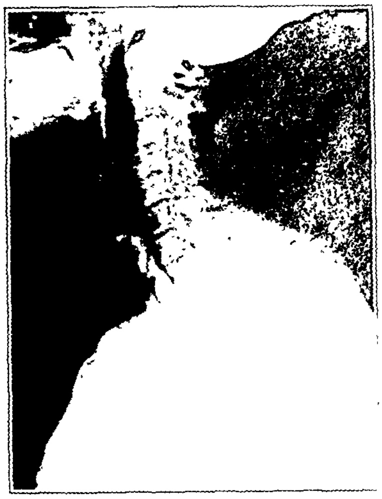

Fig. 3.—The symptoms produced by a pharyngeal pouch depend on its size, the small ones producing the sensations of slight dysphagia, a large one complete obstruction

Mosher[5] believes that there is an embryologic basis for the development of posterior pharyngeal pouches, pointing out the presence of a pouch in the early fetus, and calls to mind the fact that the pig has two pouches in this area. He also states that asymmetry of the thyroid cartilage, the pyriform sinuses and the mouth of the esophagus is a factor in the production of pouches.

Frequency.—Eighteen of our cases, or less than 2 per cent of 1,000 seeking relief from dysphagia, showed the presence of a Zenker pulsion diverticulum. The lesion is relatively uncommon, and less frequent than carcinoma, webs, fibrosis of the upper end of the esophagus, fibrosis of the lower end or "cardiospasm," cervical exostoses or paralysis of the muscles of deglutition.

Age.—The age of our patients varied from 40 to 83 years. The average age was 63 years, showing it to be a disease of later life. Lahey's[6] report of twenty-one cases with operation gives the average age of the patients as 67 years. This age incidence would seem sufficient to rule out any suggestion of congenital etiology.

Sex.—In our eighteen cases, fourteen were males and four females, a ratio which coincides with other reported series.

Symptoms.—The symptoms of a Zenker pulsion diverticulum depend on the size of the pouch. The patients under our observation gave a history of the duration of symptoms from six months to eight years, the average being three years, before they sought relief. There is no clinical picture which is absolutely characteristic of Zenker's pulsion diverticulum. The regurgitation of unchanged food is practically never absent but may occur with other lesions of the upper esophageal region. In the early stage, when the pouch is small there is a sensation as of a lump in the throat, which increases to a feeling of actual pressure as the sac enlarges. The presence of an excessive amount of saliva in the mouth and pharynx in the early stages has been mentioned by Jewett and Lichty[7] but has not been especially marked in our series of pouch cases, any more than was noticed with other lesions of the pharynx.

As the pouch enlarges, its opening becomes continuous with the lower pharynx. At the same time the opening of the esophagus becomes a mere slit on the anterior wall of the pouch, resulting in extreme dysphagia with the regurgitation of practically all food swallowed and an increasing sensation of pressure and suffocation. There may be gurgling noises in the throat, due to the mingling of swallowed air and food collected in the sac. A palpable swelling in the throat, more often on the left side, may sometimes be found after the sac has become quite large. A large diverticulum often presses on the laryngeal and pneumogastric nerve and causes hoarseness. A sense of suffocation and various cardiac symptoms are apt to occur as the sac enlarges into the thorax and presses on the vagus nerve.

Differential Diagnosis.—The differential diagnosis is important because of the other lesions in the esophagus occurring at this age, giving the identical symptoms. The average age for carcinoma in this region was 65 years. The symptoms are often very similar to those of diverticulum except, perhaps, that there is more emphasis on pain in the carcinomatous lesions than in the other conditions.

There are several nonmalignant lesions occurring in this region which may present very similar symptoms. Fibrosis of the upper end of the esophagus may cause varying degrees of stenosis. This degeneration is the result of transference of infection to the esophageal wall from pathologic changes in the cervical glands or adjacent structures in the neck. Mosher[8] has proved fibrosis of the lower end of the esophagus to be due to spreading of infection from extra-esophageal pathologic changes.

Webs of the mucous membrane, due to areas of ulceration, superficial infection or trauma, may produce a conflicting combination of symptoms suggestive of diverticulum. Not infrequently these webs are associated with spurs[9] arising from the inferior and superior border of the anterior aspect of the cervical vertebrae. These spurs push forward the pharyngeal or esophageal wall and produce marked dysphagia.

"Cardiospasm" may produce the same symptoms, even though the site of the pathologic condition is so much lower in the tract.

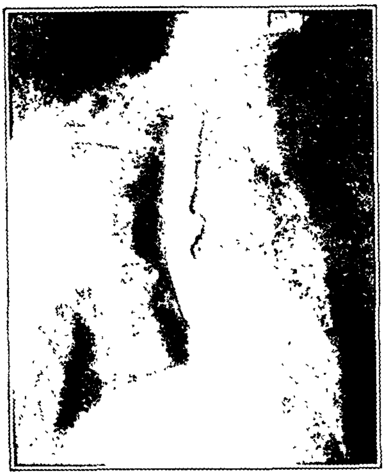

Fig 4.—The majority of esophageal pouches are of traction variety and are usually located on the anterior surface of the middle third and are caused by contraction of a healing peritracheal gland.

Partial paralysis of the lower pharyngeal muscles due to cerebral lesions or anterior poliomyelitis may produce the same symptoms that occur with a pouch. However, the sudden onset is of considerable value in differentiating the two lesions. Any one of the symptoms found with the pouch may be the first one complained of with paralysis. The same symptoms again may be produced by pressure from extrinsic causes, such as tumors arising from structures in the neck. These may present a confusing picture and a different clinical diagnosis.

Roentgen Diagnosis.—The one reliable means of correctly diagnosing diverticula is roentgen examination with barium paste. This at once establishes the presence and size of the sac and the degree of obstruction. The sharply circumscribed lower border and spilling over of barium from the upper level of the sac are absolutely characteristic and need not be confused with any of the other causes of dysphagia.

Hurst[10] reports an anterior pharyngeal pouch in a woman, aged 57, which showed on direct examination as a small slit immediately behind the arytenoid cartilage and in front of the esophagus, three-fourths inch in depth. Here the larynx prevents the pouch from enlarging anteriorly, causing it to obstruct the mouth of the esophagus when it fills. Occasionally, the pyriform sinuses are very deep and repeatedly catch and hold particles of food. This condition is quite frequently seen in roentgen examinations of the esophagus.

Moore[11] calls attention to artificially produced pouches in the depths of the pyriform sinuses, used by criminals for concealing coins.

Treatment.—There is no treatment of any value except surgical removal. Several operative procedures for the relief of Zenker's pulsion diverticulum have been described at different times.

The first recorded surgical operation was by Nicholadoni[12] in 1877. His procedure consisted of opening the sac and establishing a fistula. In 1884, Niehans[13] performed the first one-stage operation for complete removal of the sac. This patient died from hemorrhage on the twenty-fourth day. Wheeler[14] in 1886 performed the first successful operation for the removal of a pharyngeal diverticulum. Dugge[15] in 1893 found only twelve reported cases in the literature of successful removal. Since that time an increasing number of operative cases have been reported.

Gerard[16] in 1896 reported two cases in which operation had been successfully performed by invaginating the sac and suturing the esophageal walls. The sac was then allowed to atrophy or slough off. This same method was used by Waggett and Davis[17] in 1912, but ten months after the operation the sac recurred. This method was abandoned.

Bevan,[18] in 1917, reported a cure by a modification of Gerard's method, but the limitations of this operation have discouraged its use.

In 1910, Stetten[19] collected from the literature a total of forty-eight cases in which operation was performed by the direct excision method, with 18.7 per cent mortality, death in a majority of cases being due to mediastinitis.

In 1907, Goldmann[20] did the first two-stage operation in an attempt to eliminate the dangers of mediastinal infection. The first stage consisted of freeing the pouch from its bed, through an incision along the anterior border of the sternocleidomastoid muscle. The fundus of the pouch was attached to the upper border of the incision—the neck lightly constricted by a suture. After the mediastinal lymphatics were sealed off, about the tenth day, the second stage was done. The sac was excised at its neck and the opening suitably closed. Later, in 1909, he modified this method by tightening the suture about the neck in the first stage, causing the pouch to slough off. This invariably resulted in a fistula which remained open for weeks.

Hill,[21] in 1917, described his operation of "diverticulopexy," which was essentially the first stage of the Goldmann operation. The pouch was left with its fundus at a higher level than its neck and a suture lightly tied about its neck to prevent the entrance of food. He states that, in small and very large pouches, it would be well to include the second stage of the Goldmann operation.

Mosher[22] reported several cases in which he slit the common wall between the diverticulum and the esophagus, operating through the esophagoscope. He has since given up this method in favor of the two-stage operation.

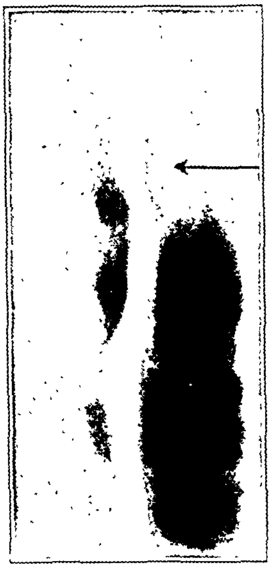

Fig. 5.—This calcified gland was not adherent to a fixed structure and in healing did not produce a pouch.

Imperatori[23] reported three cases in which he inverted the sac endoscopically and encircled it with a ligature. At the end of five or seven days the sac was removed by gentle traction. No infection followed the procedure. The size of the sac, as in the Gerard operation, limits the use of this method. Imperatori has since given up this method as unsafe.

Today, the two-stage operation of Goldmann is accepted as the operation of choice. It has undergone various modifications and refinements, such as Murphy's[24] operation, which omits the ligation at the neck.

Judd,[25] in 1918, sutured the neck of the sac to the skin, waited two weeks and excised the diverticulum. Following this he invaginated the stump into the esophagus. No anesthesia was used for the second stage.

Jackson[4] makes use of the esophagoscope to aid the surgeon in locating the sac. Lahey,[6] in 1930, reported twenty-one cases in which operation was performed by the two-stage method, with no mortality.

The successful removal of these pouches requires very nice judgment, familiarity with the structures encountered and painstaking perfection of the technic employed.

ESOPHAGEAL POUCHES

Esophageal pouches are entirely different from and should not be confused with those of the pharynx. According to autopsy records, esophageal pouches are more common than those of pharyngeal origin.

Zenker,[2] in 1877, was able to collect sixty cases of esophageal origin and only twenty-three of the pharyngeal type. Carman[26] found fourteen clinical cases reported between 1892 and 1919.

Pouches of the upper and middle third of the esophagus are not commonly diagnosed clinically, because they rarely produce symptoms of dysphagia. On the contrary, pouches in the lower third of the esophagus usually do produce symptoms.

In our series of esophageal diverticula, we found one in the upper third, four in the middle third and none in the lower third of the esophagus. The occurrence was 0.5 per cent of the causes of dysphagia.

These esophageal diverticula differ from the pharyngeal type in that they are evenly divided between the sexes and may occur at any age.

Rokitansky,[27] in 1840, is given the credit for first recognizing and describing the mode of formation of one type of esophageal diverticulum, to which he gave the name "traction diverticulum," in contradistinction to the pulsion diverticulum of the pharynx.

Traction diverticula owe their origin to the attachment to the esophagus of infected mediastinal glands or adhesions from infection of any of the surrounding esophageal structures, which contract on healing and exert a pull on that part of the esophagus to which they are attached.

Diseases of the tracheobronchial glands, especially those at the bifurcation of the trachea, make the anterior middle third of the esophagus the most common site for formation of these diverticula. They are usually cone shaped, with their base at their esophageal origin and the apex often at a higher level. Food does not accumulate with the diverticulum so formed; hence the infrequency of symptoms. Their walls may be composed of all the layers of the esophagus, or, if the muscle layer has been ulcerated through, it may consist only of the mucous membrane. A traction diverticulum may rupture into the bronchus or lung, as reported by Hawes.[28] Zenker considers this form very dangerous and apt to cause death by perforation into the trachea, bronchi, pleurae or great vessels.

Le Count[29] reports three cases of pouches found at autopsy occurring on the anterior esophageal wall between the aorta and the left bronchus, where the esophagus is not in contact with relatively firm structures like the aorta, bronchi or vertebrae. In these cases lymph glands were not found attached to the esophagus; the pouches were probably due to pressure from within.

In the same location another type of pouch is mentioned by Hill[30] and was first described by Lugard, who says that it is probably formed by the pouching of the left lateral wall of the esophagus over a connective tissue ligament running from the left bronchus to the dorsal vertebra. It is enlarged by the entrance and consequent accumulation of food into that part of the esophagus prolapsed over the ligament.

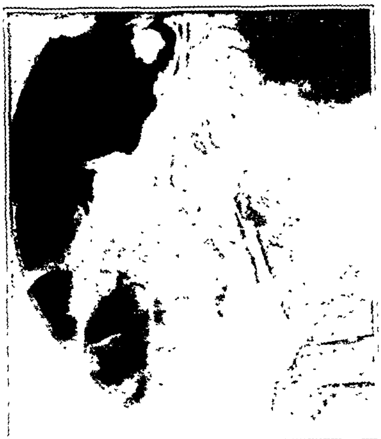

Fig. 6.—Multiple diverticula are uncommon and are usually the result of perforation of the esophagus by caustics.

Another group of pouches are those that occur in the lower third of the esophagus, the so-called epiphrenic or traction pulsion pouches, a name suggested in 1882 by Oekonomides.[31]

In a number of cases reported at autopsy, no evidence of the original traction agent could be found. This leads some observers to consider this type a pulsion type due to some defect in the esophageal musculature. They are sometimes found in cases of "cardiospasm." Vinson [32] considers congenital weakness of the esophageal wall a most important factor. Food lodging in these lower esophageal pouches may dilate them to a considerable size.

Barsony [33] reported two cases of duodenal ulcer in which, during fluoroscopic examination, in a certain phase of the esophageal function, diverticula appeared during the contraction. These, however, could not be observed in another phase. He called them functional esophageal diverticula due to a reflex relaxation from the duodenal ulcers.

Symptoms.—Esophageal pouches rarely produce symptoms and are found incidentally during life while searching for other pathologic changes. Carman [26] found fourteen clinical cases between 1892 and 1919, and added one from the Mayo Clinic. Smith,[34] in 1928, collected twenty-six cases more and added nine of his own, three of which were multiple. Only three of his own cases produced symptoms. The other six were diagnosed as a result of a careful routine esophageal examination in all gastro-intestinal examinations.

Portis [35] reported a diverticulum of the lower third in which symptoms of cardiac embarrassment were very marked and relieved only when the pouch was emptied by a stomach tube. Three of our patients complained of substernal distress and pain, sensation of obstruction in swallowing, but no emaciation or regurgitation of food, so frequently associated with the pharyngeal pouches.

Diagnosis.—Roentgen examination is the only means of differentiating between these and other esophageal lesions; the projection of barium beyond the normal lumen of the esophagus establishes the diagnosis. Great care must be taken to examine the patient in both planes.

Reitzenstein,[36] in 1898, was the first to discover this lesion by the use of bismuth emulsion and the roentgen ray. This was only one of eight clinical means he had for establishing a diagnosis.

Irrigation of the diverticulum affords relief when there is embarrassment due to filling of the large pouch. Feeding through a stomach tube may be necessary. Gastrostomy is sometimes resorted to.

Surgery of the esophagus is extremely difficult. According to Saint,[37] the chief reason for the late inception of surgery of the esophagus, its relatively slow progress and lack of attendant success can be summarized as follows:

1. The inaccessibility of the viscus. This applies particularly to the thoracic portion when its surgical approach is intimately bound up with previously developed operative procedures on the pleural cavity.
2. The absence of a serous coat in its cervical and thoracic parts.
3. A poor blood supply, interference with which often results in necrosis, tearing of sutures and extravasation of infective mucous secretion.
4. The danger of postoperative infection, cervical cellulitis, mediastinitis, pleurisy and empyema.
5. The probable danger of great shock resulting from interference with the vagi.
6. The presence of the diaphragm.

Relatively Small Percentage of Pouches as Compared with Other Diseases of the Esophagus and Pharynx

Condition	Per Cent
Carcinoma	45
Fibrosis of muscle (upper end)	16
Webs	13
"Cardiospasm"	10
Burns	6
Extrinsic causes	4
Paralysis	4
Pharyngeal pouch	2
Esophageal pouch	1

CONCLUSIONS

1. A careful examination of 1,000 cases of dysphagia showed pharyngeal pouches to be the cause of about 2 per cent and esophageal pouches less than 1 per cent.
2. Symptoms, which are not always characteristic, vary with the size.
3. A roentgen examination is the only means of differentiating between pharyngeal pouches and other lesions of the upper end of the esophagus.
4. Esophageal pouches are very commonly found at autopsy.
5. Surgical removal of pharyngeal pouches by the two-stage operation has proved to be the safest and most satisfactory procedure.
6. Surgical treatment of esophageal pouches presents the same difficulties encountered in all esophageal surgery.

483 Beacon Street.

ABSTRACT OF DISCUSSION

Louis H. Clerf, Philadelphia: Physicians are prone to consider the common form of pulsion diverticulum as originating at the upper end of the esophagus, knowing full well that the esophagus is not involved and that the opening of the pouch or diverticulum is promixal to the horizontal fibers or the cricopharyngeal portion of the inferior pharyngeal constrictor. There are no characteristic symptoms which can be considered as being absolutely diagnostic. Boyce's sign and a visualization of this sign described by me in Osler and McCrae's Modern Medicine have been demonstrated in cases of carcinoma of the cervical esophagus. In my experience the roentgen studies have not proved infallible. Three cases can be recalled in which a diagnosis of diverticulum was made by competent roentgenologists whereas the esophagoscopic diagnosis was cancer; in a fourth case the roentgen diagnosis of cancer was changed after esophagoscopy to diverticulum. Esophagoscopy certainly should be considered as a diagnostic procedure, particularly if there is a question in diagnosis. I agree with Dr. MacMillan that the only treatment worthy of consideration is surgical removal. At the Jefferson Medical College Hospital we have been employing a one stage closed operation for the past five or six years with excellent results in a large series of cases. Traction diverticula by reason of their large openings and the absence of a dependent pouch rarely produce symptoms and are commonly discovered during a routine functional esophageal study. I have observed three cases that produced moderate symptoms. One of these was located slightly above the hiatal level. The slight disturbance in swallowing referable to the epigastrium promptly cleared up following esophagoscopy. In the remaining two cases, posture seemed to aid.

Dr. Frank H. Lahey, Boston: In speaking of this condition, one should, I think, always qualify his experience with numbers and mortality. When one speaks of how to treat such a condition as this, one ought to say how many operations he has done by his method, how many patients have died and how many are well. That is basic. First of all, I have operated on thirty-one esophageal pulsion diverticula and none of the patients have died. I state this because I should like to do the one stage operation, but if one patient in a hundred died under the one stage plan of procedure, I should still feel justified in doing the two stage operation. It takes a little longer but it is an operation safe in principle and, therefore, I shall adhere to it up to the time that a considerable number of one stage operations have been done without mortality. There are three stages in pulsion esophageal diverticula, that with the simple projection, that with a definite sac and that with a long bulging sac in the mediastinum. In the first stage, that of bulging, there is merely a feeling of a foreign body sticking in the throat. In the second stage, that is the formation of a small sac, there is only regurgitation of food and mucus. In the third stage there is regurgitation of food and mucus and obstruction. I have learned from experience with these two stage operations that if one wishes to prevent complications during the first and second stages there must be complete dissection of the neck of the sac. The apex of the sac must be implanted in the wound higher than the neck of the sac, and in this way food does not pass into the sac, and the sac does not become dilated between the first and second stages. Furthermore, with high implantation following removal of the sac, at the second stage, there is little or no drainage and the wound closes usually at the end of from ten to twelve days. One should recall that, following the removal of the sac of an esophageal diverticulum, the factors which originally produced the condition are still present and it is necessary for some time afterward to do dilation of the esophagus with bougies. Because of the irregularity of the esophagus as the result of the operative scar, it is wise to ask these patients to swallow a string as a guide to the bougie that is to be passed.

BENIGN TUMORS OF THE STOMACH

WITH REPORT OF CASES *

BRUCE C. LOCKWOOD, M.D.
DETROIT

Because of their relatively rare incidence, varied morphology, pathology, symptomatology, and roentgen evidence, benign gastric tumors give rise to great clinical interest. That they are more frequent than is generally considered is evidenced by a comparison of the number of benign with the number of malignant gastric tumors examined in the pathologic laboratory which were either removed at operation or discovered at autopsy.

At Harper Hospital during the past seven years there have been 12 benign gastric tumors examined in the pathologic laboratory, during which period there have been 266 cases of malignant gastric tumors in the hospital, an incidence of about 4.5 per cent. Hillstrom [1] found that in the department of pathology of the University of Minnesota, about 5 per cent of all the tumors discovered at autopsy or removed at operation were benign. There have been nearly a thousand cases reported.

Pathologically, the benign tumors which have been reported include fibromas, fibromyomas, myomas, adenomas, angiomas, lipomas, myxomas and cysts.

Morphologically, these benign tumors may vary in size from that of a pea to that of a grapefruit, but the majority have been less than 2 or 3 cm. in diameter. They may be single or multiple; the single growths predominate in case reports, but the fibromas and adenomas are more often multiple. Their site of preference has been the middle third of the stomach, but they are reported as occurring anywhere in the tract from the region of the lower esophagus to the duodenum. They may be entirely intramural, project into the lumen of the stomach in sessile or pedunculated form, or, less frequently, project outside the stomach on a pedicle.

Polypoid growths inside the stomach, frequently mentioned as mucous polyps or gastric polyps, are more often adenomas, although they may occur with other histologic patterns or be mixed tumors of connective tissue and glandular origin. When these small growths occur in large numbers, the condition is known as gastric or multiple polyposis. Numerous cases have been reported, although the condition is extremely rare. In Balfour's [2] experience it was found only once in 69,000 abdominal operations. When these single polypoid growths are large enough and occur near the pylorus, they are described as ball valve tumors.

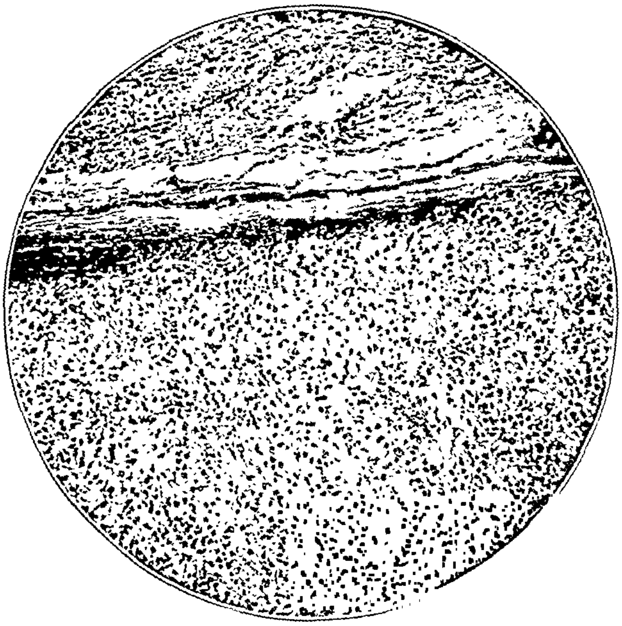

Fig. 1 (case 1).—Section of nonmalignant neuroblastoma removed from posterior wall of the stomach

Eusterman and Senty [3] found twenty-seven benign gastric tumors occurring at the Mayo Clinic between the years 1907 and 1921: ten myomas, five fibromas, four angiomas, two dermoid cysts, one gastric polyposis, two adenomas and three polyps.

Eliason and Wright,[4] in 1925, reported fifty cases found at operation or autopsy: sixteen papillomas, sixteen polyps, six fibromas, five adenomas, four myomas, one cyst and one lipoma. Moore,[5] in 1924, reported twenty-three cases diagnosed roentgenologically and proved at operation. In 1927 he [6] reported eighteen additional cases observed during the intervening three years. Holmes,[7] in 1927, had seen seven proved cases occurring in about 30,000 examinations

during the previous fifteen years. Mason and Dwyer[8] found only three cases of benign tumors in 4,000 roentgenologic and clinical examinations. Rigler[9] found eleven cases of benign growth to seventy-four cases of carcinoma in an unstated number of gastro-intestinal examinations during a two year period. A more complete discussion of the literature has been given by the authors mentioned.

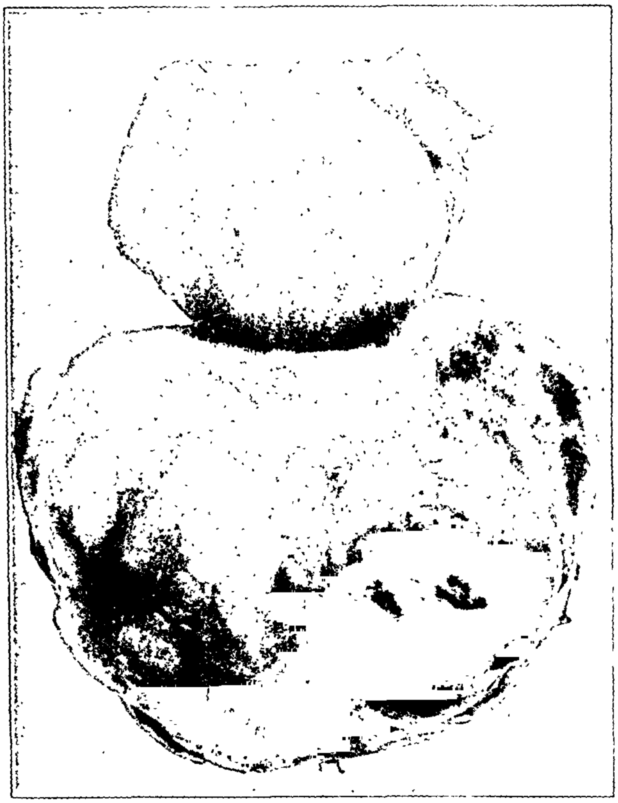

Fig. 2 (case 2).—Fibroid masses removed from lesser omentum

In this series of twelve cases there were five fibromas, three adenomas, two pancreatic rests, one polyp and one neuroblastoma. The literature does not reveal a gastric neuroblastoma previously reported.

SYMPTOMS AND LABORATORY OBSERVATIONS

The symptoms are determined by the size, nature and position of the growth. The smaller growths may exist symptomless, provided they are not ulcerated and are not near the sphincter; such tumors have been discovered at autopsy.

Larger tumors, intramural or pedunculated, have usually produced enough disturbance of gastric function from pressure or traction to cause variable, intermittent, long standing symptoms of indigestion, such as distress or pain after meals, heartburn and nausea, not characteristic of any one specific condition. Tumors, sessile or pedunculated, situated near the pylorus, may produce an intermittent ball valve pyloric obstruction, with attacks of severe pain, nausea, vomiting and often bleeding, probably due to torsion of the pedicle and strangulation. Complete pyloric obstruction may take place with gastric dilatation, food retention and visible peristalsis. These obstructions have usually been temporary, as the tumor often falls back into the stomach with relief of symptoms, until the next recurrence.

Intermittent bleeding has also often been seen from polyps situated away from the pylorus, probably because of their excessive vascularity, especially the angiomas. Superficial ulceration also may take place.

Malignant degeneration not infrequently occurs, especially in the adenomatous types, producing, together with a restricted diet, a gradual loss of weight and advancing anemia.

The laboratory observations are not characteristic. Achlorhydria is frequent, especially in the cases of hypertrophied gastric mucosa and polyposis. There is an increase in mucus, occasionally blood, and in a few cases a polypus has been caught in the eyelet of the tube, recovered, and examined microscopically. In other cases a hyperchlorhydria with variable degrees of delayed evacuation has been found, simulating pyloric ulcer. Secondary anemia is common.

Physical signs relate only to palpating the tumor mass, which depends on the size of the tumor and the thickness of the abdominal wall. This is more likely to be accomplished under fluoroscopic guidance.

ROENTGENOLOGIC EVIDENCE

Roentgenologic examination is by far the most valuable method in diagnosis. Of greatest importance in finding any of the smaller lesions of the stomach is the careful routine and unhurried fluoroscopic examination, with careful approximation of the stomach walls and determination of organ mobility by manual pressure. Observations should be made from different angles in both the upright and the prone positions, with the stomach containing only a few swallows of barium. Overfilling of the stomach may obliterate a view of the defect.

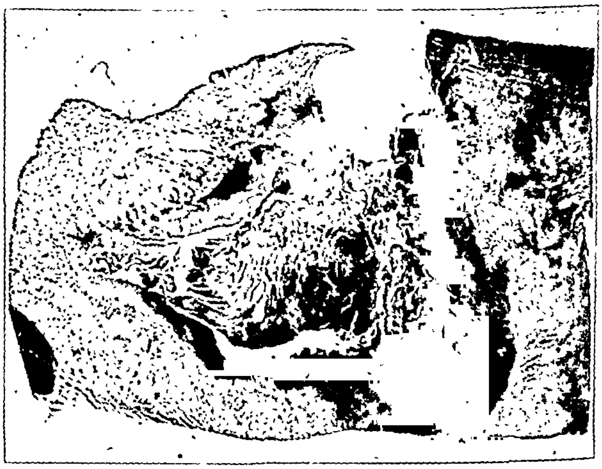

Fig. 3 (case 2).—Section of gastric myoma showing round cell infiltration, necrosis and ulceration.

The characteristic sign of a mural, sessile or internal pedunculated growth is the round or oval sharply contoured filling defect. Since most of these tumors arise from the mucosa or submucosa, they are central rather than marginal and can be shifted within the stomach in varying degrees by palpation. They appear as rounded translucences, much like a foreign body in the lumen of the stomach. As the gastric musculature usually remains unaffected, the peristalsis is uninterrupted and

9. Rigler, L. G.: Am. J. Surg. **8**: 144 (Jan.) 1930.

the wall remains pliant. Except in cases of multiple polyposis, the rugae have a normal appearance; they are not in star shaped, convergent folds as in ulcer or scar, and are not obliterated as in cancer. Absence of the spasm and diminution in the size of the stomach, usually seen in ulcer or cancer, are other characteristics of benign growths. A mass may or may not be felt. Multiple growths are strongly indicative of a benign character.

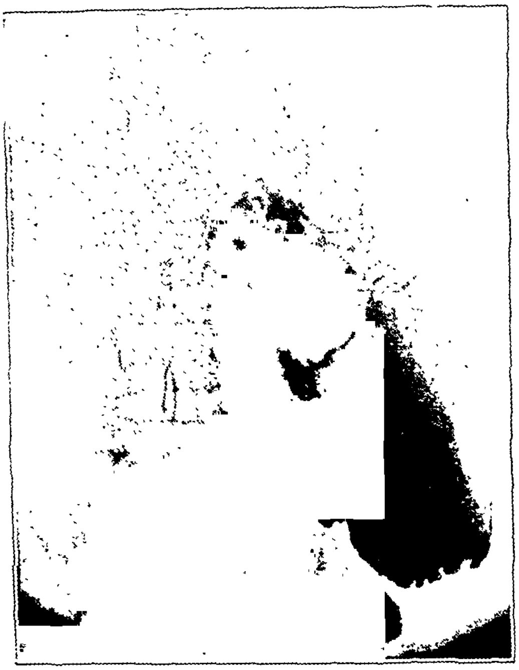

Fig. 4 (case 3).—Marginal ulcer with polyp.

In gastric polyposis the numerous small rounded defects or translucences are described as giving a characteristic picture, resembling a sponge or finger marks.

A small growth in the antrum may give only a vague filling defect and a six hour residue, suggesting a pyloric ulcer or cancer. A polypoid growth prolapsing into the duodenum gives a central translucence which may be fairly diagnostic.

TREATMENT

Treatment, aside from the palliative, is entirely surgical, and should be carried out as soon as possible, on account of the not uncommon occurrence of malignant degeneration, especially of the adenomatous type of tumor. Friedenwald and Finney[10] and others have reported such cases. The end-results from surgical excision are reported as excellent.

In cases of multiple polyposis, gastric resection is indicated, provided the disease is causing enough trouble to warrant such operative risk.

REPORT OF CASES

The following case reports represent examples of the different morphologic types of tumor with their different manifestations:

Case 1.—F. D., a white man, aged 42, who consulted me, July 8, 1929, had an irrelevant past history for a painless jaundice lasting two weeks in 1914. The present complaints began in 1927, since which time he had had periods, lasting from one to two months and occurring two or three times a year, of a burning epigastric pain, coming on from half an hour to three hours after meals and radiating upward under the sternum and at times to the right upper quadrant of the abdomen. The pain was relieved often by soda and by induced vomiting. He had had no nausea and had never vomited spontaneously. On four or five occasions he had had attacks of a more severe and diffuse epigastric pain coming on at about 3 a. m. and lasting from two to three hours, requiring morphine for relief. He had not had any hemorrhages. He had lost about 25 pounds (11 Kg.). The bowels were normal. Physical examination was negative except that there was moderate tenderness in the epigastrium and in the right upper abdominal region. Laboratory examination showed: urine, normal; blood count, normal except for slight secondary anemia; blood Kahn reaction, negative. Gastric analysis showed an achlorhydria. On fluoroscopic examination the chest was found to be normal. Ingestion of the barium meal showed the esophagus normal. The stomach was of the intermediate type with active two cycle peristalsis. With the stomach containing from 1 to 2 ounces of the barium, the rugae were found to be of normal size and direction. On the posterior wall in the middle third of the stomach was a slightly tender filling defect about 3 to 4 cm. in diameter, with a smooth border, easily palpated and movable about 2 or 3 cm. Further filling of the stomach with the opaque mixture obliterated a view of the tumor. The duodenum was normal, but there was considerable tenderness in the gallbladder region; normal motility was present at five hours. The remainder of the tract was normal.

Oral administration of the dye did not show any filling of the gallbladder at the fifteenth, eighteenth, or twenty-first hour. No stones were demonstrated.

A diagnosis of a nonmalignant intramural tumor of the posterior wall of the stomach, with probable gallbladder disease, was made.

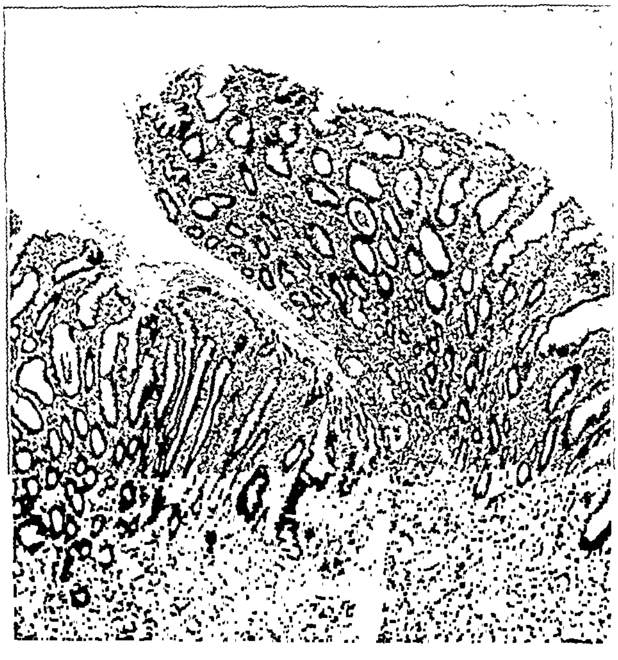

Fig. 5 (case 3).—Section of nonmalignant papillomatous polyp.

Subsequent observation during attacks of pain showed on one occasion much gallbladder tenderness and some spasm of the right upper abdomen. In other attacks this was not apparent. In Harper Hospital, preliminary to operation, the roentgen observations were confirmed by Drs. Evans and Reynolds although in the meantime in another city roentgen studies were reported as entirely negative.

The patient was operated on, October 3, by Dr. Max Ballin. A round tumor of firm consistency, about 3 cm. in diameter, was excised from the posterior wall of the stomach. It arose in the submucosa and was slightly sessile. A cholecystitis was also found, with two stones lodged in the cystic duct. A cholecystectomy was done. The pathologic condition of the tumor was reported by Dr. A. S. Warthin to be that of a nonmalignant neuroblastoma (fig. 1).

---

[10] Friedenwald, J., and Finney, J. M. T.: Am. J. M. Sc. **154**: 683 (Nov.) 1917.

Case 2.—Mrs E. B., a white married woman, aged 50, who was referred in March, 1927, gave a past history which was irrelevant except that she had had a fibroid uterus removed in 1923. She had never been pregnant. The chief complaint was that intermittently during the past year she had been able to feel a lump in the upper portion of the abdomen. No pain and no gastric disturbance had been noted, but there had been some soreness in the lump during the spells when it was palpable. There was also some dyspnea and palpitation on exertion. The patient was well nourished. The pulse was 100 and the blood pressure was 190 systolic and 115 diastolic. A moderate cystadenoma of the thyroid was noted and the heart was moderately enlarged, with an occasional premature systole. In the epigastrium was palpated a smooth, hard, round, slightly tender mass about the size of a lemon, freely movable about 4 inches (10 cm.) in each direction, which could almost be made to disappear under the margin of the left ribs.

Laboratory examination showed that the urine was normal; achlorhydria was noted in a single test meal; the stool was normal; there was moderate secondary anemia; the Kahn reaction was negative. The basal metabolism was plus 11.

Roentgen examination showed the chest normal except for some cardiac hypertrophy. The esophagus was normal. The stomach was of the intermediate type, showing two cycle, uninterrupted peristalsis. There was no evidence of ulcer or growths. The palpable mass appeared to be outside the stomach, resting along the lesser curvature, and produced a broad shallow pressure defect. On manual movement of the mass upward, the stomach also seemed to be drawn upward but not to the extent that the mass could be moved. Manual movement of the stomach also seemed to move the mass. The stomach was empty at five hours, and the rest of the tract was normal. A diagnosis of a tumor or cyst of the lesser omentum or lesser peritoneal cavity was made and operation was advised. This, however, was postponed by the patient for two and one-half years, or until the tumor had grown to the size of a grapefruit and there were several attacks of rather severe pain. During this time I lost contact with the patient until the day of operation. She was operated on in October, 1929, by Dr. Angus McLean. A large round fibroid mass about 15 cm. in diameter was found adherent in the lesser omentum and attached to the lesser curvature of the stomach by a short broad pedicle (fig. 2). Attached to the side of the mass also by a short broad pedicle was another tumor of like consistency but about half as large. In the stomach at the site of the attachment of the tumor was a gastric ulcer. The tumor and ulcer were excised, and the patient has remained well.

Pathologic examination of the tumor by Dr. P. F. Morse showed that the specimen consisted of a vascular myoma of the gastric wall, with recent round cell infiltration, and a large area of necrosis, with ulceration (fig. 3).

Case 3.—T. F., a white man, aged 32, single, had had a gastro-enterostomy for duodenal ulcer in 1919, after which he remained well for one year. In 1920 there was a return of symptoms, and examination and operation disclosed a marked enlargement of the jejunum, due to an obstruction and adhesions distal to the stoma. Freeing of the adhesions and obstruction gave relief for another year. In 1922 a diagnosis of marginal ulcer was made and the patient was operated on again in 1923, when the gastro-entero-anastomosis was removed, a very large ulcer excised, the lower half of the stomach resected and a posterior Polya anastomosis performed. He remained well for three months, when there was a return of the symptoms, and roentgen examination by Drs. Evans and Reynolds disclosed a new marginal ulcer, with the probability of a polyp (fig. 4). In 1927 he was operated on again, and the ulcer was excised together with a polyp about 2 cm. long, originating at its edge.

Dr. P. F. Morse reported that the tumor consisted of redundant gastric mucosa with areas of buried glands, and infolding of a nonmalignant papillomatous polyp (fig. 5).

CONCLUSIONS

The relative incidence of benign to malignant growths in the stomach is about 1 to 20, as shown by the records from both operating and autopsy rooms.

The percentage of diagnosed cases of benign tumors would be increased by more frequent and more careful fluoroscopic study. The roentgen observations are reasonably characteristic. In order to demonstrate the smaller lesions, the stomach must contain only small quantities of the contrast mixture, the walls must be approximated by manual pressure, and the patient must be examined in both the upright and the prone position.

The symptoms are not typical; they vary with the site, size and character of the lesion, and may simulate other forms of indigestion.

Because of the tendency of these slowly growing benign tumors to become malignant, their recognition is important and their surgical removal indicated.

10 Witherell Street.

ABSTRACT OF DISCUSSION

Dr. George B. Eusterman, Rochester, Minn.: In Dr. Lockwood's opinion, the frequency of benign tumors of the stomach amounts to about 5 per cent. This is considerably higher than my incidence of 1.3 per cent, in a paper which I published in 1922. Undoubtedly the incidence is greater than in the statistics which I quoted, owing to the rapid accumulation of other convincing case reports in the literature in the last decade. Up to the present I have had some sixty-five surgically verified cases of my own. It is also quite likely that a certain percentage of lesions regarded as inoperable carcinomas of the stomach because of their high situation in the organ are benign. This has been proved by the fact that it was only on the insistence of the patients, demanding exploration in spite of the unfavorable site of the growth, that the true nature of the lesion was determined, it being benign and not malignant. From the standpoint of the pathology of these lesions I have nothing more to say, except that they are of a diverse nature, as emphasized by the author and by other writers, and that the only complication such tumors do not have that ulcers do is perforation, acute or chronic. They may all obstruct or bleed, or undergo carcinomatous transformation, and, in addition, may intussuscept. Some of the most dramatic and painful complications that I have seen were the result of intussusception of such tumors situated in or near the pylorus. The roentgenologic aspects of these lesions have been well summarized by the author and I might say that he has included practically all the criteria that Moore and his associates laid down several years ago and which have been confirmed by all other roentgenologists. From the symptomatic standpoint one must remember that these tumors are frequently symptomless, especially those that are small and do not involve the orifices. Some of these tumors are quite large, without producing symptoms, although evidence of anemia or hemorrhage may be present. Moreover, they do not involve the curvatures as ulcers and cancers do, but have a predisposition to the anterior and posterior walls. Apparently not all these tumors have characteristic roentgen changes. Formerly, the majority of benign tumors were considered to be carcinomatous, but nowadays they are often called benign when at operation they really turn out to be carcinomatous. Finally, I wish to stress the high incidence of anemia and the infrequency of pyloric obstruction and palpable mass. Some of these lesions are associated with an anemia of severe grade, indistinguishable from pernicious anemia, and usually with an absolute achlorhydria. These cases are being followed with interest since removal of the lesions. It is also important to exclude tumors, sometimes benign, of the upper digestive and intestinal tracts in all cases of unexplainable anemia, especially in the presence of gross or occult bleeding from the digestive tube.

Dr. Frank Smithies, Chicago: In your classification of benign tumors do you exclude gummas?

Dr. Eusterman: I exclude gummas. We consider them granulomas and not growths, in the strict sense.

Dr. Maurice Feldman, Baltimore: Diverticula of the duodenum are not an uncommon observation. The condition is reported with greater frequency because of better and more thorough roentgen studies made in the routine gastro-intestinal examination. The diagnosis of duodenal diverticula in most instances is accidental, the roentgen ray offering the only preoperative means of diagnosis. Not infrequently, however, the pouches may be overlooked or overshadowed and may remain unrecognized or at times even misinterpreted. I should like to emphasize the importance of the fluoroscopic method of examination as a method of choice in the detection of diverticula involving the duodenum and the importance of observing the duodenum with meticulous care, with the palpating hand. It is also necessary to take roentgenograms in various positions in order to recognize some diverticula. In my experience with diverticula, I find that manipulation and pressure over the duodenum in the roentgen study is an important procedure which cannot be too strongly stressed in the diagnosis.

DIVERTICULA AND DIVERTICULITIS *

JEROME M. LYNCH, M.D.
NEW YORK

Diverticula may occur anywhere in the intestinal tract, and in many instances there is an embryologic excuse for their existence. They occur from the appendix to the anus but more frequently in the sigmoid than in any other part of the alimentary canal.

The bowel is developed from a diverticulum and from it, as diverticula, arise the liver and pancreas and the cecum with its degenerate end, the appendix. In regions where diverticula are a normal developmental necessity, sporadic secondary diverticula may occur. In other instances they may be merely structural imperfections of early fetal life, as in the case of the outgrowths of intestinal epithelium perforating the muscular coat, which occur about the third month and which may, later on, be responsible for diverticula (Lewis and Thyng).

Although this subject has been sporadically mentioned in the literature for some 230 years and the possibility of secondary pathologic trouble has been recognized, it is only within the last decade or two that it has received serious attention. Telling has said that "until a morbid condition is described in all the ordinary student textbooks of medicine and surgery it cannot be said to have obtained complete recognition." The truth of this is evident.

The disease was mentioned by Cruveilhier in 1849 and by Virchow in 1853, both commenting on its frequency. For the next decade or two there was quite a revival of interest in the subject, Rokitansky being responsible for the classification of diverticula into "true" and "false." In 1873, Mr. J. W. Hulke reported a case of diverticulum of the small intestine which had become adherent to the rectum and eventually opened into it. Sidney Jones and Mr. Hawkins in the same year reported cases of "false" diverticula of the sigmoid, ending in a vesicosigmoidal fistula. Pratt's case was an instance in which a loop of the small intestine had become adherent to the wall of the pelvic colon, resulting in intestinal obstruction.

However, in this period all credit must be given to Sir Charles Ball for his most exhaustive and enlightening description of the disease and all its possibilities for trouble. This article can be found in his textbook on "Diseases of the Rectum and Colon" published in 1887.

Strange as it may seem, in view of the active interest in this subject between the decades of 1870, 1880 and 1890, it seems to have escaped the notice of the general medical profession. The period of the renaissance may be dated from 1898, when Graser's paper appeared. This was followed by studies by Fischer, Beer and Moynihan, and an excellent contribution in 1907 by Mayo and Wilson. In 1908, Telling published a comprehensive review of the whole subject. From then on up to the present, many papers have appeared. Those chiefly of interest were by W. J. Mayo, McGrath, Lejars and Menetrier, Lockhart-Mummery, Judd, Masson, Spriggs and Marxer. To Case belongs the credit for having first suggested "diverticulosis" as a title for the noninflammatory mucosal herniations.

Almost all phases of the disease have been exhaustively studied, and some rare secondary and far-reaching complications have been mentioned, which should emphasize the necessity of always being on the qui vive for an early diagnosis, with the hope of avoiding these complications and fatalities.

Diverticula may be divided into complete, which involve all the coats of the intestine, and incomplete, which involve only the mucosa and peritoneum. I think that the classification of diverticula as true and false, suggested by Rokitansky, is much better than division into congenital and acquired, because to my mind the evidence, so far, in favor of the acquired theory is not convincing. All the causes so far assigned do not satisfactorily explain diverticulosis. I believe that diverticula, like hernias, have the same underlying cause; like cancer they occur at all ages but are most manifest after the age of 35; they occur more frequently in males than in females, are much more frequent than is at present appreciated, and are always associated with symptoms; but, as in hernia and a good many other diseases, the symptoms are not so obvious as to suggest their origin. In other words, there are so many other ways to account for the symptoms accompanying diverticulosis that they are usually assigned to some simpler pathologic condition.

All people with diverticulosis have symptoms, but the symptoms are overlooked and are considered as being due to dietary indiscretions and the like. There is always dull aching pain. The average practitioner unfamiliar with diverticulosis would not associate with that disease a dull aching pain accompanied by occasional attacks of diarrhea, alternating with constipation and gaseous distention. When these lesions occur on the right side, in the appendix, cecum or ascending colon, they are much more likely to receive serious attention and be discovered than if they are on the opposite side. This is obvious when one considers that most of the acute abdominal conditions are confined to the right abdominal cavity and that most of the developmental abnormalities are on the right side. Naturally, when a patient complains of pain or discomfort there, he stands a good chance of being roentgenographed and thoroughly overhauled, but not so when the lesion is on the other side. Yet, as a matter of fact, most of the acute cases of diverticulitis occur on the left side, particularly in that most variable portion of the alimentary canal, the sigmoid.

Diverticulitis may occur at any point where a diverticulum has formed, but the most frequent site is the sigmoid. The sigmoid is a loose, movable organ and may be up in the abdomen one moment and in the pelvis

---

* Read before the Section on Gastro-Enterology and Proctology at the Eighty-Second Annual Session of the American Medical Association, Philadelphia, June 12, 1931.

the next. It is subject to twists and volvulus and variation in position. This seems to me the probable reason why inflammation occurs most often in the sigmoid. The sigmoid usually contains hard fecal matter, and its variations of position cause it to be more liable to injury than are any of the other parts of the colon.

The symptoms of diverticulitis vary with the pathologic condition. The pathology is practically the same as in appendicitis. If there is an acute condition, all the symptoms are present that one sees with acute appendicitis; viz., pain, rigidity, rise of temperature and vomiting. Mummery's suggestion to divide these cases, from a clinical standpoint, into those in which there is a tumor formation and those in which there is an acute abscess is excellent, because in the one instance one is dealing with an acute, active, surgical condition, while in the other the condition is a chronic one that does not require immediate active surgical intervention.

The sequence of events and complications of a diverticulitis depend on the pathologic process. There may be a thinning of the mucosa, with the passage of toxins into the bowel, local peritonitis and adhesions. The diverticulum may become strangulated and slough off into the peritoneal cavity. An abscess may form which can wall itself off or perforate, presenting the same symptoms as in the perforation of any abscess into the bowel or peritoneal cavity. There may be a hyperplastic inflammation as in tuberculosis, and this is the most frequent. Adhesions may form to any organ in the abdominal cavity, frequently to the bladder with perforation into the bladder. The symptoms arising from any of these complications depend on the nature and site of the pathologic process.

There is no medical treatment for diverticulosis any more than there is any medical treatment that will abort appendicitis. In my opinion, all people with diverticulosis would be better off with an appendicostomy; diverticulitis would be less likely to develop. When an acute pathologic process is present, the best procedure is to make a stoma cephalad to the site of pathologic change and always at a sufficient distance so as not to interfere with subsequent surgical intervention. When there is a fistulous opening into the bladder, it is better to allow the colostomy or stoma to remain open for a long time, in the hope that, if the current is sidetracked and the source of infection is eradicated, the opening into the bladder will close up. It is never safe to try to close the opening until all the inflammation has subsided. If it does not close of its own accord, an attempt may be made to close it afterward.

I have done five resections of the sigmoid for the hyperplastic type of diverticulitis. Four patients recovered, and the other died of peritonitis. If I had known as much then as I do now, I would not have attempted the resection until after the patient had been colostomized for some time.

The diagnosis of diverticulitis is sometimes a matter of great concern, for there are other conditions which closely simulate it. Because of the mobility of the lower sigmoid, the symptoms may be entirely right-sided and suggest appendicitis, a justifiable and quite natural error. If the diverticulum involved is located in other parts of the colon, a relatively infrequent occurrence, accurate diagnosis may be impossible. Occasionally, acute intestinal obstruction occurs, supervening on a chronic hyperplastic diverticulitis or kinking of the small intestine by adhesions.

In the realm of differential diagnosis I would mention carcinoma of the rectosigmoid, malignant vesicocolic fistula, gynecologic conditions in the pelvis, sigmoiditis, hyperplastic tuberculosis and syphilis.

Carcinoma of the rectosigmoid may be ruled out by careful sigmoidoscopic and roentgenologic investigation, but sometimes the diagnosis cannot be made until the specimen has been sectioned by the pathologist. In this connection it may be stated that a number of cases of carcinoma, secondary to diverticulitis, have been reported. I have had two cases. Malignant vesicocolic fistula may be ruled out by cystoscopic study. The absence of blood in the stools cannot be relied on in making a differential diagnosis, because I have seen a number of cases of diverticulitis not alone with blood in the stools but with severe hemorrhages. Theoretically, it should be easy to distinguish between diverticulosis and carcinoma of the sigmoid, as a diverticulosis has a much longer history, with frequent attacks of acute exacerbations and remissions, whereas in carcinoma there is practically no discomfort until the tumor is well established or until it involves the lumen of the bowel. There is apt to be much more blood and mucus in the stool of a patient suffering from carcinoma, but as a matter of fact many cases of carcinoma of the sigmoid closely resemble diverticulosis in that the entire wall of the bowel is apt to be involved. Theoretically, it should be confined to the mucosa before it is discoverable, but this is not always so.

Again, carcinoma of the sigmoid not infrequently becomes adherent to the side of the pelvis, and then a perisigmoiditis with abscess formation occurs. This will sometimes give the appearance of diverticulosis. On account of ulceration, carcinoma located just before the peritoneal reflection is not infrequently associated with abscess. I have more than once, in dissecting, opened up an abscess; and, as was to be expected, there was a history of fever and pain, together with bladder symptoms, previous to operation. The diagnosis in these cases, therefore, is not by any means as simple as one would suppose.

It has been suggested by some that loss of weight in carcinoma should serve as a distinguishing feature in comparison with diverticulosis, but as a matter of experience I have found very few cases of carcinoma, except in the advanced stages, in which there was loss of weight. In St. Bartholomew's Hospital there was one instance in which a woman with a very advanced carcinoma gained weight for many months, when she was in an inoperable condition. Therefore, loss of weight cannot be depended on to differentiate carcinoma from diverticulosis.

Pelvic conditions involving the general organs are not infrequently due to diverticulitis of the sigmoid, as shown by Poulain. Giffin describes pelvic tumors in four women suffering from diverticula without any coexisting bowel symptoms. Sigmoiditis occurs at an earlier age than diverticulitis, usually recedes spontaneously, and, pathologically, is apt to involve the mucosa. Hyperplastic tuberculosis almost invariably involves the cecum, and some tangible evidence of tuberculous infection is usually available. Syphilis should always be thought of and ruled out.

The usefulness of the x-rays in diagnosis has been occasionally limited by the physical impediments to the entrance of the barium mixture into the diverticular sac, but in the majority of instances roentgen examination is invaluable.

It is doubtful whether medical treatment can prevent diverticulitis. It seems to me that appendicostomy would prevent diverticulitis. The treatment of diverticulitis is obviously surgical.

REPORT OF CASES

CASE 1.—A woman, over 50, referred by Dr. Torrens in 1926, gave a history of occasional severe attacks of pain in the left lower quadrant, over a period of many years. Five days before I saw her she had severe colicky pains with constipation and fever, continuing for two or three days, when she began to vomit. She had been vomiting for two days previous to my seeing her. She was brought into the hospital with a distended and tympanitic abdomen, a rapid pulse and a temperature of about 101. She was immediately prepared and sent to the operating room, with a diagnosis of intestinal obstruction of some form. When the abdomen was opened by a left rectus incision, a long sigmoid, studded with diverticula, came into view. On further exploration it was found that the inflamed diverticulum had become adherent to a loop of small bowel, which was incarcerated in a femoral hernia. An ileostomy was performed, but the patient did not recover.

CASE 2.—T. S. R., a man, aged 59, tall, very thin and delicate looking, complained of long standing definite discomfort in the left iliac fossa. The bowels had always been regular. He had never passed blood or mucus. Two weeks previous to the examination he had had abdominal cramps, low down on the left side. Four days previous to examination he had such severe pain that he had to go to bed. The pain was so severe that he kept an ice bag over the lower left portion of the abdomen, over the sigmoid. The temperature was 100. The sigmoid loop with the inflamed diverticulum had prolapsed into the culdesac and was in close proximity to the bladder. There was danger of rupture of the diverticulum into the bladder, resulting in a fistula. Colostomy was advised but was not accepted.

CASE 3.—A patient who complained of a constant pain in the region of the appendix with tenderness over the cecum, and constipation, was operated on, with a preoperative diagnosis of chronic appendicitis. The presence of diverticula was discovered at operation. The appendix was removed, and the histologic examination showed a catarrhal inflammation. I did not feel justified in resecting the cecum because, even though the diverticula were present, none of them were inflamed. The patient was improved by the operation but continued to have a dull ache in the region of the cecum.

CASE 4.—Mrs. O. S., aged 55, had had an operation on the uterus some years before, and a nervous breakdown in 1913, one year prior to presentation, but was otherwise healthy. She complained of stomach trouble, gas, and pains in the epigastric region. Vomiting occasionally gave relief from pain. The bowels were constipated, requiring cathartics for any bowel movements. One year ago the patient passed a little blood and mucus. She had been losing weight for seven months (20 pounds, or 9 Kg.). For two months previous to examination she had an imperative desire to move the bowels, the first thing in the morning, and passed only a little blood and mucus, which gave relief. There was always a feeling of unfinished stool. She had an uncomfortable feeling in the abdomen and constant backache for two years. Physical examination revealed that the heart, lungs and chest were normal. A double hernia was present, and there was tenderness over the gall-bladder, appendix and sigmoid. A diagnosis of diverticulitis of the sigmoid and colon was made.

CASE 5.—Mrs. W. P. W., complained of pain in the left side of the abdomen and across the abdomen. The bowels were never constipated. Roentgen examination, in 1921, showed the sigmoid deeply haustrated but not unduly long. On each side of the sigmoid shadow there was a series connected with it by a narrow isthmus. The descending colon was not filled; the transverse colon had rather poor tone. There was a filling defect due to gas distal to the hepatic flexure. A diagnosis of diverticulitis of the sigmoid was made. Operation was not performed. The patient was in St. Bartholomew's Hospital for eleven days. Treatment consisted of diet and enemas. The patient recovered and returned home. She had regular bowel movement daily and no recurrence of pain. No discomfort was felt after eating.

CASE 6.—F. M., aged 38, complained of pain in the left iliac region, a slight fever and severe abdominal cramps, but no chills were present. Examination revealed tenderness and a mass over the left iliac region. Operation was performed in 1917 at the Polyclinic Hospital, with a left rectus incision. The sigmoid was found to be adherent in the iliac fossa and covered with omentum. Numerous diverticula were seen over the area of the lower sigmoid. There was an abscess cavity which was opened into on the lateral outside wall of the lower part of the sigmoid, probably a mural abscess. After considerable difficulty, enough of the sigmoid proximal to the diseased area of the bowel was freed, and four drains were inserted.

CASE 7.—D., a man, aged 49, five months previous to examination in 1925 complained of a dull dragging pain in the lower left side of the abdomen, accompanied by fever (102). Daily irrigations of the lower bowel with rest in bed for two weeks gave complete relief. Several weeks ago the patient had attacks of intermittent pain in the lower left side of abdomen again, accompanied by fever, and relieved in a few days by colonic irrigations. Pain was relieved, but tenderness persisted in the lower left quadrant. The bowels were always regular. He noted some mucus and what he thought was pus in the stools. He lost 30 pounds (13.6 Kg.) in three months. A similar attack occurred four years ago, with pain in the left lower part of the abdomen, fever, and some blood in the stools.

Examination of the abdomen revealed a mass in the left lower quadrant, about 4 inches long and 2 inches wide, tender on palpation. Preoperative diagnosis of diverticulitis with possible malignant degeneration was made. Operation was performed, and a hard nodular tumor resembling carcinoma was found, attached just above the brim of the pelvis on the left side, in the proximal limb of the sigmoid. Resection of the sigmoid was done. Pathologic examination revealed a chronic inflammatory process with no evidence of a malignant condition.

Three months later, the patient was readmitted, presenting a small discharging sinus. He was feeling much improved and had gained in weight. A small abscess was found just below the old opening, and the entire infected area was excised. Recovery was complete.

CASE 8.—A. M. H., a man, aged 60, presented himself for examination in 1909. He gave a previous history of ischiorectal abscess in 1888, which was opened. He had a cosmetic operation afterward. Constipation had been present since then.

In 1901 he had slight rigor with pain in the anus. In 1902 he had a severe attack of chills and fever, tenesmus and severe local pain with discharge of pus. This subsided and was soon followed by another similar attack. In the hospital a retention catheter was passed, and the patient suffered a great deal. He continued to suffer with chills and fever; catheterization was employed several times, and about this time he had pain over the pubis and the left iliac region. The abdominal muscles were rigid. His condition improved, but he passed some gas through the penis, which was attributed to infection with Welch bacillus. The patient had had three or four attacks since 1902. In 1908 he had a severe attack with chills, fever, exhaustion and passage of gas through the penis. Early in 1909, he was examined by Dr. Pederson, who thought he noticed a depression in the bladder. In June 1909, the patient suffered from irritation of the bladder with desire to urinate and tenesmus, which was followed by chills and fever and passage of feces and gas through the penis. Another attack occurred in August.

Operation revealed a large mass, occupying the middle and left portion of the pelvis, which was discovered to be the omentum closely adherent to the sigmoid and bladder. After the omentum was dissected off and the sigmoid lifted up, the fistulous opening into the bladder was seen, and the fistula was dissected out of the bladder and the bladder closed. The sigmoid was found to be enormously thickened. Colostomy was done at the site of the fistulous tract and a catheter was inserted into the bowel. The patient made a good recovery.

The following report gives the observations made at autopsy in a case of diverticulitis:

Postmortem examination of the colon revealed an indurated thickened mass, about 20 cm. above the anus, which completely surrounded the sigmoid, which was 5 or 6 cm. in length, and caused marked stenosis at the intestine at this place, so that even the little finger could pass through it. On the peritoneal surface there was seen a circular starlike constricting mass, and when the intestine was opened there were found, projecting into the lumen just below this constriction, somewhat polypoid, edematous, beginning gangrenous finger-like projections of the mucosa, from 1 to 2 cm. in diameter and several centimeters in length. This constricting area was cut through with difficulty, and it cut like firm fibrous tissue. When this portion was laid open, the mucosa for a length of about 10 cm. was thrown up into large folds which were edematous and dark red, and some were in the early gangrenous stage. No neoplasm could be found at this region and no ulcerations. The wall of the sigmoid was much thickened and infiltrated by firm radiating bands of tissue, which were fibrous in consistency. Immediately below the constriction, for a distance of about 5 cm., were found several circular openings in the mucosa, several millimeters in width, into which a probe could be inserted for a distance of from 1 to 2 cm., evidently sigmoid diverticula, but which do not project beyond the serosa. Immediately above the constriction were found eight or ten similar small diverticula and through the remainder of the large intestine were found about a dozen more. No definite relationship could be made out between these diverticula and the blood vessels, but most of them occurred along the situation of the mesenteric attachment. The openings into these diverticula were lined with smooth mucosa, none of them being ulcerated or gangrenous. Many were filled with feces. The entire colon was filled with semisolid feces. The caput was tremendously distended; its mucosa was reddened, the serosa was purplish. The site of colostomy was in good condition. A portion of the rectum below the constricting area already described was removed separately. The mucosa was somewhat dilated, smooth and pale; in its upper portion it did not show any diverticula, and the portion 5 cm. above the anus was much reddened and was edematous.

Of 16,283 autopsies done at Bellevue Hospital between 1904 and 1930, many of which were limited to the head or the chest, there were 169 cases of diverticulosis and diverticulitis. At the Mayo Clinic, in one third of all the patients examined roentgenographically, diverticulitis or diverticulosis was present.

New ideas are not plainly accepted by medical men. Time, patience and wide publicity are required before general acknowledgment of worth is given to any new routine. This may be both fortunate and unfortunate; fortunate in being "sure you are right before you go ahead," and unfortunate when years are lost before accepting true value. After 230 years, diverticulitis is now more frequently diagnosed and recognized as a surgical disease. While its origin is not yet settled, this is not of great moment. The important thing is in the recognition of the prediverticulitis stage.

Medical treatment of diverticula is an inherited misconception that it has been difficult to overcome.

There is no more chance of aborting diverticulitis by diet than of aborting appendicitis.

Structural defects are surgical and not medical problems.

205 East Sixty-First Street.

ABSTRACT OF DISCUSSION

Dr. Dudley D. Roberts, New York: I can't overlook this opportunity of disagreeing with my friend Dr. Lynch in several particulars. He has stated that in his opinion colonic diverticulosis is a congenital condition. While in a sense this may not seem especially important, such a view fails to take adequate notice of the fact that colonic diverticulosis is especially a disease of middle and old age and occurs in the obese in a preponderating proportion of instances. This fact must not be lost sight of in the differential diagnosis of abdominal complaints. A lower left-sided abdominal pain in a corpulent patient should give rise to a suspicion of diverticulosis or diverticulitis. My opinion is that a fatty infiltration of the wall of the colon is the most probable cause of these multiple pouchings. Again, he said that there was no medical treatment for diverticulosis and diverticulitis. Such a view overlooks the fact that for a number of years massive doses of barium have been used with the greatest success in relieving the discomforts associated with diverticulosis and even in bringing about a betterment of a secondary inflammatory process in the affected area. This is too important a remedy by far to be passed over casually or entirely overlooked. Dr. Thomas Brown has twitted New York with good reason on its devotion to so-called colonic irrigation. I agree that too much cannot be said in condemnation of this as such a general practice. Its actual danger is sometimes seen in acute perforations of diverticula with local peritonitis. This was forcibly called to my attention this winter when within a period of a fortnight two patients were seen in consultation with what was obviously a peritonitis from a ruptured diverticulum. The condition had been unrecognized and both patients had been having colonic irrigations for several days. The cessation of this treatment was followed by entire recovery in the one case without operative treatment. In the second case general peritonitis had already supervened. It seems extremely probable that under some conditions the introduction of any considerable quantity of water into the rectum might well result in the spread of walled off peritonitis when it has resulted from a ruptured diverticulum in the sigmoid. This should be a matter of more general recognition.

Dr. Julius Friedenwald, Baltimore: While most diverticula do not produce symptoms and are usually only accidentally discovered, they may occasion on the other hand symptoms of a most distressing and even serious type. Those that produce symptoms are ordinarily situated in the colon in the region of the sigmoid. It is in this area that infection is most likely to occur, a condition which is the usual cause for the production of symptoms. The symptoms are often misleading and are frequently attributed to mucous colitis, intestinal indigestion and the like. They may, however, become prominent. In acute diverticulitis, the symptoms resemble those of acute appendicitis situated on the left side. In the less acute forms, the pains may be moderate and are not infrequently associated with disturbances of the bladder; in others, they may be of an obstructive character; in still others, of ulceration, abscess formation and even perforation. The differential diagnosis between carcinoma and chronic diverticulitis is often difficult and, as William Mayo has pointed out, carcinoma may even develop on the basis of a diverticulum. A point in differential diagnosis is that in chronic diverticulitis bleeding is uncommon, while it is frequent in carcinoma. Diverticulitis is easily detected by means of the x-rays, the diverticula retaining the barium, frequently for days following its complete expulsion from the intestine. Small rounded shadows can be noted in the affected areas. It is important in doubtful instances to examine the patient sometime following the evacuation of the barium, that is, on the second or third day, for the lumen of the bowel may be so completely filled with this substance as to obscure the actual condition. In a woman, aged 50, under my care, in whom, because of recurrent attacks of left-sided pain associated with severe constipation and extreme tenderness in the left lower quadrant of the abdomen, diverticulitis was suspected, the roentgen diagnosis of mucous colitis was reported. The pain continued, and since it radiated into the left lumbar region, a cystoscopic examination was advised ten days later. In the course of this examination, at which roentgenograms were again taken, the urologist noted a well advanced diverticulitis of the sigmoid. It was evident that the intestine was still so completely filled with barium at the time of the first examination as to obscure the real picture. When diverticulitis is suspected and not detected at the first roentgen examination, the bowel should be completely emptied of the barium and another examination made a day or two later, when the diverticula, if present, will still be found filled. If the diagnosis, however, still remains doubtful, one should take advantage of the combined method, consisting of the barium enema and air inflation as advised by Fisher and recently by Weber, by means of which not only polypi but also diverticula can be more certainly visualized. In the treatment, when the acute condition occurs, one is faced with the same problem as that of acute appendicitis and the question of immediate surgical intervention must always be considered. However, in the more chronic cases in which the symptoms do not appear urgent, large doses of barium taken once or twice weekly are often exceedingly valuable in relieving the symptoms as well as in arresting the progress of the condition. Operative intervention should be advised in intractable cases.

RADIOTHERAPY AND SURGERY IN ADVANCED CANCER OF THE BREAST *

ISAAC LEVIN, M.D.
NEW YORK

Clinical experience of over a quarter of a century has firmly established the efficacy of surgery, radium and x-rays in the treatment of cancer generally. However, the relative importance of surgery and irradiation varies with the different types of cancer. To take two instances: The clinical study of the last two decades has definitely established the fact that, in cancer of the cervix, irradiation gives results superior to surgery, and the former is today the method of choice. In cancer of the breast, on the other hand, surgery remains the most important therapeutic method, and irradiation is second in importance. This striking phenomenon is, in my opinion, due to the difference in the clinical course of these two types of cancer.

Cancer of the cervix invades the surrounding normal tissues (rectum, urinary bladder, ureters and blood vessels) and regional lymph nodes. Very rarely are metastases formed in distant regions and then only late in the course of the disease.

In carcinoma of the breast, metastases in the distant regions (lymph nodes, lungs, skeleton, liver) appear frequently and early in the course of the disease.

In view of this clinical behavior and the proximity of vital organs to the cervix, surgery will more readily leave behind remnants of cancerous tissue than irradiation, which may at a distance destroy all the cancerous tissue while it leaves the adjoining normal tissue intact.

In cancer of the breast there is less danger of injuring vital organs, and the surgical procedure may be more complete. Furthermore, surgery acts promptly in removing the whole tumor and thus stops immediately the metastatic transportation of tumor tissue, while irradiation acts comparatively slowly and leaves ample time for such transports.

This clinical behavior of cancer of the breast is far from being true in every instance. In reality, various types of cancer of the breast differ greatly in their clinical course, showing greater or lesser rapidity of the local growth and great variations in the frequency of the occurrence of distant metastases. A scirrhous carcinoma of the breast may remain localized for years without disturbing the rest of the organism, while a medullary carcinoma may kill the patient in a few months or even weeks. In some cases the carcinoma of the breast which appears to be in a comparatively early stage will recur locally soon after a most radical operation, and throughout the whole subsequent course of the disease no distant metastases will be noted anywhere. In other cases the result of the operation will be apparently perfect; there will be no local recurrence and yet, as late as twenty-years after the operation, a metastasis will occur in the head of a femur or in the pelvic bones.

Experimental as well as clinical investigations which I [1] have made on the mechanism of formation of metastases in cancer indicate that a secondary metastatic tumor forms only when the transported cancer cells succeed in overcoming the inhibiting powers of the normal tissues of the new locus. Otherwise it may be surrounded by a connective tissue barrier and destroyed. This phenomenon has a practical significance. When the areas in which one knows by experience that metastases occur are irradiated prophylactically, it is sufficient to suppress the proliferating power of the implanted cancer cells without actually killing them.

Notwithstanding these clinical differences, the early formation of metastases is the preponderating manifestation of malignancy in cancer of the breast, and therefore surgery remains the most important method of therapy.

ADVANCED CANCER OF THE BREAST

The next point to determine is whether surgery alone without the aid of radiotherapy ever suffices in a fully developed cancer of the breast. Many surgeons still maintain that irradiation adds nothing to the results of a radical mastectomy.

In 1929, a committee on the treatment of malignant diseases with radium and x-rays of the American College of Surgeons reported [2] on cancer of the breast. The committee has tabulated statistically 774 cases from nine hospitals in four towns. The general conclusion was reached that roentgen treatment does not add anything to the results of radical surgery in the early cases but that the value of x-rays in the treatment of recurrence after operation is established. These two conclusions are evidently contradictory, to say the least. If results can be obtained when a recurrence is already established, it should be easier to succeed when the treatment is begun before the recurrence appears and when there are consequently only microscopic islands of cancer cells to overcome. The only plausible explanation of this discrepancy is that in series of cases studied by the committee the recurrences were irradiated properly while the prophylactic irradiation, on the other hand, was given in a half-hearted manner. Indeed, the committee admits that an accurate statement of the details of roentgen treatment is not possible. "At times low voltage was given, in other hospitals 'more penetrating' radiation was available. Radium was used in only a very small number of cases."

As a result of a quarter of a century of study, covering a large number of cases of cancer of the breast in clinic, hospital and private practice, I can fully subscribe to the following statement of Dr. W. Sampson Handley.[3]

> The key to further advances in the operative treatment of malignant disease is *not* to be found in statistical studies in which large numbers of cases are *superficially* studied. It is in the ward and laboratory rather than in the bureau of health statistics that the information we require is to be *sought*.

In the present paper I shall deal with the advanced cancer of the breast and not with early cancer, and for the former the value of irradiation is admitted even by the committee of the College of Surgeons. Moreover, these statistical investigations reveal the following most important phenomena: Of the 774 cases studied by the committee, about 15 per cent showed no glandular involvement, and of these patients about 57 per cent, or about 8 per cent of the whole number, remained well for five years. The involvement of the axillary lymph nodes was present in 33 per cent, and of these only 16 per cent, or about 5 per cent of the whole number of patients, remained well for five years after a radical operation.

---

* Read before the Section on Radiology at the Eighty-Second Annual Session of the American Medical Association, Philadelphia, June 11, 1931.

[1] Levin, Isaac: J. Exper. Med. **18**: 397, 1913; Proc. Path. Soc. **15**: 8, 1915; Ann. Surg. **65**: 326 (March) 1917; J. Nerv. & Ment. Dis. **45**: 481 (June) 1917.

[3] Handley, W. S.: Surg., Gynec. & Obst. **45**: 721 (Dec.) 1927.

This statistical analysis shows that a cancer of the breast in which the axillary lymph nodes are involved is an advanced cancer of the breast and, further, that no more than 13 per cent of all the 774 patients whose cases were analyzed remained well five years after the operation, and therefore 87 per cent of all cases of cancer of the breast which come for treatment are advanced cases. These advanced cancers of the breast and not the early cases present today the chief problem in therapy.

Different types of advanced cancer of the breast show different grades of malignancy, take a different clinical course and require different methods of treatment. Broders[4] has initiated a morphologic classification of grades of malignancy. Lee and Stubenbord,[5] however, have shown that, in cancer of the breast, histologic grading of malignancy is far less effective than clinical grading, and my experience fully coincides with this conclusion.

In order to discuss systematically the relative therapeutic value of surgery and irradiation in advanced cancer of the breast, it is best to classify the types of cancer into groups and discuss each group separately. The following eight groups may be considered: (1) primary tumor movable over the chest wall and the axillary lymph nodes involved; (2) similar to group 1 but with involvement of supraclavicular or infraclavicular lymph nodes; (3) similar to group 2, but with ulceration of the primary tumor; (4) primary tumor attached to the chest wall; (5) local recurrence after a radical mastectomy; (6) metastases in the lungs; (7) metastases in the skeleton, and (8) metastases in the liver.

Each of these groups requires a different therapeutic technic and will therefore be discussed separately.

METASTASES IN AXILLARY LYMPH NODES

As previously stated, when the lymph nodes in the axilla are involved, the condition must be considered an advanced cancer of the breast; surgery alone succeeds in only about 16 per cent of the cases in which operation is performed, and the aid of irradiation is quite evidently indicated.

Whenever both the tumor of the breast and the one in the axilla are freely movable over the chest wall and the underlying tissues, the case is an operable one and requires an immediate radical mastectomy.

Preoperative irradiation should not be given in this type of case, since it would delay the operation. Occasionally the patient may even subsequently refuse the operation and insist on the continuation of the radiotherapy.

On the other hand, postoperative irradiation should begin immediately after the operation; in fact, simultaneously with it.

I begin the treatment of these cases with a radical mastectomy and, if the axillary lymph nodes show actual involvement, I then place buried capillaries of radon in the axilla and in the parasternal regions. This is followed subsequently by a course of high voltage roentgen treatment and surface application of radium.

The superiority of this planned systematic combination of surgery with irradiation over unsupported surgery is self evident, since the value of irradiation therapy in the treatment of recurrences is admittedly established.

Again it is extremely difficult to offer irrefutable statistical evidence, particularly since even five years' cure does not mean that the condition may not return as a local recurrence or a metastasis.

The ability to keep the disease in check for a long period of time in a number of cases is a valid proof of the efficiency of a therapeutic measure. Handley[3] devotes the major part of his paper to the presentation of the clinical course of one patient who had a left mastectomy done in 1912, followed by roentgen treatments and radium insertions. Ten years later, a right mastectomy was done. The patient died two years later, or twelve years after the first operation, from metastases in the lungs. The patient remained active and well till two weeks before death. This case shows clearly the efficiency of radium therapy. The following are cases of a similar character which I have treated:

CASE 1.—E. C., a woman, aged 24, was admitted to the hospital, April 29, 1921, with carcinoma of the left breast and a large tumor in the axilla. I did a radical mastectomy and inserted capillaries of radon into the axilla and the part of the chest wall corresponding to the breast tumor. This was followed by roentgen treatment and surface application of radium. No metastases were found at the time of operation in the lungs, skeleton, liver or the other breast.

In October, 1923, a tumor was found in the right breast, with involvement of the axilla. I did a mastectomy of the right breast, with insertion of radon, which was then followed by roentgen treatment and surface application of radium. The patient died, Jan. 10, 1929, nearly eight years after the first operation, of pulmonary metastases. With the exception of the last few weeks, the patient was well throughout the eight years and worked, supporting herself and her child.

CASE 2.—B. B., a woman, aged 49, was admitted to the hospital, June 26, 1920, with carcinoma of the right breast, and a radical mastectomy was done. Carcinoma was found in the axillary lymph nodes. A carcinoma nodule was also found in the right parasternal region corresponding to the third rib. I immediately placed capsules of radium over the parasternal region and in the axilla. Since then, the patient has had several courses of roentgen therapy and surface application of radium. Today, eleven years since the mastectomy, the patient is clinically well and shows no evidence of recurrence or metastases.

In the first group of cases of advanced cancer of the breast, a certain though small percentage of cases may be cured and therefore this is the primary aim in this group. A complete radical mastectomy must be done and generally an attempt made at complete eradication of the disease. All the other groups to be discussed later are beyond any chance of complete recovery, and the aim of therapy is prolongation of life and creation of a useful or at least comfortable life. In other words, the treatment is, in the main, palliative.

METASTASES IN SUPRACLAVICULAR LYMPH NODES

When cancer of the breast shows the involvement of both the axillary and supraclavicular (less frequently infraclavicular) lymph nodes, the chances of complete recovery are minimal. None the less, a mastectomy should be done when the primary tumor is movable over the chest wall. A separate incision is made over the clavicle, and radon capillaries are inserted in the axilla, the supraclavicular region and the chest. This is followed by high voltage roentgen therapy and surface application of radium. I have had a number of patients who lived in comfort for three or four years with such treatment. But they all ultimately succumb to the disease.

ULCERATED CANCER OF THE BREAST

In the previous two groups, surgery remains the major method of therapy and the irradiation a very important adjuvant which must follow and not precede surgery. In the following groups the irradiation is the major procedure, it always antecedes surgery, and the latter is employed only occasionally.

A patient suffering from a large ulcerating tumor of the breast which constantly secretes a foul discharge is a burden to herself and to her surroundings. When there is no evidence of multiple metastatic nodules in the skin surrounding the ulcerating tumor, the case is treated in the following manner: An insertion of radon capillaries is made into and around the ulcerated area of the tumor, and this is followed by surface applications of radium and by roentgen therapy. After a period of from four to six weeks, the ulcer generally becomes diminished in size and the tumor becomes more freely movable over the chest wall. A mastectomy is then done, with the removal of the pectoral muscles and with a more or less complete cleaning of the axilla, depending on the conditions found. Only enough skin is removed to excise widely the ulcerated area and to allow for an immediate primary union.

It must be clearly understood that this represents only a palliative procedure. It seems, however, not only to prolong life but mainly to make the life of the patient more bearable. It is much more comfortable for the patient, both bodily and mentally, to succumb ultimately to metastases than to live for months with a large fungating carcinomatous ulcer.

The following cases serve to illustrate this group:

Case 3.—S. C., a white woman, aged 69, was admitted to the hospital, May 22, 1924, with advanced cancer of the right breast. On examination there was found a stony hard mass in the upper half of the breast. It was about the size of a grapefruit and was attached to the skin but was movable off the deep structure. There was an ulceration, roughly circular and 6 cm. in diameter, overlying the central part of the tumor. The right nipple was drawn upward toward the tumor. In the right axilla there was a large stony hard mass which was movable over the underlying tissues. No distant metastases were noted. The diagnosis was proved microscopically. June 21, radon capillaries were inserted into the ulcerated area of the breast. The tumor shrank, and the ulceration diminished in size. A mastectomy was performed, July 24. The wound healed by primary union and the patient improved rapidly in her general condition. When she was last seen, sixteen months after the operation, there was no evidence of any local recurrence or metastases.

Case 4.—M. D., a white woman, aged 77, was admitted to the hospital, Aug. 3, 1929, with an advanced cancer of the right breast. On examination the right breast appeared smaller than the left and was pulled to the right and upward. About 3 cm. above and to the right of the nipple there was noted a round ulcer, 2 cm. in diameter, somewhat elevated above the surface of the breast, and of a pinkish red. On palpation the base of the ulcer was very hard and was attached to a diffuse mass which occupied the right upper quadrant of the breast. The right axilla contained several lymph nodes hard in consistency. The diagnosis of carcinoma was proved microscopically. August 27, capillaries of radon were inserted into the ulcerated area of the tumor. September 5, the mass diminished in size and became softer in consistency. October 29, a mastectomy was done. The wound healed by primary union, and the local and general condition has been good since.

In all these cases the mastectomy was followed by high voltage roentgen therapy and surface application of radium.

BREAST TUMORS ATTACHED TO THE CHEST WALL

In all the cases of the fourth group the tumor is attached to the chest wall and, as long as this condition lasts, surgical removal is contraindicated, since a severe local recurrence would follow the operation. In this group, therefore, radiation therapy is the only method to employ in the majority of cases. Whether the primary breast tumor is ulcerated or not, an insertion of radon should be made into the primary tumor and into the metastases in the axilla, which are always present in these cases. This is followed by high voltage roentgen therapy and surface application of radium. The tumor usually shrinks under this treatment, and the ulceration is covered with an epidermis.

In a certain number of these cases the tumor not only shrinks but becomes movable over the chest wall. In such an instance a palliative mastectomy may be performed with temporary benefit and possible prolongation of life. In the following cases the tumors became movable after the intratumoral insertion of radon:

Case 5.—M. E., a white woman, aged 63, was admitted to the hospital, May 21, 1925, with advanced cancer of the right breast. On examination of the right breast, the nipple was found replaced by a hard indurated mass. Another mass was noted in the lower outer quadrant of the breast, ulcerated in the center. The masses were firmly adherent to the chest wall. The diagnosis of carcinoma was proved microscopically. June 10, a radon insertion was done into the two carcinomatous masses of the breast. This was followed by high voltage roentgen therapy. August 3, the tumors were found to be freely movable over the chest wall, and on August 12 a palliative mastectomy was done. The wound healed by primary union and when the patient was seen last, eighteen months later, there was no evidence of any local recurrence or metastases.

Case 6.—G. M., a white woman, aged 60, was admitted to the hospital, Feb. 29, 1924, with advanced cancer of the left breast. On examination of the left breast there was noted in the upper outer quadrant a tumor mass measuring 6 by 2 cm., firmly adherent to the chest wall and ulcerated in the center. No metastases were found in the chest or skeleton. March 27, radon capillaries were inserted into the tumor. On April 14 and still more on April 29, the tumor appeared smaller in size and freely movable over the chest wall. May 8, the mastectomy was done, the wound healed and the patient left the hospital. Feb. 3, 1925, roentgen examination showed the appearance of skeletal metastases. The patient died, May 5, about fifteen months after the beginning of the treatment.

This purely palliative treatment of these patients certainly added greatly to their comfort.

LOCAL RECURRENCE AFTER MASTECTOMY

Recurrent tumors in the mastectomy field are most usually adherent to the chest wall and therefore, like the tumors in group 4, must be treated by irradiation. The only surgical procedure in this type of case consists in an incision over the tumor mass so as to facilitate the intratumoral insertion of radon and possibly in doing a biopsy. Only temporary improvement may be obtained in this group of cases.

None the less, as may be seen from the following case, very satisfactory results may follow this course of treatment:

Case 7.—A. E., a woman, aged 58, had a radical mastectomy done for carcinoma of the left breast with involvement of the axilla, in September, 1926. Oct. 31, 1927, a local recurrence appeared in the sternocostal junction corresponding to the third and fourth rib. I made an incision over the tumor mass, performed a biopsy, which gave positive results, and did an insertion of radon capillaries. This was followed by high voltage roentgen therapy and surface application of radium. At present, nearly five years after the mastectomy, there is no evidence of any local recurrence or metastases anywhere, and the patient is comfortable and takes care of her work.

METASTASES IN THE LUNGS

The life of a patient with pulmonary metastases secondary to a cancer of the breast is short and extremely uncomfortable. The condition is hopeless, and, as a general rule, irradiation does not improve it. None the less, all these patients should be given the benefit of radiotherapy, since occasionally striking temporary improvement may be obtained, as is well seen in the following case:

Case 8.—M. P., a white woman, aged 39, was admitted to the hospital, March 25, 1930, with a history of having noticed a mass in the right breast eighteen months previously and an ulceration for the last six months. The patient also complained of dyspnea and cough.

On examination the right breast was transformed in its entirety into a flat hard and nodular tumor mass, irregularly round in outline, measuring about 15 cm. in diameter and about 3 cm. in thickness, firmly adherent to the chest wall. Surrounding and partly undermining the nipple there was a flat ulceration measuring about 8 cm. in diameter. A hard and nodular tumor, measuring 3 cm. long and 2 cm. thick, was found in the axilla. On percussion of the chest the right side showed dulness everywhere and on auscultation total loss of breath sounds.

Roentgen analysis showed an opacity throughout the right side, with the exception of a small area just beneath the inner aspect of the clavicle. No distant metastases were found elsewhere. A diagnosis of carcinoma of the breast with metastases to the pleura and lungs was made. March 27, a thoracocentesis was done and 1,000 cc. of straw colored fluid was obtained; then a specimen of tissue for a biopsy was taken from the ulcerated area, which confirmed the diagnosis, and radon capillaries were inserted into the tumor of the breast and of the axilla. June 20, the thoracocentesis and the radon insertion were repeated. This was followed by roentgen and surface radium therapy. No further thoracocentesis was necessary; the ulcerated area is covered with skin, and in the last roentgen analysis of the right lung the tissue appears clear throughout the upper and middle lobe. Neither the tumor of the breast nor the one in the axilla was palpable at the time. The patient lost her distressing symptoms of cough and dyspnea and felt clinically well without any evidence of local recurrence or metastases elsewhere until April, 1931. Then, suddenly symptoms of cerebral metastasis developed, and she died, April 16.

The therapeutic result of irradiation in this case was certainly remarkable, and had it not been for the cerebral metastasis which is comparatively infrequent in cancer of the breast, the patient's life might have been prolonged still further.

SKELETAL METASTASES

Most remarkable results are obtained occasionally in the treatment of skeletal metastases of carcinoma of the breast by the aid of surface application of radium and roentgen therapy. I have already reported several such cases, but the following case may be added:

Case 9.—T. C., a woman, aged 36, who entered the hospital, March 22, 1922, was suffering with paraplegia and complained of severe pain in her back and inability to move. Roentgen analysis showed diffuse metastases of the skeleton, involving the dorsal and lumbar spine and all the pelvic bones, as well as the skull. Subsequently the cervical spine also became involved, so that the patient was lying rigid in bed without being able to move either the lower extremities or the head. At one time, respiration became extremely difficult. The patient remained at the hospital for two and one-half years until late in November, 1924. In the course of her stay at the hospital, she received surface radium applications and roentgen treatments practically throughout her whole skeleton. She gradually began to improve, so that toward the end she was able to walk about without any support or help, had practically no pain anywhere, and at her own request she was discharged in November, 1924. Examination of the skeleton revealed a great deal of new bone formation throughout the skeleton, which apparently made the spine firm and healed the clinical paraplegia.

This case is very remarkable in view of the complete generalization and immense amount of metastatic carcinoma throughout the organism and also in view of the large amount of therapy that the patient received in the course of two and one-half years. The clinical result is very striking. While it is fairly certain that the carcinoma tissue had not all been destroyed within the organism, a bedridden patient with paralysis of both lower extremities, with severe pain on the least movement of any joint, was able to leave the hospital in a condition in which she could walk about and take care of herself.

METASTASES IN THE LIVER

Metastases in the liver secondary to carcinoma of the breast usually indicate generalized carcinomatosis of the organism, and such patients are therefore beyond any type of specific therapy.

In all types of advanced cancer of the breast, it is necessary to examine at frequent intervals the lungs, liver and skeleton, and to change the methods of treatment or to cease treatment entirely, depending on the condition.

It is important to know in this connection that in a patient in apparently good general condition, and suffering possibly only from local recurrence, gastric symptoms may suddenly develop, with severe uncontrollable vomiting. This is frequently the first symptom of the development of metastasis in the liver.

SUMMARY

About 87 per cent of all patients with cancer of the breast come for treatment when already in the advanced stage of the disease.

However, distressing symptoms may be relieved and life prolonged considerably in many of these advanced cases by proper coordination between surgery, radium and roentgen therapy.

Different types of advanced cancer of the breast require different methods of therapy. They may all be divided into the following groups:

1. Cases showing metastases in the axillary lymph nodes. The primary tumor is movable over the chest wall and no distant metastases are present.
2. Cases similar to those in group 1, but with metastases present in the supraclavicular or infraclavicular regions. In these two types of cases, surgery should be the first step. The surgical procedure should be radical, and active irradiation should follow immediately.
3. Tumors which are ulcerated, but movable over the chest wall. In this type, radiotherapy should precede and follow surgery. Though palliative, very satisfactory results may be obtained.
4. Tumors attached to the chest wall. Radiotherapy is the first step. Only if the tumor becomes movable over the chest wall may surgery follow.
5. Local recurrence after radical mastectomy. These cases should be treated in the same manner as the tumors in group 4. Results in groups 4 and 5 may be as good as in group 3.
6. Cases with metastases in the lungs. These cases should all be treated by radiotherapy, since occasionally a good temporary result may be obtained.

7. Cases with metastases in the skeleton. Radiotherapy should be used, for the same reason as in group 6.

8. Cases with metastases in the liver or with generalized carcinomatosis. These cases are beyond any type of therapy.

At present not the early but the advanced cancer of the breast presents the most pressing therapeutic problem.

57 West Fifty-Seventh Street.

ABSTRACT OF DISCUSSION

Dr. Leon T. Le Wald, New York: Dr. Pfahler in his statistics has made the statement that after five years he has had 30 per cent of the patients free from disease after radiation treatment of primary inoperable cancer of the breast. This is an interesting percentage as against the various surgical percentages. The surgical statistics that I have heard vary from 16 per cent of five-year cures to somewhere in the thirties; so that when one matches these statistics one finds that radiation therapy holds its own versus surgery, even in certain cases that are regarded as operable. In the operable cases, various statistics do not give much more than 22 per cent of five-year cures following operation. Dr. Burton J. Lee has now a series of operable cases in which the patients have been treated by irradiation alone with a favorable outcome. Dr. Levin has been fair in stating that he would have the first group operated on prior to radiation but have the radiation therapy applied immediately following or at the same time in the open wound, inserting radon or using other methods of applying radium. As a neutral party I feel that he has amply proved his point.

Dr. George E. Pfahler, Philadelphia: We agree that if cancer of the breast is strictly confined to the breast, the surgeon can certainly take it away. Some men point to as high as 100 per cent recoveries in such cases, but only after they have passed the specimen to the pathologist and he has made a careful study do they find that the disease is confined to the breast. Then if the disease is found to have spread to the axilla, it is not classed as a case of primary carcinoma of the breast. That is all very well scientifically, but it doesn't apply so well to the individual woman who comes to us for advice as to treatment. When there are palpable lymph nodes in the axilla or the supraclavicular region, preliminary irradiation by means of the x-rays before operation would give the greatest chance of recovery. Dr. Lee showed, in a symposium before the American Radium Society two days ago, that in about 42 per cent of the cases in which there were no palpable lymph nodes metastasis was still found in the axilla. Therefore one must assume that even though lymph nodes are not palpable such lymph involvements are liable to be present, and one must treat on that basis. That is the reason for considering an early case from a radiologic standpoint. Samson Handley says that when a case of cancer of the breast comes to the surgeon it is already an intrathoracic disease. The preliminary irradiation, consisting of 100 or at least 90 per cent of an erythema dose given over the axilla and supraclavicular region, over the mediastinal space and perhaps over the breast areas, though that is less important, will be helpful in preventing recurrences. I reported before the American Radium Society on 1,022 cases of carcinoma of the breast that were treated by irradiation. The best results were obtained in the cases in which surgery and irradiation were combined when axillary lymph nodes were involved. That applies, as Dr. Levin has said, to at least 87 per cent. Dr. Lee estimated the group that comes with the disease confined to the breast as 6 per cent; therefore, 94 per cent must be considered in relation to metastasis. In cases in which we had irradiation combined with surgery (inoperable cases with lymphatic involvement), 56 per cent were symptom-free at the end of five years. The successful results from irradiation in that group of cases are somewhere between 15 and 22 per cent, but even if one takes the highest point, 22 per cent, one still gets two and one-half times as many well as one will if he adds to the irradiation the primary cases.

Dr. William Harris, New York: I should like to bring up a point that concerns implanting the axilla with radon seeds after radical mastectomy. One is impressed by the rare occurrence of palpable disease in the axilla after this operation, even after it is known that the carcinoma has not all been removed from the axilla and also in patients in whom metastatic disease may be widespread throughout the body. I should be grateful for discussion on this point.

Dr. Isaac Levin, New York: I selected Dr. Le Wald to open the discussion since I wanted him to act as umpire between surgeons and radiologists, an office which he filled in St. Luke's Hospital in New York with success for many years. If I had had my present experience when I was young, I should have settled in Philadelphia, where Dr. Pfahler can give leisurely preoperative irradiation without encountering any interference from the general surgeons. In New York if one general surgeon is willing to wait for the operation until the irradiation is completed, another less painstaking surgeon will proceed with an operation frequently incomplete and unsatisfactory in its nature, or even an unnecessary one. Years ago I reported a series of cases of carcinoma of the breast in which skeletal metastases were present at the time the radical mastectomy was performed. I therefore advised that a roentgen analysis of the skeleton be done before every radical mastectomy. The patient will be served best when the operation will be done expeditiously and irradiation done simultaneously with the operation. The insertion of buried or removable radon capillaries into the axilla in the course of a radical mastectomy does not add to the hazard of the operation; there is no sloughing, suppuration or any other disturbance. I have treated many patients with this technic in the last ten years, and I can state emphatically that such irradiation of the axilla offers no difficulty either to the surgeon or to the patient.

Clinical Notes, Suggestions and New Instruments

TRAUMATIC PNEUMOCEPHALUS

Charles F. Thompson, M.D., and Jewett V. Reed, M.D.
Indianapolis

At the meeting of the Philadelphia Neurological Society, Oct. 24, 1930, Miller, Klemmer and Snoke[1] reported a case of traumatic pneumocephalus and discussed the rarity of recovery following this condition. Including their case they could find only seven instances of recovery reported in the literature. Their table of recovery is copied herewith, to which is added our case.

Cases of Traumatic Pneumocephalus

Case Reported by	Cause of Condition	Cranial Air Sinus Involved	Recovery
1. Wolff, 1914...............	Bullet	Frontal	Operation
2. Potter, 1919...............	Fracture	Frontal	Spontaneous
3. Teachenor, 1923.........	Fracture	Mastoid	Spontaneous
4. Dandy, 1925..............	Fracture	Frontal	Operation
5. Dandy, 1925..............	Fracture	Mastoid	Spontaneous
6. [illegible]	Fracture	Frontal	Spontaneous
7. [illegible]	Fracture	Frontal	Operation
8. [illegible]	Fracture	Mastoid	Spontaneous

The following is a summary of our case of traumatic pneumocephalus: C. D., a man, aged 37, Negro, was taken to the Indianapolis City Hospital, Aug. 19, 1930, following an accident in which he fell about 15 feet, striking the right side of the head.

Examination showed the patient to be in a semiconscious condition. Above the right ear was an abrasion of the scalp. There was a profuse bloody discharge from the right ear. This blood did not clot, suggesting a mixture with cerebrospinal fluid. The right pupil was larger than the left. The patient was too stuporous to answer questions but he could be made to move both arms and legs voluntarily. The pulse was 60, the blood pressure 92 systolic and 54 diastolic, and respiration 18. Marked emesis was present.

---

tion of radon capillaries. This was followed by high voltage roentgen therapy and surface application of radium. At present, nearly five years after the mastectomy, there is no evidence of any local recurrence or metastases anywhere, and the patient is comfortable and takes care of her work.

METASTASES IN THE LUNGS

The life of a patient with pulmonary metastases secondary to a cancer of the breast is short and extremely uncomfortable. The condition is hopeless, and, as a general rule, irradiation does not improve it. None the less, all these patients should be given the benefit of radiotherapy, since occasionally striking temporary improvement may be obtained, as is well seen in the following case:

Case 8.—M. P., a white woman, aged 39, was admitted to the hospital, March 25, 1930, with a history of having noticed a mass in the right breast eighteen months previously and an ulceration for the last six months. The patient also complained of dyspnea and cough.

On examination the right breast was transformed in its entirety into a flat hard and nodular tumor mass, irregularly round in outline, measuring about 15 cm. in diameter and about 3 cm. in thickness, firmly adherent to the chest wall. Surrounding and partly undermining the nipple there was a flat ulceration measuring about 8 cm. in diameter. A hard and nodular tumor, measuring 3 cm. long and 2 cm. thick, was found in the axilla. On percussion of the chest the right side showed dulness everywhere and on auscultation total loss of breath sounds.

Roentgen analysis showed an opacity throughout the right side, with the exception of a small area just beneath the inner aspect of the clavicle. No distant metastases were found elsewhere. A diagnosis of carcinoma of the breast with metastases to the pleura and lungs was made. March 27, a thoracocentesis was done and 1,000 cc. of straw colored fluid was obtained; then a specimen of tissue for a biopsy was taken from the ulcerated area, which confirmed the diagnosis, and radon capillaries were inserted into the tumor of the breast and of the axilla. June 20, the thoracocentesis and the radon insertion were repeated. This was followed by roentgen and surface radium therapy. No further thoracocentesis was necessary; the ulcerated area is covered with skin, and in the last roentgen analysis of the right lung the tissue appears clear throughout the upper and middle lobe. Neither the tumor of the breast nor the one in the axilla was palpable at the time. The patient lost her distressing symptoms of cough and dyspnea and felt clinically well without any evidence of local recurrence or metastases elsewhere until April, 1931. Then, suddenly symptoms of cerebral metastasis developed, and she died, April 16.

The therapeutic result of irradiation in this case was certainly remarkable, and had it not been for the cerebral metastasis which is comparatively infrequent in cancer of the breast, the patient's life might have been prolonged still further.

SKELETAL METASTASES

Most remarkable results are obtained occasionally in the treatment of skeletal metastases of carcinoma of the breast by the aid of surface application of radium and roentgen therapy. I have already reported several such cases, but the following case may be added:

Case 9.—T. C., a woman, aged 36, who entered the hospital, March 22, 1922, was suffering with paraplegia and complained of severe pain in her back and inability to move. Roentgen analysis showed diffuse metastases of the skeleton, involving the dorsal and lumbar spine and all the pelvic bones, as well as the skull. Subsequently the cervical spine also became involved, so that the patient was lying rigid in bed without being able to move either the lower extremities or the head. At one time, respiration became extremely difficult. The patient remained at the hospital for two and one-half years until late in November, 1924. In the course of her stay at the hospital, she received surface radium applications and roentgen treatments practically throughout her whole skeleton. She gradually began to improve, so that toward the end she was able to walk about without any support or help, had practically no pain anywhere, and at her own request she was discharged in November, 1924. Examination of the skeleton revealed a great deal of new bone formation throughout the skeleton, which apparently made the spine firm and healed the clinical paraplegia.

This case is very remarkable in view of the complete generalization and immense amount of metastatic carcinoma throughout the organism and also in view of the large amount of therapy that the patient received in the course of two and one-half years. The clinical result is very striking. While it is fairly certain that the carcinoma tissue had not all been destroyed within the organism, a bedridden patient with paralysis of both lower extremities, with severe pain on the least movement of any joint, was able to leave the hospital in a condition in which she could walk about and take care of herself.

METASTASES IN THE LIVER

Metastases in the liver secondary to carcinoma of the breast usually indicate generalized carcinomatosis of the organism, and such patients are therefore beyond any type of specific therapy.

In all types of advanced cancer of the breast, it is necessary to examine at frequent intervals the lungs, liver and skeleton, and to change the methods of treatment or to cease treatment entirely, depending on the condition.

It is important to know in this connection that in a patient in apparently good general condition, and suffering possibly only from local recurrence, gastric symptoms may suddenly develop, with severe uncontrollable vomiting. This is frequently the first symptom of the development of metastasis in the liver.

SUMMARY

About 87 per cent of all patients with cancer of the breast come for treatment when already in the advanced stage of the disease.

However, distressing symptoms may be relieved and life prolonged considerably in many of these advanced cases by proper coordination between surgery, radium and roentgen therapy.

Different types of advanced cancer of the breast require different methods of therapy. They may all be divided into the following groups:

1. Cases showing metastases in the axillary lymph nodes. The primary tumor is movable over the chest wall and no distant metastases are present.
2. Cases similar to those in group 1, but with metastases present in the supraclavicular or infraclavicular regions. In these two types of cases, surgery should be the first step. The surgical procedure should be radical, and active irradiation should follow immediately.
3. Tumors which are ulcerated, but movable over the chest wall. In this type, radiotherapy should precede and follow surgery. Though palliative, very satisfactory results may be obtained.
4. Tumors attached to the chest wall. Radiotherapy is the first step. Only if the tumor becomes movable over the chest wall may surgery follow.
5. Local recurrence after radical mastectomy. These cases should be treated in the same manner as the tumors in group 4. Results in groups 4 and 5 may be as good as in group 3.
6. Cases with metastases in the lungs. These cases should all be treated by radiotherapy, since occasionally a good temporary result may be obtained.

7. Cases with metastases in the skeleton. Radiotherapy should be used, for the same reason as in group 6.

8. Cases with metastases in the liver or with generalized carcinomatosis. These cases are beyond any type of therapy.

At present not the early but the advanced cancer of the breast presents the most pressing therapeutic problem.

57 West Fifty-Seventh Street.

ABSTRACT OF DISCUSSION

Dr. Leon T. Le Wald, New York: Dr. Pfahler in his statistics has made the statement that after five years he has had 30 per cent of the patients free from disease after radiation treatment of primary inoperable cancer of the breast. This is an interesting percentage as against the various surgical percentages. The surgical statistics that I have heard vary from 16 per cent of five-year cures to somewhere in the thirties; so that when one matches these statistics one finds that radiation therapy holds its own versus surgery, even in certain cases that are regarded as operable. In the operable cases, various statistics do not give much more than 22 per cent of five-year cures following operation. Dr. Burton J. Lee has now a series of operable cases in which the patients have been treated by irradiation alone with a favorable outcome. Dr. Levin has been fair in stating that he would have the first group operated on prior to radiation but have the radiation therapy applied immediately following or at the same time in the open wound, inserting radon or using other methods of applying radium. As a neutral party I feel that he has amply proved his point.

Dr. George E. Pfahler, Philadelphia: We agree that if cancer of the breast is strictly confined to the breast, the surgeon can certainly take it away. Some men point to as high as 100 per cent recoveries in such cases, but only after they have passed the specimen to the pathologist and he has made a careful study do they find that the disease is confined to the breast. Then if the disease is found to have spread to the axilla, it is not classed as a case of primary carcinoma of the breast. That is all very well scientifically, but it doesn't apply so well to the individual woman who comes to us for advice as to treatment. When there are palpable lymph nodes in the axilla or the supraclavicular region, preliminary irradiation by means of the x-rays before operation would give the greatest chance of recovery. Dr. Lee showed, in a symposium before the American Radium Society two days ago, that in about 42 per cent of the cases in which there were no palpable lymph nodes metastasis was still found in the axilla. Therefore one must assume that even though lymph nodes are not palpable such lymph involvements are liable to be present, and one must treat on that basis. That is the reason for considering an early case from a radiologic standpoint. Samson Handley says that when a case of cancer of the breast comes to the surgeon it is already an intrathoracic disease. The preliminary irradiation, consisting of 100 or at least 90 per cent of an erythema dose given over the axilla and supraclavicular region, over the mediastinal space and perhaps over the breast areas, though that is less important, will be helpful in preventing recurrences. I reported before the American Radium Society on 1,022 cases of carcinoma of the breast that were treated by irradiation. The best results were obtained in the cases in which surgery and irradiation were combined when axillary lymph nodes were involved. That applies, as Dr. Levin has said, to at least 87 per cent. Dr. Lee estimated the group that comes with the disease confined to the breast as 6 per cent; therefore, 94 per cent must be considered in relation to metastasis. In cases in which we had irradiation combined with surgery (inoperable cases with lymphatic involvement), 56 per cent were symptom-free at the end of five years. The successful results from irradiation in that group of cases are somewhere between 15 and 22 per cent, but even if one takes the highest point, 22 per cent, one still gets two and one-half times as many well as one will if he adds to the irradiation the primary cases.

Dr. William Harris, New York: I should like to bring up a point that concerns implanting the axilla with radon seeds after radical mastectomy. One is impressed by the rare occurrence of palpable disease in the axilla after this operation, even after it is known that the carcinoma has not all been removed from the axilla and also in patients in whom metastatic disease may be widespread throughout the body. I should be grateful for discussion on this point.

Dr. Isaac Levin, New York: I selected Dr. Le Wald to open the discussion since I wanted him to act as umpire between surgeons and radiologists, an office which he filled in St. Luke's Hospital in New York with success for many years. If I had had my present experience when I was young, I should have settled in Philadelphia, where Dr. Pfahler can give leisurely preoperative irradiation without encountering any interference from the general surgeons. In New York if one general surgeon is willing to wait for the operation until the irradiation is completed, another less painstaking surgeon will proceed with an operation frequently incomplete and unsatisfactory in its nature, or even an unnecessary one. Years ago I reported a series of cases of carcinoma of the breast in which skeletal metastases were present at the time the radical mastectomy was performed. I therefore advised that a roentgen analysis of the skeleton be done before every radical mastectomy. The patient will be served best when the operation will be done expeditiously and irradiation done simultaneously with the operation. The insertion of buried or removable radon capillaries into the axilla in the course of a radical mastectomy does not add to the hazard of the operation; there is no sloughing, suppuration or any other disturbance. I have treated many patients with this technic in the last ten years, and I can state emphatically that such irradiation of the axilla offers no difficulty either to the surgeon or to the patient.

Clinical Notes, Suggestions and New Instruments

TRAUMATIC PNEUMOCEPHALUS

Charles F. Thompson, M.D., and Jewett V. Reed, M.D.
Indianapolis

At the meeting of the Philadelphia Neurological Society, Oct. 24, 1930, Miller, Klemmer and Snoke[1] reported a case of traumatic pneumocephalus and discussed the rarity of recovery following this condition. Including their case they could find only seven instances of recovery reported in the literature. Their table of recovery is copied herewith, to which is added our case.

Cases of Traumatic Pneumocephalus

Case Reported by	Cause of Condition	Cranial Air Sinus Involved	Recovery
1. Wolff, 1914	Bullet	Frontal	Operation
2. Potter, 1919	Fracture	Frontal	Spontaneous
3. Teachenor, 1923	Fracture	Mastoid	Spontaneous
4. Dandy, 1925	Fracture	Frontal	Operation
5. Dandy, 1925	Fracture	Mastoid	Spontaneous
6. Davidson, 192[illegible]	Fracture	Frontal	Spontaneous
7. [illegible]	Fracture	Frontal	Operation
8. [illegible]	Fracture	Mastoid	Spontaneous

The following is a summary of our case of traumatic pneumocephalus: C. D., a man, aged 37, Negro, was taken to the Indianapolis City Hospital, Aug. 19, 1930, following an accident in which he fell about 15 feet, striking the right side of the head.

Examination showed the patient to be in a semiconscious condition. Above the right ear was an abrasion of the scalp. There was a profuse bloody discharge from the right ear. This blood did not clot, suggesting a mixture with cerebrospinal fluid. The right pupil was larger than the left. The patient was too stuporous to answer questions but he could be made to move both arms and legs voluntarily. The pulse was 60, the blood pressure 92 systolic and 54 diastolic, and respiration 18. Marked emesis was present.

---

[1] Miller, S. W.; Klemmer, R. N., and Snoke, P. O.: Traumatic Pneumocephalus, Arch. Neurol. & Psychiat. 25: 903 (April) 1931.

The wound was cleaned and dressed. Sterile gauze was placed over the discharging ear, and 50 cc. of 50 per cent dextrose was given intravenously.

In twenty-four hours his state of semiconsciousness persisted. He still vomited frequently. The corneal reflex was absent on the right side and both the orbicularis oculi and levator palpebrae superioris of the same side were paralytic, together with the muscles of expression, indicating injury to the third, fifth and seventh cranial nerves on the right. The amount of drainage from the right ear canal continued the same but its character changed to a serosanguineous type.

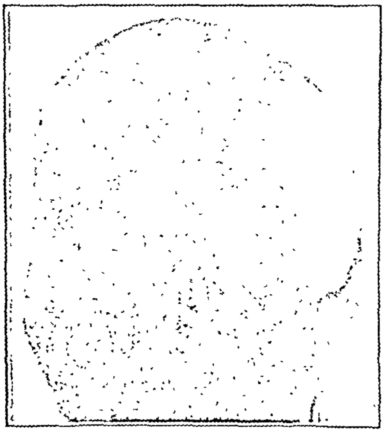

Fig. 1.—Anteroposterior view showing air in cerebral ventricles and subarachnoidal space.

On the third day roentgenograms of the skull disclosed a linear fracture in the right temporal area extending downward into the midportion of the mastoid portion of the temporal bone. The right ventricle was filled with air and there was also air over the surface of the brain in the anterior portion of the right frontal area. Up until this time there had been a copious discharge of blood stained cerebrospinal fluid from the right ear. On the fourth day this discharge stopped. The patient's general condition, however, remained the same. A lumbar puncture was then done which showed a pressure of 15 mm. of mercury with blood tinged cerebrospinal fluid. Eight cubic centimeters of this fluid was withdrawn until the manometer read 7 mm. of mercury. This procedure was repeated every forty-eight hours and after three punctures the patient's consciousness was restored and the pulse rate returned to normal.

We do not consider it wise to do a lumbar puncture in head injuries when there is a leakage of cerebrospinal fluid through a compound fracture of the skull, as there is some danger of so reducing the cerebrospinal pressure that there might be an aspiration of infected material at the site of fracture. In this case when the drainage from the meatus ceased we felt that the puncture was safe and, in fact, indicated.

The patient was discharged on the twentieth day, walking with a slightly spastic gait, with all tendon reflexes exaggerated, complete paralysis of the muscles of expression on the right side, partial loss of hearing in the right ear, partial paralysis of the right orbicularis oculi and levator muscle of the upper lid, partial paralysis of all extra-ocular muscles of the right eye except the superior oblique and the lateral rectus, and paresis of the muscles of mastication on the right side. There was effort cephalalgia of severe degree.

The patient returned to work in December, 1930, practically free from all symptoms except slight disturbance in gait and right facial paralysis.

When last examined, in September, 1931, the patient stated that he had continued to work, without headache, facial disturbance or diplopia, but that marked deafness in the right ear persisted. At times he complained of stiffness in his legs. Examination showed increased knee jerks but was otherwise negative. Right facial paralysis was almost entirely cleared up, so that it was not noticeable except on careful examination.

This case may be summarized as one demonstrating traumatic pneumocephalus in which the air was admitted to the subarachnoid space through simple fracture of the mastoid air cells and thence to the right ventricle by way of the foramina of Luschka and Magendie. Whether or not the pneumocephalus was a causative factor in the symptoms will remain in the realm of conjecture because the amount of cerebral concussion was sufficient to cause all the functional disturbance and clinical symptoms in this man.

COMMENT

Air may be introduced within the cranial cavity, concurrently with head injuries, by compound fractures of the skull with laceration of the dura mater, by deep perforating wounds of the gun-shot type, and by simple fractures involving the cranial air sinuses. Rarely gas-producing organisms may be the source of intracranial air in an infected wound which has perforated the skull. The air may occupy the subarachnoid space, the subdural space, the brain or the ventricles, and Dandy, in reviewing twenty-eight cases, cites fractures which render air passage from the mastoid cells and paranasal sinuses into the aforementioned spaces as the most frequent cause.

The mechanism of this phenomenon, in the presence of a trans-sinus fracture, is one of two types: suction of air replacing overflow of cerebrospinal fluid as in the example of an inverted narrow-necked bottle which contains fluid; or the sudden increase of air pressure within an air sinus at the moment of coughing or sneezing over the prevailing intracranial pressure. In addition to either of these mechanisms, the ball valve action of a bone fragment, tissue flap or possible foreign body may aid in the retention of air within the cranium. Thus it may be seen that air may pass through the fracture line intermittently as long as an avenue exists and buoyancy admits it to any part of the subarachnoid space and ventricular system. Humes has demonstrated that from fourteen to twenty-one days' time is required for the absorption of air filling the ventricles in artificial pneumocephalus; hence it is readily understood how air may persist in the ventricles for months after a fracture, as reported in some cases, in which the volume rate of introduction exceeds that of absorption.

Pneumocephalus occurring at the time of a severe head injury is merely an unusual clinical phenomenon, any possible symptoms being superseded by those of concussion, as was true in our case. However, if any of the classic signs of increased intracranial pressure persist, after any possible temporary brain trauma has subsided, otorrhea or rhinorrhea with sneezing is sufficient to make a diagnosis of pneumocephalus. Roentgenologic examination should confirm the diagnosis.

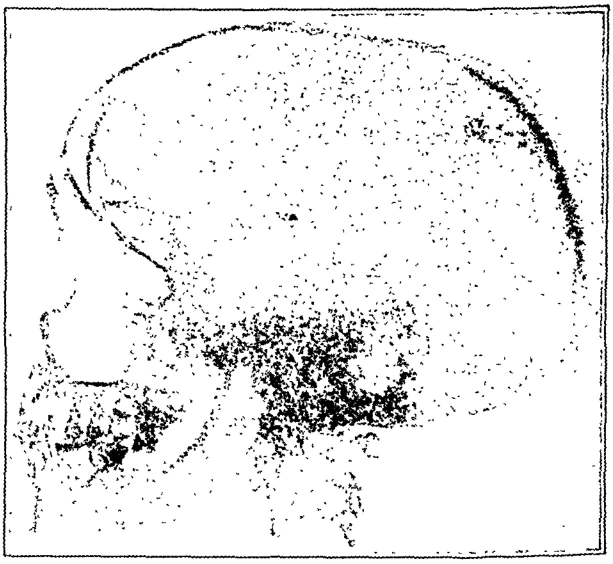

Fig. 2.—Lateral view showing the same and in addition a linear fracture of the temporal bone.

The prognosis in pneumocephalus of traumatic type on the whole is good. It may be noted with interest that intracranial infection complicating a cerebrospinal fistula occurred in only 25 per cent of the reported cases. Spontaneous closure of the draining sinus is accomplished in the majority of cases, and the intracranial air is absorbed by natural processes.

The successful treatment of those cases of pneumocephalus with a cerebrospinal fistula which does not heal spontaneously depends on surgical closure of the tract. Dandy[2] reports the use of fascia lata for the closure of a dural sinus in the frontal area. Surgical closure should be obtained as soon as the diagnosis is made; time spent in waiting for spontaneous healing is needless procrastination, for such plastic operations carry little risk.

Council on Pharmacy and Chemistry

REPORTS OF THE COUNCIL

The Council has authorized publication of the following reports.
W. A. Puckner, Secretary.

IODOXYBENZOATES OMITTED FROM N. N. R.

The known action of iodoxybenzoates led to clinical application of the drug in the treatment of arthritis by Young and Youmans.

In 1926 the Council reported on the clinical work of Young and Youmans, stating that a selected number of clinicians had been supplied with *o*-iodoxybenzoic acid prepared under the supervision of Young and Youmans for controlled hospital trials, and that the A. M. A. Chemical Laboratory was carrying out a chemical study with the intention of elaborating tests and standards which would insure a satisfactory supply of salts of *o*-iodoxybenzoic acid.

In consideration of the further reports by Young and Youmans and confirmatory evidence by others, the Council in 1927 admitted ammonium *o*-iodoxybenzoate with the standards elaborated by the A. M. A Chemical Laboratory to New and Nonofficial Remedies under the nonproprietary name amiodoxyl benzoate and admitted the product of the Abbott Laboratories, which had been found to meet the adopted standards, as Amiodoxyl Benzoate-Abbott.

Confirmatory reports, however, failed to establish the usefulness of the drug and in 1930 the Council decided to omit the drug from New and Nonofficial Remedies unless new and favorable evidence became available. Such evidence had not become available with the close of 1931 and, accordingly, the Council directed omission of the article Iodoxybenzoates and of amiodoxyl benzoate with the accepted brand Amiodoxyl Benzoate-Abbott.

SQUIBB ADEX TABLETS 10 D NOT ACCEPTABLE FOR N. N. R.

E. R. Squibb & Sons requested recognition of the name Squibb Adex Tablets 10 D for a cod liver oil concentrate fortified by addition of viosterol. The firm stated: "In our work on the development of the cod liver oil concentrate tablet which has heretofore been sold under the name of 'Adex,' we have developed a wholly new and novel preparation, the active therapeutic ingredients of which are vitamins A and D in exceptionally high concentration, and so compounded as to preserve the concentration unimpaired for years. This new tablet is not a mere concentration of cod liver oil. The vitamin A in the tablet and a part of its vitamin D are obtained by concentrating cod liver oil, but the remainder of the vitamin D in the new tablet is irradiated ergosterol." In regard to the stability of these tablets, the firm wrote: "By actual test the vitamin content of these tablets is known to be stable with no detectable deterioration either of vitamin A or D over a period of more than thirty-four months, the time thus far elapsed since our stability tests started. There are four reasons for this remarkable concentration and stability. 1. A special manufacturing process is used which protects the vitamins throughout the entire time or processing. 2. An ingredient is added which acts as an active protection against deterioration of the vitamins, particularly vitamin A. 3. A specially devised coating is applied under controlled conditions which further guards against loss of vitamin potency, and 4, the tablets are packaged under carbon dioxide. Some of these steps are protected by patent application and others are not of a nature capable of such protection. If the Council desires this information in greater detail, we will supply it. So far as we are informed, no other tablet receives this unique treatment looking toward the preservation against deterioration of its labile-active ingredients."

The Council has repeatedly called attention to the fundamental importance of its rule designed to prevent the multiplication of names for the same product. This rule provides that the discoverer of a new product or of a new and sufficiently important therapeutic use for an old product may give it an arbitrary name. Squibb & Sons are not the first to prepare a cod liver oil concentrate nor does the addition of viosterol to a cod liver oil concentrate present a discovery. While Squibb & Sons deserve credit for the efforts which they have made toward increasing the potency and stability of cod liver oil concentrates, other firms which are engaged in the marketing of such products have worked in the same direction.

The Council considered the arguments advanced by Squibb & Sons in favor of the recognition of their proprietary name for their cod liver oil concentrate with viosterol and decided that in conformity with its rules governing the recognition of proprietary names, it cannot recognize the name Squibb Adex Tablets 10 D because the application of a proprietary name to this product is not in the interest of the medical profession or the public and declared Squibb Adex Tablets 10 D unacceptable for New and Nonofficial Remedies.

Committee on Foods

The following products have been accepted by the Committee on Foods of the American Medical Association following any necessary corrections of the labels and advertising to conform to the Rules and Regulations. These products are approved for advertising in the publications of the American Medical Association, and for general promulgation to the public. They will be included in the Book of Accepted Foods to be published by the American Medical Association.
Raymond Hertwig, Secretary.

BUTTER CREAM BREAD

Manufacturer.—Anchor Bread Company, Sacramento, Calif.

Description.—A white bread made by the sponge dough method.

Manufacture.—The sponge dough ingredients, patent flours of Western and Northwestern wheats, water, salt, yeast and a yeast food containing calcium sulphate, ammonium chloride, sodium chloride and potassium bromate, are mixed in a high speed mixer. The sponge dough is fermented for from four to five hours, after which are added flour, water, salt, sucrose, butter and cream to make the completed dough, which is cut into pieces of desired weight. The pieces are fermented for a short time, molded into loaf form, panned, further fermented, baked for from thirty to thirty-five minutes, cooled, and wrapped in wax-paper.

The factory, equipment and storage rooms for the materials used are kept in strictly sanitary condition.

Analysis (submitted by manufacturer).—

	per ounce
Moisture (entire loaf)	35.5
Ash	0.8
Fat (ether extraction method)	2.5
Protein (N × 6.25)	9.6
Crude fiber	0.2
Carbohydrates other than crude fiber (by difference)	51.4

Calories.—2.7 per gram; 77 per ounce.

Claims of Manufacturer.—A bread of good quality.

VINCENNES "CLASS A" BRAND TOMATO JUICE AND VINCO TOMATO JUICE

Manufacturer.—Vincennes Packing Corporation, Vincennes, Ind.

Description.—Pasteurized tomato juice with added salt; retains in high degree the vitamin content of the raw juice.

Manufacture, Chemical Analysis, Calories, Micro-Organisms, Vitamins, Claims of Manufacturer.—See these sections for Alice of Old Vincennes Tomato Juice (The Journal, Feb. 20, 1932, p. 640).

RADIOLOGIC SERVICE IN THE UNITED STATES

REPORT BY THE COUNCIL ON MEDICAL EDUCATION AND HOSPITALS

The work of preparing a list of acceptable "radiologic laboratories and departments of radiology" was assigned to the Council on Medical Education and Hospitals by the House of Delegates at the Minneapolis session in 1928. The "Essentials" were prepared by the Council in collaboration with a large number of specialists in the field of radiology. Suitable questionnaires were prepared in the same manner and were mailed to all the physicians who were known to be engaged in the practice of radiology and roentgenology. The majority of the physicians so engaged returned their questionnaires and they were considered for the list. To assist the Council in preparing the list, the officials of the two leading radiologic societies cooperated with the Council's special committee by appointing qualified radiologists in all parts of the country to act as advisers. These advisers, numbering 198, examined the credentials of applicants from their respective localities, made inspections, and advised which candidates could qualify, according to the "Essentials." The resulting tentative list, together with a detailed report on the survey, was published in the Radiologic Number of The Journal, May 23, 1931.

Since various branches of medicine look to the radiologist for important aid in diagnosis and treatment, the careful certification of physicians qualified in radiology should be made to protect the patient and the profession. A powerful influence in the regulation of those qualified is, of course, membership in special radiologic societies. This membership immediately bars the lay practitioner and, to some extent, the physician who has not had adequate training and experience. Membership lists of the special societies include the names of many whose main interest lies in other specialties.

The Council has understood from the beginning and has advocated the principle that the practice of radiology is the practice of medicine. It has followed this principle in the interpretation of the essentials, in the preparation of its lists and in every opportunity that the Council has had to express itself on this point to the entire medical profession.

EMPHASIS PLACED ON SPECIALISTS

At first the emphasis was on laboratories and departments of radiology and roentgenology. Both the questionnaire and the "Essentials" laid stress on the laboratories, including equipment, personnel, records and publicity. The tentative list referred to laboratories or departments of radiology and roentgenology. But difficulties were found in the listing of laboratories as such, because laboratories change names; they also change directors and ownership, these changes often resulting in an entire change of methods and sometimes a reversal of ethical principles. It became apparent that the determining factor in radiologic service is the specialist who does the work or supervises it. Emphasis, therefore, was shifted from the laboratory to the directing radiologist, the main emphasis now being placed on his qualifications.

The "Essentials" have been recently revised to correspond with this new point of view, and the newly revised "Essentials," as adopted by the Council at its meeting in February, 1932, are printed in connection with this article.

HOW THE LIST IS COMPILED

The routine by which all applicants are admitted to the list is as follows:

1. A questionnaire is sent to all specialists in the field who, according to information, seem to have the necessary qualifications.
2. On receipt of the returned questionnaire, the record and credentials of the applicant are verified in the biographic file of the American Medical Association.
3. Each application is submitted to at least three or more advisers, who give their estimate and opinion of the qualifications of the applicant, based on personal knowledge or inspection, or both.
4. Membership in special societies is looked up, and the advice of the officers of those societies and the officers of county medical societies, and of councilors, is obtained.

In this way the principle is observed that specialists should be judged by specialists. Those who work and associate with specialists have the best opportunity of knowing them. Due attention is also given to the records in the biographic file of the American Medical Association and to the individual's own report on himself and his work.

The first survey covered mainly those radiologists who were conducting laboratories of their own and included, also, those that were connected with hospitals, but did not include others, such as those who teach and supervise radiologic work in medical schools and those working in research institutions and government departments. More recently, the work has been extended to all of these fields. Questionnaires have recently been sent out and applications received from thirty-two of these specialists who were not included in the first survey. There has not been time to give to all the later applications the consideration that is due them, which will explain the omission of some from the list contained in the accompanying pages.

Additions and revisions will be made from time to time; suggestions for changes will be received and consideration of new applications will go on continuously. Cooperation by the men in the specialty has been excellent and must continue in order that the work may be of optimum value.

PATHOLOGISTS AND CLINICAL PATHOLOGISTS

The list of clinical pathologists which accompanied the list of radiologists in the Radiologic Number for May 23, 1931, is not included in the present issue but is being revised for a later issue of The Journal. This will give the necessary time for a thorough revision of that list, including a classification of pathologists and clinical pathologists so as to form a more accurate and a more useful list. Also, the pathologists and clinical pathologists connected with medical colleges, research institutions and government departments will be included, as is being done in the case of the radiologists.

ESSENTIALS FOR ADMISSION TO LIST OF PHYSICIANS SPECIALIZING IN RADIOLOGY

Physicians Eligible

Consideration for admission to the list is open to all regular licensed physicians engaged in radiologic work in accordance with the essentials, whether connected with a hospital or conducting an independent laboratory.

1. Qualifications

(*a*) The candidate shall be a graduate of a medical school that is approved by the Council on Medical Education and Hospitals and shall be licensed to practice medicine in the state in which his department is located. He shall also have had special training, such as is approved by the Council, in radiology, roentgenology or radium therapy at an acceptable school—preceptorship, hospital or clinic, department of radiology, roentgenology or radium therapy—for a period of at least three years, or, in lieu of such training, shall have had a minimum of five years' experience in the exclusive practice of radiology, roentgenology or radium therapy. He must be a man of good standing in the medical profession, and particularly among those specializing in radiology. He shall either be on a full time basis or have definite hours of attendance at the department, such hours to be ample to insure the element of medical consultation in every examination or treatment.

(*b*) The department shall be under the direction of a physician radiologist, roentgenologist or radium therapist, as the circumstances may require. The director shall be responsible for all examinations and treatments. He shall be responsible for all professional assistants and for the efficient maintenance of the department.

Physicians employed by laboratories which are under lay control and direction will not be eligible for consideration for this listing.

(*c*) *Assistants.*—The director may have a corps of qualified medical and technical assistants responsible to him, and for whom he is responsible, to carry out accurately the various functions of the department.

2. Definitions

Radiology.—The branch of medicine which deals with the diagnostic and therapeutic application of radiant energy, including roentgen rays, radium, ultraviolet rays and other spectral radiation.

Department of Radiology.—A private laboratory or department of a hospital, clinic or other institution, organized and equipped for the diagnostic and therapeutic application of radiant energy, including roentgen rays, radium, ultraviolet rays and other spectral radiation.

Radiologist.—A qualified physician who also has obtained adequate special training and experience in general radiology.

Roentgenology.—The phase of radiology which deals with the diagnostic and therapeutic application of roentgen rays only.

Department of Roentgenology.—A private laboratory or department of a hospital, clinic or other institution organized and equipped for the diagnostic and therapeutic application of roentgen rays only. A department organized and equipped solely for the diagnostic or therapeutic application of roentgen rays shall be known as a department of diagnostic or therapeutic roentgenology, respectively.

Roentgenologist.—A qualified physician who has had adequate training and experience in the diagnostic and therapeutic application of roentgen rays.

Diagnostic Roentgenologist.—A roentgenologist who limits his practice to the diagnostic phase of roentgenology.

Therapeutic Roentgenologist.—A roentgenologist who limits his practice to the therapeutic phase of roentgenology.

Radium Specialist.—A physician who has had adequate training and experience in the therapeutic use of radium and who specializes in this work.

3. Scope

A department of radiology should be able to render all of the following services:

(*a*) Roentgenography, simple or stereoscopic, of any part of the body, with medical interpretation of the roentgenographic observations, and under satisfactory conditions for the protection of the patient and of the professional and technical personnel.

(*b*) Roentgenoscopy of any part of the body, in any position, with or without opaque mediums, with medical interpretation of the roentgenoscopic observations, and under satisfactory conditions for the protection of the patient and the professional and technical personnel.

(*c*) Roentgenotherapy of all benign and malignant diseases amenable to such treatment with roentgen rays generated at low, moderate or high voltage (long, medium or short wavelength), as the conditions may require, and under satisfactory conditions for the protection of the patient and of the professional and technical personnel.

(*d*) Radium therapy of all benign and malignant diseases amenable to such treatment with an adequate quantity of radium element or emanation, and under satisfactory conditions for the protection of the patient and of the professional and technical personnel.

Ultraviolet therapy, general or local, with satisfactory air-cooled and water-cooled quartz mercury lamps or carbon arc lamps, with suitable quartz and other applicators for irradiation of cavities, sinuses or the superficial lesions under pressure, and under satisfactory conditions for the protection of the patient and of the professional or technical personnel. This stipulation is not mandatory, but the Council recommends that every department of radiology be equipped for ultraviolet therapy or that the ultraviolet equipment of hospitals be placed in the department of radiology. Ultraviolet treatment by the department of physical therapy shall not be countenanced unless such department is under the control and supervision of a medical director who has specialized in radiology.

A department of roentgenology should be able to render the services specified under *a, b* and *c*.

A department of diagnostic roentgenology should be able to render the services specified under *a* and *b*.

A department of therapeutic roentgenology should be able to render the services specified under *c*.

A department of radium therapy should be able to render the services specified in *d*.

4. Housing

The housing should be adequate for the proper functioning of the department of radiology or roentgenology. Damp or ill ventilated quarters are unsuitable for such work.

5. Equipment

The equipment should be sufficient to carry out properly the technical procedures and activities of the department of radiology, roentgenology or radium therapy.

6. Protection

The arrangement of working rooms and conditions, and the construction of all apparatus shall be such as to provide adequate protection, both from electrical shock and from avoidable exposure to roentgen rays or radium, to patients, attendants and other persons in or near the department. The requirements in this respect are based on the recommendations adopted by the International Congress of Radiology, held at Stockholm, Sweden, in July, 1928, and approved by the American Roentgen Ray Society and the Radiological Society of North America.

7. Records

Full records of all examinations and treatments made by the department, suitably indexed, are essential. Roentgenograms made in the department should have inerasible identification marks which will preclude error as to patients concerned. Roentgenograms may be lent to referring physicians but should be returned to the laboratory for filing and future reference. Suitable storage facilities should be provided where roentgenograms and other records will be both safe and readily available for reference. They shall be kept as long as there is the possibility of their being needed for the benefit of the patients or their physicians.

As roentgenography constitutes only a kind of medical examination, on which the roentgenologist's opinion of the patient's condition is partly or wholly based, and as the opinion of the specialist is the essential factor, the Council holds that the introduction of roentgenograms as evidence in medicolegal cases should be discouraged as immaterial and as tending to adulterate the process of justice. There is no more reason for the introduction of roentgenograms than for requiring a pathologist to bring to court his microscope and his sections of tissues.

8. Reports

The reports of a department of radiology, roentgenology or radium therapy shall be made through the director on stationery or blanks having the name of the director printed thereon. Under no circumstances shall roentgenologic diagnoses, interpretations, opinions, statements of prognosis, or therapeutic suggestions be offered by the nonmedical personnel.

9. Library

The department of radiology, roentgenology or radium therapy should be provided with, or have convenient access to, a library including current scientific books and journals on all the various subjects required in its work.

10. Ethics, Fees and Publicity

Radiology is a special type of medical practice, and the physician practicing radiology is subject to the same rules of special training and conduct that govern his fellow specialists in the practice of medicine and surgery. The Principles of Medical Ethics of the American Medical Association shall apply in all cases. The fees charged for radiologic services shall be under the control of the director of the department. All systems of rebates, discounts, special group rates, etc., shall be considered unethical, except that, where the patient's economic status is the determining factor, the radiologist, like his fellow physician in medicine or surgery, may waive part or all of the fee.

The publicity of a department of radiology, roentgenology or radium therapy should be in professional good taste and limited to statements of fact as to name, address and telephone number; names and titles of the director and other active responsible personnel; field of work covered, office hours, directions for referring patients, and so forth. It should not contain misleading statements or claims of unusual superiority. It should not advocate medical fads nor lay undue stress on the importance of roentgenologic observations. On the letterheads or any other form of publicity, only the names of those rendering regular services to the department should appear as being connected with the department. Advertising matter should be directed only to physicians, either through bulletins or through recognized technical journals, and never to the nonprofessional public, as, for example, by announcements in popular journals and periodicals, circulars, pamphlets or telephone lists.

11. Admission to the Approved List

Only when the physician is the director or is affiliated with a department of radiology, roentgenology or radium therapy in which the personnel, space, equipment, management, finances and records are such as will insure honest, efficient and accurate work may he expect to be listed. Physicians desiring to be considered for the approved list should apply to the Council on Medical Education and Hospitals of the American Medical Association, 535 North Dearborn Street, Chicago.

PHYSICIANS SPECIALIZING IN RADIOLOGY—1,003

The list contains the names of only those who responded to the questionnaire, who have been found to comply with the "Essentials," and who were recommended by the advisers for their respective states. Those who are still under consideration, and others who may apply, will, when accepted, be added in subsequent issues of The Journal.

The type of service rendered is given opposite the name. "Radiology," under "Type of Service," always includes short wave therapy, also known as "deep therapy." The asterisk (*) on "roentgenology" indicates that short wave therapy is included.

THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION

535 North Dearborn Street - - - Chicago, Ill.

Cable Address - - - - "Medic, Chicago"

Subscription price - - - - - Seven dollars per annum in advance

Please send in promptly notice of change of address, giving both old and new; always state whether the change is temporary or permanent. Such notice should mention all journals received from this office. Important information regarding contributions will be found on second advertising page following reading matter.

SATURDAY, MARCH 19, 1932

DEATHS OF PHYSICIANS PUBLISHED IN 1931

During 1931, the deaths of 2,952 physicians of the United States were recorded in The Journal as compared with 2,943 during 1930 and 2,797 during 1929. The list includes one who died in the Philippine Islands, one in Porto Rico, three in China, two in India and one each in France, South America, Central America, Mexico, Norway and Sweden. The total number published was 3,074, which includes 122 Canadians. In 1931 the obituaries of 84 women physicians were published, as compared with 80 in 1930. Twenty-six Negro physicians died during the year. The graduates of medical schools in the United States for the fiscal year ended June 30, 1931, numbered 4,735. Deducting the number of physicians whose obituaries were published, there was a net addition to the ranks of the profession for the year of 1,783, which, figured thus, is an increase of 161 over 1930.

Ages.—The average age at death of those classified as of the United States was 63.8, as compared with 63.7 for 1930. Two physicians were 99 years old and thirty lived to be 90 or more. One was 23 years old and two were 24. Twenty physicians died between the ages of 25 and 29, 51 died between 30 and 34, 66 between 35 and 39, 86 between 40 and 44, 169 between 45 and 49, 285 between 50 and 54, 360 between 55 and 59, 426 between 60 and 64, 428 between 65 and 69, 420 between 70 and 74, 296 between 75 and 79, 202 between 80 and 84, and 140 at or above 85. March was the month of most deaths, with 292.

Accidental Deaths.—There were 139 physicians who died as a result of accidents in 1931, compared with 130 in the previous year. Automobile accidents accounted for seventy-one, five more than in 1930. In 1931, deaths from falls numbered twenty-two, the second largest number among those due to accidental causes. Eleven deaths were caused by drowning, seven by airplane accidents, six by gunshot wounds, three each by illuminating gas and carbon monoxide, and two from overdoses of medicine. The remaining accidental deaths resulted from the following causes; burns, phosphorus, carbon tetrachloride and alcoholic poisoning, earthquake, explosion, anesthetic, cut by glass, head caught in drawer of wardrobe trunk, collision of horse and buggy with train, burns from x-ray machine, crushed by automatic elevator, baked in electric cabinet; cut while shaving, collapse of concrete pillar, and street car accident.

Suicides and Homicides.—Sixty-four physicians committed suicide in 1931, two less than in 1930. The method most frequently employed was shooting, which accounted for thirty-four deaths. Poison was used in five cases, hanging in four, incised wounds four, drugs and gas three each, carbolic acid, drowning, anesthesia and strangulation one each, and in the remaining cases the method was not reported. There were nine homicides caused by shooting and one by stabbing.

Causes of Deaths.—Heart disease was again the leading cause of death, with 1,065 deaths compared with 1,059 for 1930. Some contributory causes are included in the tabulation, as they have been in former years. A report that the cause of death was "chronic nephritis and heart disease," for example, is so published in The Journal and is reported on the statistical charts under both diseases. Of the deaths from heart disease, endocarditis or myocarditis was specified in 342, angina pectoris in 114 and pericarditis in 7. Cerebral hemorrhage was the second most frequent cause reported, with 365 deaths; 25 additional deaths were reported as due to paralysis. Pneumonia was the third most frequent cause; lobar pneumonia was reported in 254 cases and bronchopneumonia in 58. Fourth on the list was arteriosclerosis, with 252 deaths. Nephritis caused 237 deaths, of which 18 were specified as acute nephritis. Of the 236 deaths caused by cancer, the stomach and liver were affected in 63 cases, the intestine in 29, the prostate gland in 24, the buccal cavity in 12, and in 108 the part affected was not specified. Embolism and thrombosis caused 104 deaths; uremia, 80; tuberculosis, 65; diabetes mellitus, 64; septicemia, 45; appendicitis and typhlitis, 43; intestinal obstruction, 22, and other diseases of the digestive system, 38; diseases of the prostate, 40, and other diseases of the genito-urinary system, 25; influenza, 36, and other diseases of the respiratory system, 40; senility, 36; cirrhosis of the liver, 26; hypertension, 24; peritonitis, 23; ulcer of the stomach, 21, and other diseases of the stomach, 6. Conditions that caused a few deaths each are as follows: cholecystitis, 18; pernicious anemia, and diseases of the bones and organs of locomotion, 16 each; encephalitis, 15; biliary calculi and gangrene, 14 each; leukemia, 13; meningitis and sarcoma, 11 each; chronic bronchitis and asthma, 9 each; erysipelas, 8; dementia paralytica, 8; other diseases of the nervous system, 7; diseases of the liver, agranulocytic angina and paralysis agitans, 6 each; carbuncle and diseases of the veins, 5 each; diseases of the circulatory system, pleurisy, acute articular rheumatism and aneurysm, 4 each; alcoholism, hernia, Hodgkin's disease, sinusitis and agranulocytosis, 3 each; tetanus, tumors, shock, heat prostration, septic sore throat, diseases of the spinal cord and diseases of the artery, 2 each. The following list of causes was given for one case each: general diseases, locomotor ataxia, diseases of organs of hearing, diseases of skin or cellular system, scarlet fever, pancreatitis, chorea, anthrax, hemorrhagic purpura, Banti's disease, psittacosis, lymphosarcoma, splenic anemia, insanity, hiccups, Friedreich's ataxia, pellagra, episiotomy, brain abscess, sunstroke, undulant fever, encephalomalacia, adenoma of the pituitary gland, adenoma of the prostate, epilepsy, poliomyelitis, acute abscess, secondary anemia, hypernephroma and brain tumor.

Positions.—Among the decedents were 159 who were or had been teachers in medical schools, 223 who served in the World War, 56 veterans of the Civil War and 42 veterans of the Spanish-American War. Eighty-two had been health officers; 81, members of boards of education, and 70, members of boards of health. There were 46 coroners, 43 mayors of municipalities, 42 members of state legislatures, 14 members of the state boards of medical examiners, 14 members of the U. S. Army Medical Corps and 9 of the U. S. Naval Medical Corps. Twenty-five authors, 20 bank presidents, 16 druggists, 11 members of city councils, 9 editors, 7 missionaries, 6 postmasters, 4 dentists, 4 justices of the peace, 2 lawyers, 1 clergyman, and 1 police surgeon were also included.

Association Officers.—The obituaries published in 1931 of former officers of the American Medical Association included two vice presidents, two trustees, fifteen members of the House of Delegates, ten section officers and one member of a council. Thirty-five presidents of state societies died during the year, and five secretaries.

"FREE" AND "BOUND" WATER IN COMPENSATION FOR LOSS OF BLOOD

A survey of the composition of body fluids and tissues emphasizes the large relative proportion accounted for by water. The digestive fluids contain only about 1 per cent of total solids; even bladder bile, after the usual desiccation, is four-fifths water. Of the skeletal muscle, only 25 per cent is solids; even fresh bone will lose two fifths of its weight when heated to constant weight. The enamel of the teeth, the hardest tissue of the body, contains 5 per cent of water. In spite of the ubiquitous distribution of water, it is safe to say that pure water does not exist as such in the organism. In it are dissolved a great variety of substances, ranging from typical inorganic crystalloids such as sodium chloride at one extreme to colloidal solutes such as the proteins at the other. When a piece of tissue is rapidly frozen at a low temperature and an estimate made of the quantity of water present in the form of ice, it is usually found that this amount of moisture is less than that determined by heating to constant weight. Observations of this nature have led to the conclusion that part of the water in tissues and body fluids is "free," whereas the rest is "bound" more tenaciously to the colloids either in solution or in contact with it and is therefore more difficult to release.

The appreciation of the physical importance of fluid volume in maintaining physiologic equilibriums has prompted an examination of the relative parts played by "free" and "bound" water in certain pathologic conditions. In a recent investigation, Robinson and Parsons[1] followed the changes in water content of blood and muscle under various experimental conditions analogous to shock. After a moderately severe hemorrhage the usually observed compensation for loss of volume occurs by a passage of water from the tissues, especially the muscles, to the blood. The replacement of erythrocytes and hemoglobin is delayed for a considerable time. While both the total and the "free" water of the blood was augmented, the restoration of the plasma volume was largely due to increase in "free" water; the muscles lost both "free" and "bound" water, though in one experiment the compensation for lost blood was made principally at the expense of the "free" water of the muscle. After trauma to an extremity there was a shift in water. Moderate injury caused a decrease in "free" water in the blood with little change in "bound" water; if the trauma was severe enough to produce hemorrhage there was the typical posthemorrhagic dilution of the blood caused largely by increase in the "free" water, accompanied by a loss of free water from the uninjured muscles. After the injection of histamine, the blood became more concentrated as the result of a loss of "free" water and the muscle gained water at about the same rate. In one experimental animal, a spontaneous fall of blood pressure occurred with a decrease in water of the blood and a concomitant gain in muscle water. In both instances the changes were accounted for entirely by the shift in "free" water.

Extensive studies by Blalock and his co-workers[2] have demonstrated that the fall in blood pressure following trauma in the viscera, injury to the extremities and severe burns can be accounted for in large part by the passage of water from the blood to the injured areas. The observations of Robinson and Parsons show not only that uninjured tissue gives up water to the blood under such circumstances but also that this readily available fluid arises principally from the "free" water component of the muscle. The cooperation of uninjured tissue in restoring fluid volume to the blood after extensive hemorrhage either to the outside or into damaged tissue is a striking example of compensation in the organism. The studies have shown the notable mobility of part of the tissue water; on the other hand, water bound to protoplasmic colloids or concerned in the maintenance of essential physicochemical equilibriums involving colloidal solutes tends to be more stable and less responsive to the emergency demands of the organism as a whole.

ABSORPTION THROUGH SINUS MUCOSA

Although the fundamental reactions and activities of all living cells are essentially alike, the mechanisms devised by nature to suit the exigencies of differentiation are varied. With the multiplication of cells constituting the organism the simple devices for digestion, absorption and respiration which satisfied the single-celled individual have been modified not so much in character as in allocation to specialized tissues. Differentiation has resulted in localization of these functions. Some of the most interesting of these adaptations center about the gastro-intestinal tract and its natural diverticula. In the mouth, stomach and intestine food is changed by chemical and mechanical means to soluble forms. But in this state of transformation it is still outside the body. Fundamentally, therefore, the phenomenon of absorption is of utmost importance in the life of the organism. In the gastro-intestinal tract proper this function is most highly developed in the small and large intestine, neither the mouth and esophagus nor the stomach being seriously considered as absorptive organs for the usual food materials in the light of the best experimental evidence. The epithelium in the lungs is extraordinarily efficient in allowing the passage of respiratory gases and it has been shown that the mucous membrane of the mouth also permits the diffusion of these gases.[1] There are occasions when it is desired to use drugs in certain of the evaginations of the alimentary canal specifically for their local influence; under these conditions the possibility of absorption into the systemic circulation becomes of considerable importance.

An investigation of the absorption from sinus mucosa has recently been reported by Childrey and Essex.[2] Various drugs and toxins were introduced into the frontal sinus of experimental animals under general anesthesia and absorption was detected by observing either the blood pressure or the appearance of the appropriate material in blood and urine depending on the substance used. The effect produced by subcutaneous or intravenous injections of the substance served as a check on the absorption through the sinus mucosa. Five times the dose of histamine giving a distinct depressor response after intravenous and subcutaneous administration gave negative results when injected into the nasal cavity and into the sinus. Four times the effective subcutaneous dose of nicotine failed to induce a positive reaction on the blood pressure when given in the sinus. Negative results were likewise recorded after injections of ephedrine and of epinephrine into the frontal sinus. Rattlesnake venom (crotalin) was then used, the criterion of its appearance in the circulation being a fall in blood pressure and an increase in red cell volume after subcutaneous injection. When this substance was placed in the frontal sinus, the blood pressure change was insignificant though there did occur a swelling of the erythrocytes. Phenolsulphonphthalein injected into the nasal mucosa showed a markedly delayed absorption and excretion compared to that after subcutaneous injection. The absorption from an infected sinus, however, was prompt though of abnormally long duration.

It is apparent that absorption of drugs and certain therapeutic agents from the nasal sinus and nasal cavity either does not occur or exhibits a low degree of efficiency. This is in marked contrast to some of the typical absorbing membranes elsewhere in the body. The experimental evidence leads to the conclusion that highly toxic substances may be used in the treatment of sinus disease without great danger of absorption. Again the slow absorption through sinus mucosa even when inflammatory changes have occurred permits the conclusion that bacterial toxins from infected sinuses are likewise absorbed with difficulty. Presumably these results are to be associated primarily with normal intact mucous membrane. Controlled observations with infected and inflamed mucous membranes should be made with a variety of substances and of bacterial agencies.

Current Comment

LOSS OF WEIGHT IN THE NEW-BORN

The characteristic loss of weight of infants soon after birth—a process extending over a period of days—has been the subject of much discussion and not a little clinical investigation by pediatricians. Those who contend that the characteristic phenomenon is "nature's way" and need not give the physician any undue concern argue that the alimentary tract of the new-born infant remains unable for some days to perform the essential digestive functions; hence it should be spared. Attempts to feed the infant in some special way during the period of weight loss have as a rule not been satisfactory. Mere loss of weight is not a formidable condition when one recalls the normal powers of recuperation that usually follow such recessions. But the relative inanition often brings about other consequences which later in life would certainly be considered pathologic. Thus there may be an "inanition temperature" during the period of greatest loss in weight—usually on the third or fourth day following birth. This has been ascribed to dehydration and lack of food. Icterus neonatorum also sometimes is an unwelcomed symptom. "Acidosis" often seems to be established. On this account Eder and Bakewell[1] of the Santa Barbara Clinic in California began the routine use of a carbohydrate (lactose) and a potential alkali (sodium citrate) in a large series of new-born infants. The California pediatricians announce that the addition of 5 grains of sodium citrate to each 2 ounces of 5 per cent lactose solution given to new-born infants during the first few days of life appears to be of value in decreasing the initial postnatal loss in weight. The average loss in 100 consecutive infants was 5.3 ounces, or 150 Gm. In comparison with untreated infants, weight at birth is regained earlier; 83 per cent had again reached their original weights on or before the fourteenth day. Only three infants had inanition temperature. The general condition of the infants as shown by activity, ability to nurse, color and absence of icterus neonatorum was far better than that of infants who had lactose solution without sodium citrate. Larger experience should indicate whether the proposed treatment is really worth while.

THE FAMILY PHYSICIAN AND THE TRUST OFFICER

In the administration of estates, problems develop that cannot be solved by bankers alone or by an order of the probate court. That the administrator may manage an estate to the best interest of the family of the deceased, the trust officer must have knowledge of each member of the family. Mr. John H. Boushall[1] of the First National Bank of Tampa, Fla., suggests that the trust officer will find the necessary cooperation through the family physician. No one other than the family physician can know better the lives and the physical set up of each member of the family. In the administration of an estate, the trust officer first has to consider the widow, who has been plunged into business affairs through the death of her husband and, at the same time, brought to the verge of prostration. With the guidance of the family physician who knows her family, the trust officer will secure her confidence and cooperation. Some of the children may have peculiarities that will give the trust officer more trouble than any other feature of his administration. Such children may insist on being humored or receiving special consideration or special allowances, all of which will tax the trust officer's patience as well as the funds of the estate. To the physician who has seen the children grow up, such peculiarities are no cause of alarm. His advice and the child's understanding that the physician knows him add weight to the trust officer's decisions. When an influential friend of the family suggests that one of the children should take a trip hither and yon in search of better health, the family physician will know that what is really needed is an adjustment of personal habits to a more sensible mode of living. A friend may suggest to the trust officer, furthermore, that the neurotic child should be placed under the care of some noted and probably distant medical expert, and that might prove to be more expensive than the estate could afford. Again, it can be shown to the trust officer that such treatment may be unnecessary, for the family physician is able to understand and to evaluate the opinions and methods of specialists. The patient in this case also will know that the family physician knows the truth. Through the entire administration of the estate, Mr. Boushall suggests, decisions affecting the well being of the widow and children can be happily worked out through cooperation of the trust officer and the family physician, between whom there naturally will be a spirit of mutual respect and understanding.

Association News

MEDICAL BROADCAST FOR THE WEEK

American Medical Association Health Talks

The American Medical Association broadcasts on Monday from 12 noon to 12:05 p. m. over Station WBBM (770 kilocycles, or 389.4 meters) and other stations of the Columbia Broadcasting System, and on Wednesday and Friday from 2:25 to 2:30 p. m. over Station WBBM, Chicago.

The program for the week is as follows:

March 21. Cancer Among Women.
March 23. Fifty Years Later.
March 25. Too Many Children Spoil the Foster House.

There is also a fifteen minute health talk sponsored by the Association on Saturday from 11:15 to 11:30 a. m., over Station WBBM, Chicago.

The program for the week is as follows:

March 26. The Sign on Your House (concluded).

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST: SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION, PUBLIC HEALTH, ETC.)

CALIFORNIA

State Board of Health Reorganized.—Drs. Junius B. Harris, Sacramento, and Gifford L. Sobey, Paso Robles, were recently appointed members of the California Department of Public Health to succeed Drs. Robert A. Peers, Colfax, and Fred F. Gundrum, Sacramento, whose terms expired. Drs. Peers and Gundrum have served continuously as members of the board since 1915. In the reorganization of the board, Dr. John H. Graves, San Francisco, succeeded Dr. George E. Ebright as president, and Dr. Edward M. Pallette, Los Angeles, became vice president. Dr. Ebright will continue as a member. Other members of the board, in addition to those mentioned, are Drs. William R. P. Clark, San Francisco, and Giles S. Porter, Los Angeles, who is director of the department. Dr. Harris is president of the California Medical Association.

Society News.—Dr. Henry D. Chapin, Bronxville, N. Y., gave a lecture at Stanford University School of Medicine, San Francisco, March 4, on "Social Aspects of Child Welfare." ——Dr. John C. Meakins, Montreal, Que., Canada, addressed the San Francisco County Medical Society, March 15, on "Treatment of Cardiac Irregularities."——An annual midwinter course in otolaryngology was instituted in Los Angeles, January 15; the guest lecturers for the first course included Drs. Georges Portmann, Bordeaux, France; Edmund P. Fowler, New York, and Harry L. Baum, Denver.——The Northern California Public Health Association, at its annual meeting in San Francisco, January 30, elected Dr. Thomas A. Storey, Stanford University, president, and Dr. Herbert F. True, city health officer, Sacramento, president-elect. Other officers were

---

[1] Eder, H. L., and Bakewell, Benjamin: Effect of Sodium Citrate on the Loss of Weight in the New-Born Infant, Am. J. Dis. Child. 42:1079 (Nov.) 1931.

[1] Boushall, J. H.: Doctors and Trust Officers, Am. Bankers A. J., January, 1932, p. 437.

Dr. Wilfred H. Kellogg, Berkeley, vice president; Dr. Walter H. Brown, Palo Alto, secretary, and Miss Mary E. Davis of the state department of public health, treasurer.——Dr. George Piness, Los Angeles, addressed the San Diego County Medical Society, March 8, on "Practical Application of Allergy in General Medicine."

Rules for Adoption of Children.—In an effort to avoid irregular methods used by superintendents of some maternity hospitals in the separation of infants from their mothers for adoption, the state board of health announces that the new adoption law requires:

1. That relinquishment for adoption must be signed by father or mother before subscribing witnesses and acknowledged before the agent of an organization licensed by the state department of social welfare.
2. A certified copy of the above relinquishment must be filed with the state department of social welfare, 111 State Building, San Francisco, within twenty-four hours.
3. Persons desiring to adopt a child may petition the superior court of the county in which they reside. Consent for adoption is required in all cases, except (*a*) in cases of adoption by step-parent in which one natural parent retains custody and control of child, and (*b*) in cases in which one of the agencies mentioned by the board joins in the petition for adoption.

The consent for adoption must be signed in the presence of an agent of the state department of social welfare on a form prescribed by that department.

COLORADO

Annual Clinics.—The University of Colorado School of Medicine and Hospitals will hold its annual clinics, March 23-25. The program calls for special teaching and diagnostic clinics in general surgery, pediatrics, otolaryngology, general medicine, urology, proctology, dermatology, tuberculosis, neurology, obstetrics and gynecology, orthopedics, ophthalmology and psychiatry. Dr. Leonard G. Rowntree, Rochester, Minn., will be the guest speaker, Thursday evening, March 24; his subject will be "Blood Pressure States."

Society News.—Dr. Maurice H. Rees, Denver, was elected president of the Denver Public Health Council, January 12; Dr. Estella F. Warner, Washington, D. C., addressed the meeting on "Child Welfare in Colorado."——Dr. Gerald B. Webb, Colorado Springs, addressed the El Paso County Medical Society, February 10, on "The Prescription of Literature."——The Mesa County Medical Society was addressed, February 16, by Dr. Frank J. McDonough on "Modern Treatment of Burns with Special Reference to Tannic Acid"; Dr. Elliott S. Stong, Grand Junction, "Management of War Hospitals and War Surgery," and Mr. Robert Whipple, "Filtrability of Bacteria."——Among others, Dr. Gerrit Heusinkveld, Denver, addressed the Otero County Medical Society, February 11, in La Junta, on "Management of Difficult Labor."

CONNECTICUT

Dr. Maher Awarded Medal.—Dr. Stephen J. Maher, New Haven, was awarded the Laetare Medal by the University of Notre Dame, South Bend, Ind., March 6. Dr. Maher, who is 71 years old, is the forty-ninth recipient of the award, the New York *Times* states. He graduated from Yale University School of Medicine, and, since 1900, has been actively engaged in the study of tuberculosis. He has been chairman of the Connecticut tuberculosis commission since 1913 and was at one time president of the New England Conference on Tuberculosis.

Change in Wassermann Technic.—The bureau of laboratories, Connecticut State Department of Health, discontinued the use of the plain alcoholic antigen as a routine part of the Wassermann test, February 1, because the plain alcoholic antigen was found less sensitive than the cholesterinized alcoholic antigen in the regular routine, and because research undertaken by the laboratories in 1931 to determine the most practical serologic procedure for its purposes definitely confirmed the routine observations. This problem comprised the serologic examinations of 3,000 specimens by each of five different tests. Furthermore, it was felt that the change would give the laboratory the opportunity to satisfy the demand for an extension of the use of the Kahn precipitation test in conjunction with the Wassermann test.

DELAWARE

Health at Wilmington.—Telegraphic reports to the U. S. Department of Commerce from eighty-three cities with a total population of 36 million, for the week ended March 5, indicate that the highest mortality rate (25.5) appears for Wilmington, and the rate for the group of cities as a whole, 13.4. The mortality rate for Wilmington for the corresponding period last year was 18.6, and for the group of cities, 13.8. The annual rate for eighty-three cities for the nine weeks of 1932 was 12.3, as against a rate of 14.3 for the corresponding period of last year. Caution should be used in the interpretation of weekly figures, as they fluctuate widely. The fact that some cities are hospital centers for large areas outside the city limits, or that they have large Negro populations, may tend to increase the death rate.

FLORIDA

Society News.—Dr. Charles W. Stiles, Washington, D. C., addressed the Orange County Medical Society, January 20, on eradication of hookworm disease.——A symposium on the value of the Mantoux tuberculin reaction in the diagnosis of the childhood type of tuberculosis was presented before a recent meeting of the Columbia County Medical Society by Drs. Louie M. Limbaugh, Thomas M. Palmer and Wilfred M. Shaw, Jacksonville.

GEORGIA

Another "Doctor" Sentenced.—"Dr." Randall Boyd Ramsey is now serving a two year sentence in the U. S. penitentiary Annex, Fort Leavenworth, Kan., for violation of the Harrison Narcotic Act. At Macon, Ramsey procured morphine on forged internal revenue forms stolen from Dr. Henry A. Vann, Boston, Ga. Prior to this time, it is reported, he had been convicted of a violation of the Harrison Narcotic Act at Jacksonville, Fla., and fined $500. On another occasion, he was convicted and fined $50 for a similar violation. Ramsey himself is said to be an addict. He claims to be a practicing physician, stating, it is said, that he received his degree of doctor of medicine from the University of Louisville, Ky., about 1890, and that he practiced in Tennessee and Georgia. Correspondence indicates, however, that the dean of the University of Louisville School of Medicine was unable to find any record that Ramsey ever attended that school. The secretaries of the Tennessee, Georgia, Kentucky and Florida state medical boards have also reported that Ramsey's name does not appear in their records. There is no record in the files of the American Medical Association that this man was ever graduated from a medical school or licensed to practice medicine.

Fischer Prizes Awarded.—Dr. Frank Lee Bivings, Atlanta, was awarded the 1931 L. C. Fischer Prize for research for a paper on "Eczema in Infancy and Childhood—Its Relation to Allergy," and Dr. Mark Stovall Dougherty, Jr., Atlanta, the prize for the best written paper, "Toxic Reactions Produced by the Derivatives of Barbituric Acid." In 1925 Dr. Luther C. Fischer, to stimulate interest in research and to improve medical writing, established the L. C. Fischer prizes to be awarded through the Fulton County Medical Society. Two prizes of $100 each have been available every year. Winners of the awards in previous years are: 1925, both prizes by Dr. Madison Hines Roberts, Atlanta, "Spinal Fluid in the New-Born with Special Reference to Intracranial Hemorrhage"; 1926, both prizes, Dr. Daniel C. Elkin, "Postoperative Atelectasis of the Lung"; 1927, prize for research by Dr. Roberts, "Relations of Pigment Content in the Serum and Spinal Fluid of New-Born Infants"; 1928, no paper considered worthy of either award; 1929, Dr. Launcelot Minor Blackford, for best written paper on "Tetralogy of Fallot"; 1930, Dr. Jack C. Norris, Decatur, prize for research, "A Yeast Pathogenic for Man and Animals (Saccharomyces Pleomorphus-Virulens)," and Dr. John B. Cross, "Fatal Hepatogenic Hypoglycemia Following Neoarsphenamine."

ILLINOIS

Society News.—Dr. Leon Unger, Chicago, addressed the Iroquois County Medical Society at Watseka, February 25, on "Recent Advances in the Treatment of Asthma and Hay Fever."——Dr. Andrew J. Boston, Albion, was elected president of the newly reorganized Edwards County Medical Association, and Dr. Herman L. Schaefer, West Salem, secretary.——Dr. Ellis Fischel, St. Louis, addressed the St. Clair County Medical Society at Belleville, March 2, on "Use of Radium in Malignancy." Dr. Frank J. Tainter, St. Louis, addressed the society, March 3, in East St. Louis on "Problems of Thyroid Surgery."——Dr. William W. Graves, St. Louis, addressed the Madison County Medical Society, March 4, at Alton on "Practical Basis in the Diagnosis of Neurologic Conditions."

Increase in Rabies.—A sharp increase in the prevalence of rabies among dogs has been observed by the state department of public health during the last two months. Positive tests for rabies were made of thirty-nine animal heads, mostly dogs, in the laboratories of the department during January and February of this year, compared with nineteen for the corresponding month of 1931, an increase of more than 100 per cent. There were 197 positive tests made in the laboratories during 1931. Distribution centered in Cook County, Sangamon County and in Jefferson County in a way that almost duplicated the 1926 experience, which marked the beginning of an epidemic wave that reached a peak in 1928, when 1,471 positive tests were made and fourteen human deaths from rabies were recorded.

Chicago

Personal.—The Medical Women's Club of Chicago gave a dinner, February 10, in honor of Dr. Bertha Van Hoosen, head of the department of obstetrics in Loyola University Medical School.

Naprapath Sentenced.—Olive Kendall Harvey, naprapath, was sentenced to one year in the county jail and fined $200 and costs, February 24, for violation of the medical practice act. Among various complaints to the state department of registration are charges that the woman has performed abortions. She has never had a license of any kind in this state, the department reports. In 1927 she was fined $100 on a charge of practicing medicine without a license (The Journal, July 16, 1927, p. 212).

Society News.—At the meeting of the Chicago Gynecological Society, March 18, the speakers were Drs. Pashupati J. Sarma and George De Tarnowsky on ovarian embryoma and Gustav Kolischer, urologic conditions in women.——At a recent meeting Dr. Robert B. Preble was elected president of the Chicago Heart Association and Dr. Sidney Strauss, secretary.——The Chicago Neurological Society was addressed, March 17, among others, by Dr. William F. Lorenz, Madison, Wis., on "Confessions Obtained During Narcosis."——Dr. Leo L. Mayer, among others, addressed the Chicago Ophthalmological Society, March 21, on "Visual Fields, Blind Spots and the Optic Disks in Endocrine Diseases."——The Chicago Society of Allergy will be addressed, March 21, by Drs. Paul R. Cannon and William L. Beecher on "Studies in Tissue Immunity" and "Allergy as a Factor in Ulcers of the Digestive Tract," respectively.

INDIANA

Society News.—Dr. Homer G. Hamer, Indianapolis, addressed the Grant County Medical Society at Marion, February 23, on "Palliative Treatment of Prostatism."——The Fountain-Warren County Medical Society was addressed at Covington, March 3, by Dr. Edward B. Ruschli, La Fayette, on "Diagnosis and Care of Toxic Goiter."——At the March 2 meeting of the Marshall County Medical Society, Dr. Paul R. Irey, Plymouth, spoke on "Treatment of Gonorrhea in Male and Female."

IOWA

Personal.—Dr. Finis C. Suggett, Columbia, Mo., became director of the Des Moines County Health Unit, effective February 1. He succeeded Dr. Carl F. Jordan, who will return to the University of Iowa as assistant professor of hygiene and preventive medicine, it is reported.

Society News.—The Carroll County Medical Society was addressed, January 7, by Drs. Aldis A. Johnson, Council Bluffs, and John C. Parsons, Creston, on "Diagnosis and Treatment of Parasitic Diseases of the Intestinal Tract" and "Mistakes in Diagnosis," respectively.——The Des Moines Academy of Medicine and the Polk County Medical Society were addressed, February 23, by Drs. Francis A. Ely and Elmer E. Kottke on "Acute Infective Polyneuritis" and "Heart Sounds and Their Clinical Significance," respectively.——Dr. Philip B. McLaughlin, Sioux City, was elected president of the Sioux Valley Medical Association at its annual meeting recently, and Dr. William Roscoe Jepson, Sioux City, secretary.

LOUISIANA

Society News.—A symposium on diphtheria immunization comprised the program of the Orleans Parish Medical Society at its meeting, February 22. The speakers were Drs. William H. Robin, Robert A. Strong and John A. Signorelli, New Orleans. Drs. Noka B. Hon, New Orleans, and Ralph L. Lawrence, Washington, D. C., among others, addressed the society at its clinical meeting at the U. S. Marine Hospital, New Orleans, March 14, on "Diathermy in Treatment of Paresis" and "Results in the Treatment of Pernicious Anemia," respectively.——Dr. John H. Musser, New Orleans, addressed the East West Feliciana Bi-Parish Medical Society in Jackson, February 3, on "Some Facts About Nutrition."

MAINE

Society News.—Dr. Joseph W. Scannell, Lewiston, addressed the Androscoggin County Medical Society at Lewiston, February 5, on "The Acute Abdomen."——The Cumberland County Medical Society heard a talk on "Pasteurization of Milk," given by Dr. Milton J. Rosenau, Boston, January 29. ——At the meeting of the Penobscot County Medical Society, February 16, Dr. Ernest M. Daland, Boston, spoke on "Accepted Methods in the Treatment of Cancer."

MARYLAND

Diphtheria Immunization Campaign.—With the endorsement by the Baltimore City Medical Society and the Colored City Medical Society, the city health department has begun a campaign for diphtheria immunization in Baltimore. An effort is being made during March and April to have as many parents as possible take their children to their private physicians for the treatments. Later, clinics will be held to care for those who are unable to afford a physician for the service. Certificates of immunization and circulars for the use of physicians in their practice are now being printed for distribution, April 1.

Increase in Venereal Disease Clinic Attendance.—During 1931 there were 57,043 visits made to the three Baltimore venereal disease dispensaries for examination, treatment and advice. This was an increase of 16,521 over the preceding year. Treatment for syphilis given to white patients numbered 6,832 and to Negroes, 29,487. Gonorrhea treatments totaled 4,539 for white patients and 12,060 for Negroes. There were 128 chancroid treatments given to white patients and 2,870 to Negroes; 2,339 more Wassermann tests were made than during the preceding year. According to the director of the bureau of communicable diseases of Baltimore, this increase is partly explained by present economic conditions. The city clinics are the only clinics where treatment is free and which are open at night.

Dr. Dochez to Give Thayer Lectures.—Dr. Alphonse R. Dochez, professor of medicine, Columbia University College of Physicians and Surgeons, New York, will give the fifth course of lectures under the William Sydney Thayer and Susan Read Thayer Lectureship in clinical medicine at Johns Hopkins Hospital, March 22-23. Dr. Dochez will speak on "A Limited Consideration of Certain Aspects of Acute Infection of the Respiratory Tract." May 16, 1927, a group of friends and admirers of Dr. William Sydney Thayer donated a fund to Johns Hopkins University to endow a lectureship to be known as "The William Sydney Thayer and Susan Read Thayer Lectureship in Clinical Medicine." According to the terms of the gift, the income of this fund is to be used to defray the expenses of one or more annual lectures on subjects in clinical medicine, pediatrics, neurology or borderline branches.

Quarter Century Editions of Medical Annals.—Dr. John Ruhräh, Baltimore, has been appointed by the Medical and Chirurgical Faculty of Maryland to prepare the history of the medical profession in the state for the last twenty-five years. In 1927, Dr. Thomas S. Cullen, in his presidential address, spoke on "Early Medicine in Maryland." Recalling Dr. Eugene Fauntleroy Cordell's book on the "Medical Annals of Maryland," he suggested that the state's medical history be brought up to date. It was decided then, the faculty's bulletin states, that this should be done, if possible, in quarter century editions. The work is now well under way, and divisions have been made covering the growth and development of Maryland's hospitals and medical schools as well as the administration of city and state departments of health. Dr. Ruhräh, as editor of this new history, is being assisted by many collaborators covering the various branches of medicine.

MASSACHUSETTS

License Restored.—The license to practice medicine in Massachusetts of Dr. Irving F. Armstrong, Hudson, was restored to him, March 3. Dr. Armstrong's license had been revoked for conviction on a charge of conspiracy in connection with claims for personal injury in automobile accident insurance cases, the state board of registration reports.

New Administrative Plan.—With the adoption of a new plan of administrative organization the Massachusetts Institute of Technology, March 9, is subdivided into five departments —the School of Science, School of Engineering, School of Architecture, Division of Humanities and the Division of Industrial Cooperation. The School of Science includes biology and public health, chemistry, geology, general science, mathematics and physics. The three schools are the departments in which degrees are given, whereas the two divisions are essentially service divisions, the New York *Times* states. The study of hygiene will be included in the Division of Humanities. The new organization provides for an administrative council, an informal body which will meet weekly for reports of progress in the various departments.

MICHIGAN

Society News.—Dr. George B. Eusterman, Rochester, Minn., addressed the Wayne County Medical Society, Detroit, March 15, on "Incidence and Nature of Gastric Lesions Masquerading as Benign Disease."——Dr. Adolph E. Voegelin, Detroit, recently delivered four lectures on cardiology at the Evangelical Deaconess Hospital.

Examination of Children for Tuberculosis.—An antituberculosis campaign is being carried on in Wayne County during March and April, by representatives of the Wayne County Medical Society, health departments of the county, the Detroit Roentgen Ray Society and the Detroit Tuberculosis Society. Letters are being sent to parents of children in grade and high schools asking them to have each child examined for tuberculosis by the family physician, who will record his observations on a record card enclosed with the letter. Those who do not have a private physician are to be referred to a cooperating physician in their districts. Positive reactors will be carefully examined and a brief history will be taken with particular reference to contacts, all information to be recorded on special forms. They will then be referred for roentgen examination. Roentgenologists have agreed to accept each physician's statement as to the ability of the parent to pay for the service. Parents unable to pay even a part of the cost may be sent to the Herman Kiefer Hospital, where the roentgen examination will be made without charge and a report sent to the referring physician. No charge will be made by physicians if the parents are unable to pay. A charge of one dollar will be made if the child comes to the physician's office for the tuberculin test and the physical examination during the hours specified for the purpose. This arrangement interferes in no way with charging a regular fee for this examination when it is conducted at other hours or on adults and contacts. Tuberculin, forms for recording histories and physical observations, lists of cooperating roentgenologists and technical instruction are to be supplied by the Detroit Department of Health. Contacts are to be followed up and referred to either the family or the cooperating physician.

MINNESOTA

University News.—Dr. Hilding Berglund has resigned as professor of medicine at the University of Minnesota Medical School, Minneapolis, effective June 30, 1933. He will spend the year beginning July 1, 1932, in absentia. Jesse F. McClendon, Ph.D., professor of physiologic chemistry at the university, was to have left about the middle of March to spend a year as visiting professor under the Rockefeller Foundation at the Tohoku Imperial University, Sendai, Japan.

Society News.—At the meeting of the Minnesota Radiological Society in Minneapolis, February 13, the addresses included "Recent Literature on the Classification and Treatment of Bone Tumors" by Dr. William A. O'Brien, and "Cholecystographic Studies on the Emptying of the Human Gallbladder," by Edward A. Boyden, Ph.D.—The Minnesota Academy of Medicine was addressed, March 9, by Drs. Clayton K. Williams, St. Paul, on "Nonspecific Protein Therapy"; William F. Braasch, Rochester, "Recurring Renal Lithiasis of Unusual Type," and Emil S. Geist, Minneapolis, "Knee Fusion."

MISSOURI

Hospital News.—An endowment of $250,000 has been given to St. Luke's Hospital, Kansas City, by Mrs. Herbert F. Hall. The income will be used to pay part or all of the hospital expenses in selected cases, to relieve in part or entirely the burden of the expense of illness which requires hospital care for families with a budget of from $2,000 to $3,000. An operating room at the hospital was recently dedicated to the memory of Dr. Herbert G. Trueman who died in 1928. The room was given to the hospital by Mrs. Trueman.

Medical School Committee Appointed.—Dr. Albert J. Welch, Kansas City, president of the Jackson County Medical Society, recently appointed a committee to act in the interest of procuring for Kansas City the last two years of medical instruction for students at the University of Missouri. The committee includes Drs. Edwin Lee Miller, Buford G. Hamilton, Minford A. Hanna, Jabez N. Jackson and Edward P. Heller. In 1930 the reestablishment of the clinical years at the University of Missouri, Columbia, was authorized. They had been discontinued in 1909 (The Journal, Oct. 18, 1930, p. 1185).

Society News.—Dr. Hugh Cabot, Rochester, Minn., among others assisting in the hospital clinic of the Kansas City Southwest Clinical Society, March 8, spoke on "The Management of Cancer of the Prostate." He also addressed the Jackson County Medical Society in the evening on "Place of Nephrostomy in the Treatment of Kidney Lesions." Drs. Nelse F. Ockerblad and Ernest G. Mark spoke on "Correction of Vesical Neck Obstructions by Means of the Resectoscope" and "An Attempt to Evaluate Transurethral Prostatectomy in Bladder Neck Obstructions," respectively.——At the meeting of the St. Louis Medical Society, February 23, Dr. Horace W. Soper spoke on "Diagnosis of Carcinoma of Colon," and Dr. John W. Thompson, Jr., talked on "Surgical Treatment of Carcinoma of Colon with Report of Forty-Five Cases." The society was addressed, February 16, by Drs. Lawrence Schlenker on "Pneumothorax as a Home Treatment"; Wilbur K. Mueller, "Spontaneous Pneumothorax," and Edgar W. Spinzig, "Massive Collapse (Atelectasis) of the Lung." Clinical cases were presented at the meeting of the St. Louis society, March 1. A brief summary of the life of the late Dr. Theodore F. Prewitt was also read at this meeting, as a centennial tribute. Dr. John C. Meakins, Montreal, Canada, addressed the society, March 8, on "Bronchial Carcinoma."——At the meeting of the Jackson County Medical Society, March 15, the speakers were Drs. David S. Dann, Kansas City, on "X-Ray Examination of the Spine"; Frank D. Dickson, Kansas City, "Shelf Operation for the Correction of Congenital Hip Disease," and Samuel A. Grantham, Joplin, "Spinal Fusion by the Tunneling Method."

NEW YORK

Report on Workmen's Compensation Laws.—A committee appointed by Governor Roosevelt to review problems connected with workmen's compensation insurance, has presented a report of its studies during the year. The subcommittee on hospital problems, of which Dr. Sigismund S. Goldwater is chairman, made the following recommendations: that hospitals be adequately paid for service in compensation cases without regard to the "ward charity" rate; that authorization by the employer for payment of hospital charges should not be required; that a law be enacted giving a hospital liens on judgments awarded to patients in damage suits, and that hospitals be advised within a definite time whether cases are to be contested. The subcommittee on medical problems, of which Dr. Adrian V. S. Lambert is chairman, recommended that all occupational diseases be included in the provisions of the workmen's compensation act; that insurance company physicians be excluded from physical examinations of claimants; that the practice of "lifting" (defined as the practice on the part of insurance agents of inducing compensation claimants to change medical attendants by means of threats or offers of a pecuniary nature) be prohibited, under penalty of forfeiture to the state of a sum ranging from $50 to $150. The committee on medical problems further expressed the opinion that the maintenance of clinics by insurance companies is unsatisfactory and suggested that a series of clinics be created under supervision and direction of the state. Two members representing insurance companies dissented from the foregoing opinion. The committee also recommended that total disability be interpreted to mean that the injured person is unable to return to his occupation and should be compensated until he can resume it, with the exception that any earnings from light work in the meantime be deducted from compensation. Although present conditions are unsatisfactory, they do not warrant free choice of physicians by patients, the committee believed. Finally, the committee suggested the formation of a "supreme court of review" made up of seventy-five unbiased experts from which committees could be drawn to solve certain highly specialized medical problems. A third committee on departmental procedure, headed by Mr. Max Meyer, recommended, among other things, creation of a bureau to which a claimant might go for impartial checkup on his treatment; provision of suitable examination rooms in every city and recognition of the principle that a man injured while working should not become a burden to society because his employer is not insured. Suggested bills to be submitted to the legislature were presented to the governor covering (1) elimination of authorization by employers, (2) the right of hospitals to adequate remuneration and (3) elimination of right of carriers or employees to be represented at physical examinations of injured persons. Howard S. Cullman, New York, is chairman of the governor's committee.

New York City

Study of Incipient Tuberculosis in Children.—The Queensboro Tuberculosis and Health Association is directing a three-year study of tuberculosis in 22,000 school children of the borough of Queens, it was recently announced. Roentgenograms are being made of all the children's chests and it is planned to repeat the examination next year and the next, thus making available three consecutive films for each child. The board of education, the city health department, Bellevue Hospital, Nassau County Hospital and the medical department of the New York Telephone Company are cooperating in the study, according to the report.

Hospital News.—A new $125,000 hospital building at Mitchell Field, L. I., was occupied, February 20, replacing an old structure. It has a capacity of twenty-five beds and a specially equipped optical room for eye examinations of pilots. ——The Veterans Administration Hospital in the Bronx is in process of conversion from a hospital for nervous and mental patients to a general hospital. Neuropsychiatric patients have been transferred to hospitals at Northport, L. I., and Reliance, N. J. Because of an increase in the number of patients requiring general treatment, it was found necessary to make provision for them in New York City. Such cases have heretofore been cared for at the naval hospital in Brooklyn.

Milbank Fund Council Meeting.—At a meeting of the advisory council of the Milbank Memorial Fund, March 16-17, Dr. William H. Welch, Baltimore, resigned as chairman of the council, a position he had held since its organization in 1922. Dr. Livingston Farrand, Ithaca, was chosen to succeed him. The council met in groups, in which discussions were held on health centers, health education and tuberculosis in children, population studies and public health nursing. Among speakers were Drs. William H. Park, Shirley W. Wynne and James Alexander Miller, New York; Thomas Parran, Jr., Albany, and Raymond Pearl, Ph.D., Baltimore. Dr. Hsun-Yuan Yao described the fund's health demonstration in Ting Hsien, China (The Journal, Sept. 5, 1931, p. 714). Discussions on economics of medicine and health were presented by the following speakers, among others: Dr. Ray Lyman Wilbur, Washington, D. C.; Louis I. Dublin, Ph.D., New York, and Charles-Edward A. Winslow, Dr.P.H., New Haven, Conn.

OHIO

Graduate Course in Physiology.—Dr. Anton J. Carlson, professor of physiology, University of Chicago, will conduct the tenth annual graduate course sponsored by the Toledo Academy of Medicine, March 21-25, on recent advances in physiology. Dr. Carlson will give two lectures each day, covering, among other subjects, the anemias, control of the heart, control of blood pressure, oxygen therapy, the digestive secretions, motor mechanisms of the alimentary tract, dietary deficiencies, the endocrine glands and renal function.

Society News.—Drs. Cyrus C. Sturgis, Ann Arbor, Mich., and Marion A. Blankenhorn, Cleveland, addressed the Cleveland Academy of Medicine, March 18, on "The Outlook of the Patient with Pernicious Anemia" and "Neurological Aspects of Pernicious Anemia," respectively.——The Cleveland Neurological Society was organized, February 4, with Dr. Siegfried Baumoel as chairman and Dr. William James Gardner as secretary.——Dr. Henry D. Chadwick, Detroit, addressed a joint meeting of the medical section of the Toledo Academy of Medicine and the Toledo Public Health Association, March 18, on "The Childhood Type of Tuberculosis." This meeting celebrated the fiftieth anniversary of Koch's discovery of the tubercle bacillus, March 24, 1882.

PENNSYLVANIA

Governor Vetoes Hospital Bill.—Governor Pinchot recently vetoed a $2,000,000 hospital aid bill passed by the special session of the legislature. The governor said he could not approve the measure because it did not provide revenue for the appropriation and because in his opinion the basis of distribution had no relation to the requirements of the individual hospitals. The bill apportioned the fund among the state's hospitals on the basis of 27 per cent of the 1931 appropriation.

Society News.—Dr. William W. G. MacLachlan, Pittsburgh, addressed the Mercer County Medical Society, February 17, on pneumonia.——Dr. Adam C. Williamson, Pittsburgh, addressed the Fayette County Medical Society, Uniontown, March 3, on "Management of Occiput Positions."——Speakers at the meeting of the Pittsburgh Academy of Medicine, March 8, were Drs. Charles H. Henninger, on "Borderline Mental States"; David Silver, "Bone Setting and Allied Cults," and Andrew Wallhauser, "Treatment of Hodgkin's Disease."——At a meeting of the Cambria County Medical Society, Johnstown, March 10, Dr. Frederick M. Allen, Morristown, N. J., spoke on "Diet and Other Measures in Treatment of Nephritis" and Drs. Bernard J. McCloskey, Joseph P. Replogle and John W. Barr presented a review of research and study in medicine, surgery and [illegible] tively.——John J. Moffitt, D.D.S., addres[illegible] Academy of Medicine, February 16, on [illegible] Abscessed Tooth."

Philadelphia

Hospital News.—The Jeanes Hospital instituted a radium service recently with the completion of an emanation plant and the purchase of 1 Gm. of radium. Another gram of radium is on order and will be delivered shortly, according to the medical director.——The merger of the West Philadelphia Hospital for Women with the Woman's Hospital of Philadelphia, announced in 1928, was consummated, February 16, when the personnel of the former institution was moved to the new $530,000 building of the latter in West Philadelphia.

Founder's Day Celebration.—The one hundred and eleventh anniversary of the founding of the Philadelphia College of Pharmacy and Science was celebrated, February 23. C. Leonard O'Connell, Pharm.D., of the University of Pittsburgh College of Pharmacy, made an address on education of the pharmacist. H. K. Mulford presented to the college the fifth of a series of mural paintings depicting the progress of pharmacy. The honorary degree of master of pharmacy, honoris causa, was conferred on Dr. O'Connell.

Hospital Deficits.—Private hospitals in Philadelphia incurred a deficit in 1931 of $726,440, it was revealed at a meeting of the subscribers to the Welfare Federation, February 29. Dr. J. Norman Henry, director of public health, stated that public hospitals are overcrowded; the Philadelphia Hospital for Mental Diseases, for example, has 5,100 patients, when it is equipped to care for only about 3,000. In pleas for further aid for private hospitals, it was pointed out that large numbers of persons who were formerly pay or part-pay patients are now forced to become charity patients.

Society News.—Dr. Rosco G. Leland, Chicago, will address the Philadelphia County Medical Society, March 23, on "Trends in Medical Economics" and Dr. George P. Muller, on "The Public and the Medical Profession."——The meeting of the Philadelphia Neurological Society, March 18, was dedicated to the memory of Dr. Charles K. Mills, one of the founders. The following speakers discussed various phases of the career of Dr. Mills and his relation to the society: Drs. William G. Spiller, Charles W. Burr, James W. McConnell, Williams B. Cadwalader, Charles H. Frazier, Theodore H. Weisenburg and James Hendrie Lloyd.——Dr. John Alexander, Ann Arbor, Mich., gave a lecture, March 18, under the auspices of the D. Hayes Agnew Surgical Society, on "The Widening Scope of Thoracic Surgery."

TENNESSEE

Society News.—Dr. John Howard King addressed the Nashville Academy of Medicine, February 23, on acne. Dr. Thomas A. Mitchell spoke, March 1, on "Symptoms Due to Impairment of Kidney Function and Acidosis," and Dr. Fred W. Rankin, Rochester, Minn., March 8, on "Encouragement in Dealing with Colonic Malignancies."——Dr. Harold M. Bowcock, Atlanta, Ga., addressed the Hamilton County Medical Society, Chattanooga, February 11, on "Newer Considerations in the Treatment of Diabetes Mellitus." Drs. Stewart Lawwill and James D. L. McPheeters, Chattanooga, spoke, February 18, on sinus diseases.——Drs. Samuel T. Ross and Edwin A. Sayers, Nashville, among others, addressed the Hardin-Lawrence-Lewis-Perry-Wayne Counties Medical Society, January 26, on "Surgical Treatment of Cirrhosis of the Liver with Ascites" and "Diagnosis and Treatment of Fractures of the Skull," respectively.——Dr. James A. Price, Memphis, was elected president of the Tennessee Tuberculosis Association at the recent annual meeting in Nashville.——Drs. Richard A. Barr and Jefferson C. Pennington, Nashville, addressed the Giles County Medical Society, Pulaski, January 28, on appendicitis and surgery of the neck of the bladder, respectively.——Drs. Morton J. Tendler and Thomas D. Moore, Memphis, addressed the Memphis and Shelby County Medical Society, January 19, on "Pilonidal Sinus" and "Instrumental Correction of Prostatic Obstruction," respectively.——Dr. H. C. Long addressed the Knox County Medical Society, Knoxville, March 1, on cardiac arrhythmia. Dr. Philip C. Thomas, Knoxville, addressed the society, March 8, on "Placenta Praevia."

Dr. [illegible] Library
[illegible] Medical College

TEXAS

Spring Clinical Conference.—The fourth annual spring clinical conference sponsored by the Dallas Southern Clinical Society will be held, March 28-April 2, in Dallas, with headquarters at the Baker Hotel. There will be addresses by guest speakers each morning and evening and round table luncheons each day at noon, while the afternoons will be devoted to clinics at various hospitals and to a series of graduate lectures. At the opening meeting, March 28, Dr. Edward H. Cary, Dallas, President-Elect, American Medical Association, will make an address of welcome and the following physicians will speak: Drs. Thomas R. Brown, Baltimore, on "The Story of Digestion —and Indigestion"; Frank H. Lahey, Boston, "The Thyroid Gland," and Karl A. Menninger, Topeka, Kan., "Suicide: Its Meaning and Its Prevention." Among other guest speakers listed for the week are Drs. Herman L. Kretschmer, Chicago, "Treatment of Pyelitis"; Samuel A. Levine, Boston, "Bedside Recognition of Irregularities of the Heart"; Merrill C. Sosman, Boston, "Roentgenological Observations on the Cure of Gastric and Duodenal Ulcers"; Williams McKim Marriott, St. Louis, "Practical Points in the Care and Feeding of Infants"; Lee Wallace Dean, St. Louis, "Relationship Between Infections of the Upper Respiratory Tract and Pediatric Conditions"; Udo J. Wile, Ann Arbor, Mich., "Skin Manifestations of Systemic Disease"; John Shelton Horsley, Richmond, Va., "Diagnosis and Treatment of Cancer of the Colon"; William O'Neill Sherman, Pittsburgh, "Surgery of Trauma"; Carl A. Hedblom, Chicago, "Treatment of Empyema"; Paul Titus, Pittsburgh, "Toxemias of Pregnancy"; Edward H. Richardson, Baltimore, "Interpretation of Abnormal Uterine Bleeding"; John A. Kolmer, Philadelphia, "Present Status of Vaccine and Nonspecific Protein Therapy"; Joseph C. Beck, Chicago, "Neoplasms About the Head and Neck"; Dudley A. Smith, San Francisco, "Cancer of the Rectum," and Albert H. Rowe, Oakland, Calif., "Food Allergy." In addition, there will be symposiums on disease of the biliary tract, conservation of maternal health and arthritis. The annual clinic dinner and alumni reunion will be held, Wednesday evening, March 30. Both scientific and technical exhibits will be on view.

WISCONSIN

Society News.—Drs. Harry J. Fortin and Albert M. Snell, Rochester, Minn., addressed the Rock County Medical Society, Beloit, February 23, on "Arthritis and Its Treatment" and "Diagnosis and Treatment of Peptic Ulcer," respectively.——Drs. Forrester Raine, Milwaukee, and Leon Bloch, Chicago, addressed the Racine County Medical Society, February 17, on "Intestinal Obstruction" and "Genito-Urinary Conditions Simulating Gastro-Intestinal Diseases," respectively.——At a joint meeting of the Menominee and Marinette-Florence county medical societies, Menominee, February 18, Drs. Lloyd E. Hamlin, Norway, and Moses Cooperstock, Marquette, spoke on "Treatment of Burns" and "Advances in Treatment of Childhood Conditions," respectively.

Chapel and Library Given to Hospital.—Dedication ceremonies were held, February 21, for a chapel and a library which have been given to St. Luke's Hospital, Racine, by Dr. John G. Meachem, Jr. The chapel is a memorial to Dr. Meachem's wife, and the library to three generations of his family who have been physicians. The chapel seats fifty persons. The library contains more than 1,500 volumes. It also provides a meeting place for physicians and will probably be used by the Racine County Medical Society for its monthly meetings. Dr. Meachem, who is 86 years old, has practiced medicine for sixty-seven years. He was for many years a member of the municipal health board of Racine. With his father, Dr. John G. Meachem, Sr., he was one of the incorporators of St. Luke's hospital. His son, Dr. John G. Meachem III, who died in 1926, left the hospital an endowment of $180,000.

GENERAL

Education of the Handicapped.—Miss Beatrice McLeod, former state director of special education in Wyoming, has been appointed specialist in the education of physically handicapped children in the Office of Education, U. S. Department of the Interior. She will report work being done on behalf of all children with physical handicaps, cooperate with agencies and school officials, assist in surveys, and conduct studies to aid in the promotion of special treatment and training. Miss McLeod is a graduate of the University of Oregon and has been connected with the department of child study in Seattle and the department of psychology and educational research in Los Angeles. Her appointment marks an expansion of the activities of the office of education.

Dental Association Adopts Publicity Program.—The board of trustees of the American Dental Association, at a meeting in Chicago, January 18, approved plans for an organized program of educational publicity, submitted by a committee appointed previously. Three methods were contemplated in the report. "Educational messages," prepared either by the committee or by local dental societies with the committee's approval, will be presented through newspapers and other mediums to the public. A publicity director is to be appointed to prepare copy under supervision of the committee. The third feature of the plan is the use of the radio for dissemination of oral, dental and general health topics, the subject matter to be approved by a special committee.

National Negro Health Week.—The eighteenth annual observance of National Negro Health Week will be held, April 3-10. This movement was started in 1915 by Booker T. Washington as a National Health Improvement Week. When the U. S. Public Health Service assumed an active interest in the promotion of National Negro Health Week in 1921, plans were made for developing it into a year-round program for the improvement of the health of the colored population. The program for 1932 emphasizes practical health measures such as clinics, clean-up activities, and efforts to secure permanent health improvements and full time colored health workers. It is being arranged by the annual Tuskegee conference and other Negro organizations in cooperation with the U. S. Public Health Service.

Another Four Weeks of Automobile Fatalities.—The U. S. Department of Commerce announces that during the four weeks ended February 20, eighty-three large cities in the United States reported 604 deaths from automobile accidents as compared with 618 deaths during the four weeks ended Feb. 21, 1931. Most of these deaths were the result of accidents which occurred within the corporate limits of the city, although some accidents occurred outside the city limits. Considered by four week periods since January, 1929, total deaths from automobile accidents, whether within the city limits or outside, the lowest total (472) appears for the four-week period ended Feb. 23, 1929, and the highest (867) for the four week period ended Jan. 23, 1932. For the fifty-two week periods ended Feb. 20, 1932, and Feb. 21, 1931, the totals for all the cities were, respectively, 9,127 and 8,968, which indicate a recent rate of 25.5 per hundred thousand of population, as against an earlier rate of 25.6.

Medical Bills in Congress.—*Changes in Status:* S. 1975 has passed the Senate, amending an act entitled "An Act to recognize the high public service rendered by Major Walter Reed and those associated with him in the discovery of the cause and means of transmission of yellow fever" by including Dr. Roger P. Ames among those honored by the act. S. J. Res. 65 has been indefinitely postponed by the Senate, proposing to extend the provisions of the World War Veterans' Act relating to hospitalization for nonservice disabilities to include any veteran who was honorably discharged from any term of service during the war, whether or not a subsequent period of service was terminated dishonorably. *Bills Introduced:* H. R. 10202, by Representative Shannon, Missouri, to authorize the purchase of the hospital leased by the Veterans' Administration at Kansas City, Mo. H. R. 10238, by Representative Leavitt, Montana, to create a reimbursable fund to be used for special medical and surgical work among the Indians of the Fort Peck Indian Reservation, Montana.

Society News.—The fifty-ninth annual meeting of the Northern Tri-State Medical Association (Ohio, Indiana and Michigan) will be held in Toledo, Ohio, April 12. Clinics will be conducted by Drs. Ora O. Fordyce and Newton W. Kaiser, Toledo, in psychiatry; Edward P. Gillette, Toledo, orthopedic surgery, and Udo J. Wile, Ann Arbor, Mich., dermatology. Among others, Drs. Stanley P. Reimann, Philadelphia, will speak on "Sulphydril—The Basis for Further Cell Division," and Dr. Dean Lewis, Baltimore, will speak at the annual banquet on "Lesions of Bone and Their Treatment."——Dr. Emmet Rixford, San Francisco, was elected president of the Pacific Coast Surgical Association at its annual meeting in Santa Barbara, February 25-27; Drs. Wayland A. Morrison, Los Angeles, and William B. Holden, Portland, Ore., were elected vice presidents, and Dr. Edgar L. Gilcreest, San Francisco, was reelected secretary. The eighth annual meeting of the association will be held at Del Monte, Calif., Feb. 24-26, 1933. Preceding this meeting, there will be two days of clinics in San Francisco.

Decrease in Consumption of Medicinal Whisky.—During the past year there has been a reduction of 14 per cent in the distribution and use of medicinal whisky, according to a recent statement of James M. Doran, commissioner of industrial alcohol, before a subcommittee of the committee on appropriations of the House of Representatives at Washington. In 1931, the amount of medicinal liquor consumed was 1,201,000 gallons, as compared with 1,405,000 gallons in 1930. During the month of January, 1932, the consumption amounted to 107,768 gallons, in comparison with 143,642 gallons in January, 1931. The commissioner attributed the reduction to the higher price of medicinal spirits. "Medicinal whisky has gone up in price by reason of the increased carrying cost that follows from year to year and as it steadily evaporates each year and the interest and carrying charges and insurance continue to pile up, it tends to force the price up," he explained. Although more physicians have permits than during previous years, the number of prescriptions per physician seems to be less and the gross volume is less, according to the commissioner's statement.

FOREIGN

Memorial to Andrew Balfour. — Friends and associates of the late Sir Andrew Balfour have decided to found a memorial to him and are asking his friends all over the world to contribute. When funds are available it is proposed to erect a simple memorial to him at the London School of Hygiene and Tropical Medicine, of which he was the first director, and with the remainder of the amount received to establish the Andrew Balfour Memorial Fund to help students to study at the school. Contributions should be sent to the Honorary Treasurer, Andrew Balfour Memorial Fund, London School for Tropical Medicine and Hygiene, Keppel Street, London, W. C. 1. Balfour died in January, 1931.

Course in Individual Psychology.—Dr. Alfred Adler is to be the director of a special three weeks' course in individual psychology, which will be given, June 20-July 10, at Semmering, near Vienna. Courses announced include: medical psychology; principles of individual psychology; problems in mental life; understanding human nature; training for the three tasks of life, social intercourse, profession and love and marriage; individual psychology and the school and what teachers, social workers and consultants should know of medicine. The main courses will be given during the first two weeks, and the third week will be devoted to special branches. Dr. Adler, Dr. Francis G. Crookshank, London, England, and Dr. Leonhard Seif, Munich, will be among the instructors. Application should be made before April 1. Inquiries may be addressed to Mrs. Sofie Lazarsfeld, Seilergasse 16, Vienna 1.

Society News.—Dr. John D. Rolleston gave the first of the twentieth series of Chadwick Lectures, February 18, at the Medical Society of London, on "Benjamin Ward Richardson, His Life and Work."——Mr. W. R. Bett addressed the Osler Club of London, January 22, on Viktor Hensen, who discovered in 1856 the glycogenic function of the liver independently of Claude Bernard. Prof. Leonard Findlay addressed the club, February 19, on the history of rickets.——An International Congress on Asthma will be held in Paris, June 4-5. Dr. Warfield T. Longcope, Baltimore, will represent the United States on the program. Information may be obtained from the secretary-general, Dr. Jean Galup, 19 Rue Auber, Paris. A second series of conferences on military medicine is to be held, June 23-25, in Liége, Belgium, under the auspices of the Office International de Documentation de Médecine Militaire. All medical officers of the land, sea and air forces are invited to attend. Lieut.-Col. Médecin Jules Voncken, Hôpital Militaire Liége, is in charge of registration.

International Congress for Light.—The second International Congress for Light will be held in Copenhagen, August 15-18. The subjects to be discussed are: the rôle of pigment in light biology, with Dr. Brody of France and Prof. Miescher of Switzerland as principal speakers; the systematic action of light in tuberculosis, with Sir Henry J. Gauvain, England, and Prof. Jesionek, Germany, speakers; and heliotherapeutic and climatologic research in relation to public health, with Prof. Walter Hausmann, Austria, and Prof. August Rollier, Leysin, Switzerland. Papers on other subjects to be read by members must be communicated to the secretary-general before April 1. Any member wishing to read a paper is requested to send a short summary in English, French or German to the secretary-general before May 1. The president of the congress is Dr. Axel Reyn, Copenhagen, and the chairman of the American committee is Dr. Alfred Hess, New York. In addition to Dr. Hess, William W. Coblentz, Ph.D., of the Bureau of Standards, Washington, D. C., and Ellsworth Huntington, Ph.D., Yale University, New Haven, will be among the speakers. The secretary-general is Dr. A. Kissmeyer, Finsen Institute, Strand Boulevard, Copenhagen.

The Control of Cerebrospinal Fever

The ministry of health has issued a report that reviews the present knowledge of cerebrospinal fever. During the past year there has been a definite increase of the disease in England and Wales. Though outbreaks described by Sydenham and others were probably due to the disease, its recognition is usually attributed to Vieusseaux of Geneva, who described an outbreak in 1805. Danielson and Mason recorded one in Massachusetts in 1806. Many epidemics have been described since, chiefly in Europe and North America, military camps and barracks being particularly affected. Excepting small outbreaks in London and Rochester in 1865 and in Bardney in 1867, England and Wales was comparatively free until the beginning of the present century. Limited outbreaks in country districts were followed in 1907 and 1908 by 1,238 cases in Glasgow, with 838 deaths, and at the same time 725 cases occurred in Belfast. In the years preceding the war the annual number of cases among civilians in England and Wales varied from 200 to 300. But in the war year of 1915-1917 the numbers were respectively 2,566, 1,306 and 1,465. Following demobilization the numbers fell year by year, until the antebellum level was attained in 1923. Since then there has been a gradual increase, which has also been observed in other countries of Europe. The increased prevalence among civilians during the war years coincided with the 4,238 cases and 1,928 deaths in the army at home in 1914-1918. In England, cases occur all the year round, but the greatest incidence is in the winter and spring. The heavier incidence in rural than in urban districts, described in the United States, has not been observed. The majority of cases occur among children under 5.

The means of control consist first in compulsory notification and provision of means of bacteriologic diagnosis by the ministry of health. If isolation and the best available treatment cannot be obtained at home, hospital treatment is to be at once offered. The closest and most accurate observation on the efficiency of the serums in use is considered desirable. As one hospital rarely has sufficient cases for investigation, the ministry is collecting all the evidence as to the results of serum treatment, both as to methods of administration and as to the nature of the serum used. The cooperation of health officers, hospital medical officers and physicians is invited, and blanks for this purpose are supplied by the ministry on application.

Malformations of the Perineum

At the Royal College of Surgeons, Sir Arthur Keith devoted his final lecture on "Malformations of the Human Body Considered from a New Point of View" to the perineum. He pointed out that in the latter half of the second month transformations are being effected at both ends of the alimentary tract. The mouth is being separated from the nasal cavity by growth of the palatal septums, separating the breath-way and the food-way. At the same period the cloaca is being transformed so as to give the bowel a passage separate from that for the kidneys and genital glands. All these developmental operations involve processes akin to the healing of wounds. If they fail, the aid of the surgeon becomes necessary. A palateless fetus, with persistent cloaca, reverts to a condition that prevailed in the highest vertebrates 250 million years ago and still exists in the amphibia. About a hundred million years later, reptile-like creatures in South Africa were assuming mammalian palates and presumably similar changes were occurring at the other end of their bodies. In the human fetus of the fifth week, when the wolffian body still serves as a kidney, the rectum and bladder join together high above the point at which the wolffian duct (vas deferens) terminates in the common cloacal passage. A few days later the renal (or ureteral) bud has sprung from the wolffian duct and the termination of the rectum has moved down on the common passage, so that it ends level with the termination of the wolffian duct. Before the end of the seventh week it has reached the site of the prostate and by the eighth week it has reached and fused with the cloacal membrane. It is usual to describe the separation of the rectum from the urogenital system as due to septal formation. But the terminal part of the developmental rectum is enveloped by a mass of rapidly growing embryonic tissue; the whole forms a migrating mass which carries the rectum along the cloaca until the surface of the perineum is reached. There is a mass movement of tissue of exactly the same nature as that which brings about the migration of the testis. The cloaca is not cleft; it passes into the service of the kidneys and genital glands.

The rectum may be arrested at any point of its three weeks' migration. It may open high in the bladder, but usually, if the cloacal anus persists, it opens into the prostatic urethra of the male or vulval cleft of the female, just below the hymen. Or it may cut its connection with the cloaca at any point in its descent and cease to grow. Hence it may terminate at any point between the rectovesical pouch and the perineum. The external anal depression may be formed or not. The better it is demarcated, the better the hope of finding the rectum low in the pelvis.

The migration of the rectum in the ancestry of mammals must have been as it occurs in man during the sixth to the eighth weeks of fetal development. The mechanism may be unknown, but the movement was connected with reproduction. With the appearance of reptiles took place a revolution in the methods of producing young. Long oviducts came into being, along which had to pass yolk-laden fertilized eggs, and there had to be intromission of spermatozoa within the cloaca. The lips of the cloaca underwent changes which helped to make the cloaca of the male serve as the intromittent organ. In early mammals the cloaca became, in the phraseology of Wood Jones, an intracloacal or implicate penis and then an external or explicate penis. In the lowest mammals—the monotremes—this change can be seen taking place. Clearly the passage for semen and urine could not serve the needs of the alimentary tract. Of the inner workings of the developmental movements there is no certain knowledge, but it can be surmised that they are brought about by growth-controlling substances formed in the developing genital glands. Dependence on them may be inferred from what happens as soon as the permanent anus is established. In the female the cloacal margins become the boundaries of the vulval cleft; the cloaca remains open, giving exit to bladder and vagina. In the male the margins of the cloacal orifice begin to unite at the margin of the anus to form the floor of the urethra. But if the testis is imperfectly developed this union fails at various stages, and hypospadias is produced.

Eliminating Street Noises

The injurious effects of noise, which was recently discussed in an editorial comment in The Journal, has also received attention in this country. The designing of a window to exclude, as far as possible, the noises of the street does not seem to have occurred to American builders. Mr. E. T. Fisk, managing director of Amalgamated Wireless (Australasia), Ltd., has designed a new type of window which, he asserts, has an efficiency of 75 per cent or over in deflecting street noises. A number of these windows have been fitted to offices and broadcasting studios in Sydney and Melbourne. The device has been scientifically tested in Britain. Light and air are not obstructed, but rain and dust are excluded. The window consists of a main frame into which are built subpanels or louvers, which can be turned outward at any angle required in any particular thoroughfare to deflect the noise. Inside the window are a number of sunblinds fitted on the louver principle, and the casement of the window is lined with fiber to absorb as much as possible of the remaining volume of sound that is able to get through the panels. For less sunny climates it is suggested that slips of glass on the louver principle could replace the inner sunblinds, used in the Australian tests, and would admit more light.

Illicit Drug Traffic

The Egyptian government's narcotics central bureau, in its report for 1931, shows that Turkey appears to have become an important center of illicit traffic, though the Turkish government is taking steps to deal with the matter. In Greece, again, traffickers are aided by the absence of provisions for the preventive arrest and detention of persons accused. Unfavorable comment is made on the number of cases in which members of Lloyd Triestino steamers figure as traffickers' agents. The most striking fact of the report is that whereas the number of drug addicts in Egypt decreased considerably last year, the number of traffickers increased. These effects seem to be due to one cause. There appears to be an increasing adulteration of the drugs, which increases the profits of the traffic and attracts more persons into it. On the other hand, the number of addicts is diminished, for they find that they can no longer afford to pay for the amount of drug necessary for the desired reaction. In 1930, 2,828 traffickers and 4,580 addicts were arrested; in 1931 the numbers were 4,327 and 2,882. The big development of the trade is shown by the amounts seized by the Egyptian customs and frontier guards; there was a total of more than 4,000 kilograms, while 11,649 kilograms was seized inside the country. It was found that 57 per cent of the addicts spent more than half their daily wage on drugs. A curiosity of the report is the instance of a Cairo contractor who paid his laborers in diacetylmorphine instead of money.

The Reflection of Ultraviolet Rays by Mirrors

J. Cluzet and T. Kofman, in a communication presented to the Société de biologie of Lyons, showed by means of the cadmium photo-electric cell that ultraviolet rays under 3,000 angstroms behave with metallic mirrors exactly like ordinary light. The slight differences in the frankness of the images produced by these mirrors correspond to important differences in the quantity of ultraviolet rays reflected. Glass mirrors, whether backed with a silver coating or not, are much inferior as reflectors of ultraviolet rays to metallic mirrors. With a glass 1 mm. thick, only the anterior surface reflects ultraviolet rays, all that part of the cone of rays that penetrates the glass being entirely absorbed. From two points of view, these results are applicable to actinotherapy. It would be advisable, in order to improve considerably the output of ultraviolet ray apparatus, to employ as reflectors genuine metallic mirrors in place of plates of aluminum insufficiently polished. Likewise, the laryngoscopic mirrors used for actinic treatment of tuberculous laryngitis should be as aplanatic as possible—made of nickel or steel but not of glass, since glass absorbs nearly all the ultraviolet rays that fall on it.

Technic of Parathyroidectomy

Professor Leriche, surgeon of Strasbourg, has made a special study of parathyroidectomy in diseases associated with hypercalcemia. In a recent article in the *Gazette des hôpitaux*, he gives the details of his surgical technic. He has performed this operation fifteen times—three times for polyarthritis, twice for Recklinghausen's disease, six times for scleroderma, once for spontaneous keloid, once for painful tumor of the spine, twice for circulatory disorders. No deaths or complications resulted. He always obtained a frank diminution of the hypercalcemia, amounting to one fourth or even one third. Leriche gives minute details of the technic he developed which is necessary to secure a good result; for, while the parathyroid is sometimes easy to find when located between the branches of the inferior thyroid artery, near their bifurcation, it is sometimes situated higher, or is even hidden by the capsule of the thyroid gland. The surgeon sometimes perceives, after the operation and the histologic examination, that he has removed only a lump of fat. Mr. Leriche advises, when the gland is not visible, being too high or concealed, to place a double ligature on the inferior thyroid artery and to dissect out a strip of thyroid tissue in which the gland will be included. The simple ligature of the thyroid artery often suffices to cause ischemia and to improve the hypercalcemia. But the results are more certain when one performs the two operations: the arterial ligature and the removal of the gland. The question as to whether it is sufficient to remove the parathyroid on one side alone is left open by Leriche. He does not think that double excision is useful except in serious cases of Recklinghausen's disease, in polyarthritis with ankylosis of long standing, and in advanced sclerodermas.

The Antituberculosis Dispensaries

The report published by Mr. Marcel Moine, in charge of the statistical service of the Comité national de défense contre la tuberculose, contains facts concerning the activity of the dispensaries in 1930 and the mortality from tuberculosis in France. The report shows that the number of dispensaries continues to increase, but that, at the same time, their work increases from year to year. This activity is expressed by 86,400 consultations, during which 1,088,875 examinations, some clinical and some radiologic, were made; 611,815 consulting patients were admitted in 1930, 251,867 of whom were tuberculous, while 160,091 bacteriologic examinations were performed in the laboratories that collaborate with the antituberculosis organizations; 61,107 patients have been admitted to the institutions for prophylaxis and treatment. The collaboration of the medical profession with the work of the dispensaries is becoming more extensive every day; 59,634 patients, in place of 46,801 in 1929, were referred in 1930 by the practicing physicians.

Transmission of Lymphogranulomatosis to the Monkey

Professor Levaditi, in collaboration with Ravaut and Cachera, injected into a monkey's brain pus from human lymphogranulomatosis. An emulsion from this infected brain inoculated under the preputial skin of a patient affected with dementia paralytica produced in him a typical bilateral inguinal adenopathy. An antigen prepared with this heated emulsion was employed to produce intradermal reactions in patients affected with genuine lymphogranulomatosis and in others affected with various suspected lesions. Reaction was constantly positive in the first and negative in the other cases (one case somewhat doubtful). The results with these reactions when human antigen was used were similar, thus establishing frankly the identity between experimental lymphogranulomatosis in the monkey and the same disease in man.

The Treatment of Pulmonary Gangrene

Prof. H. Vincent and Mr. Stodel presented recently, before the Academy of Medicine, accounts of their extensive experience in the treatment of pulmonary gangrene. They distinguished genuine gangrene with sphacelus of the pulmonary tissue from other putrid disorders of the lung, with which it is often confounded. The disease may be caused by many different micro-organisms, among which the anaerobes are prominent, especially B. fusiformis, B. ramesus and, more rarely, B. perfringens. The spirochetes are not the usual agents of pulmonary gangrene. They may be absent in the fatal and the benign forms. But Streptococcus viridans or hemolyticus is found frequently, and, in association with fusospirillary symbiosis, creates a special factor of gravity. One may encounter the pneumococcus, Bacillus coli, B. pyocyaneus, and especially the enterococcus. Vincent has treated pulmonary gangrene, since 1917, with polyvalent antigangrene serum, which he prepared in collaboration with Stodel. The mortality, leaving out of consideration the cases in which treatment was begun too late, is 16 per cent. But this serotherapy must be supplemented by arsphenamine treatment when an examination of the sputum shows the presence of spirochetes, although the arsphenamines if employed alone may be inadequate. If there are streptococci, antistreptococcus therapy is needed in addition, and more rarely antipneumococcus therapy. Prophylaxis in the form of oral hygiene is required of patients who cough and also of patients operated on, for all the micro-organisms found in pulmonary gangrene come from the buccal cavity, from which they are drawn into the bronchi in breathing.

Draft of a Law Regulating Medicinal Products

The constitution of the German *reich* fully recognizes the right of the national government to enact legislation regulating the preparation, manufacture and sale of medicinal products, but federal control of such matters has been to date exceedingly meager. A law that will control the manufacture of medicinal remedies, and also a systematic recapitulation and reorganization of the existing laws, are needed. The draft of a law pertaining to medicinal products has been presented, which is, however, in the nature of a skeleton law, containing the requisite definitions of terms, delimitations of the applicability, and the necessary provisions of a general nature, as well as statements concerning the range of authority of the federal government. A number of existing provisions have been recast in a different form, while for other matters, such as the supervision of production and the introduction of a test for certain medicinal products (vaccines, therapeutic and protective serums, arsphenamines, digitalis leaves) new provisions have been drafted.

The proposed law is the foundation on which is to be erected later the system of regulation, which will constitute the decisive content of the law, from the standpoint of practical utilization and scope. Precisely this form of the skeleton law constitutes one of the chief points of difference in the violent controversy that has developed with the various commercial interests—namely, preeminently the pharmaceutic industry. The draft of the provisions concerning enforcement, as the decisive part, must be awaited before any definitive attitude can be taken toward the proposed legislation. The draft as already published contains, above all, fundamental definitions; for example, of the terms "medicinal products," "disease," "malady" and "medicine." It is important that also measures for the prevention of pregnancy, if they are likely to be injurious to health, as well as measures for the interruption of pregnancy, are to be controlled by the law.

One of the important paragraphs contains the regulations concerning the manufacture and sale of medicinal products. The needs of the situation are to be the determining factors in the promulgation of regulations concerning manufacture and sale. It is peculiar that it is not the production of a single preparation that requires authorization but the establishment of a pharmaceutic manufacturing plant. Such authorization may not be given an industrial plant unless the owner furnishes proof that he has the necessary scientific knowledge to carry on such an enterprise in a satisfactory manner. The aim is to eliminate the production of injurious medicaments or such as are likely to deceive the consumer, without imposing more burdens than actually necessary on the manufacture of unobjectionable products. All parties concerned have, on the other hand, an urgent interest in seeing that concessions are conferred only on reliable producers. It is, for example, in no wise desirable that persons without scientific training shall interest themselves in the production of "specialties."

The number of medical specialties on the market in Germany varies in different reports, but the usual estimate ranges between five and six thousand. The state, the medical profession and the public are equally interested in the preservation of the pharmacy. It is the trustworthy dispensary of medicinal products.

Of course, trade in medicinal products that are known to be injurious to health is prohibited; for example, a tincture manufectured with methyl alcohol; likewise, the selling of medicine by pedlers, which is said to have become a common practice, is forbidden. It is important that regulations can be promulgated with regard to the collection, preparation, production, quality, testing, designation, packing, storing, transportation, prescribing and dispensing of medicinal products.

Whatever form the law shall assume, it will lead to a clarification of the complicated legal situation in the field of legislation pertaining to medicinal products and will furnish a broad basis for opposing with great energy the illegal traffic in medicinal products, which is eminently desirable, in order to provide our people in a rational and safe manner with the medicines and drugs that they need.

The fundamental demands—a responsible, scientifically trained director of a pharmaceutic manufacturing plant, declaration of the active ingredients, holding the producer responsible for the agreement of the declared ingredients with the actual composition, and the abolition of exaggerated or deceptive advertisements—will doubtless be realized in a generally satisfactory manner.

The law pertaining to the manufacture and sale of medicinal products aims, without placing any obstacles in the way of legitimate research and of the development of trade and commerce, to combat abnormal outgrowths and to erect a strong bulwark for the protection of public health.

Irradiation in Treatment of Exophthalmic Goiter

Since the influence of roentgen rays in producing a changed reactivity of the tissues has been known, successful attempts have been made to treat exophthalmic goiter by means of irradiation. Surgical intervention will attain its goal more quickly, whereas irradiation must be carried out for months. A number of studies on the subject (by Professor Schlecht and Dr. Hess, Krankenhaus Bethesda in Duisburg; Dr. Prüfer, Augusta Hospital, Berlin; Professor Halberstaedter, Charité Hospital, Berlin) were recently discussed in the *Münchener medizinische Wochenschrift*. They consider that one cannot decide, in principle, definitively for or against irradiation, but that the whole condition of the patient, and, above all, the manner in which he reacts to irradiation, must be taken into account.

It may occur that in especially sensitive patients poisonous substances will be eliminated from the pathologically changed thyroid gland. If a severe type of goiter is involved, one cannot be certain that irradiation will be successful. An exacerbation of the condition during the period of irradiation may not necessarily be due to that intervention; for the disease may progress in spite of irradiation. In any event, great care must be exercised in the choice of the patients to be irradiated. Hess and Schlecht recommend that an adequate ray dosage be applied and that the ray treatment be not given up too soon. The interval between the beginning of irradiation and definite improvement or cure ranges between three and twenty-four months, the average time being sixteen months. Improvement is usually evident about four weeks after the beginning of the irradiation, and continues more or less slowly but steadily. As a rule, one cannot speak of a satisfactory condition even after the lapse of four months, for the end of the period of action, and thus the peak of the improvement, is not reached until no objectively demonstrable manifestations and subjectively no, or only slight, symptoms are present. This method of treatment must be supported by an internal, dietary and medicamentous therapy. A diet of low protein content (especially as regards meat) but of high carbohydrates and fat content is recommended. If the condition is serious, the patient must remain in bed during the first weeks of treatment. The first series of irradiation is best carried out at a roentgenologic center. During the several series of irradiations careful attention must be paid to the protection of both mind and body, and to the strict observance of the prescribed hours of rest in bed.

Celebration of Medical Society's Centenary

The Ärztlicher Verein in Bremen celebrated, January 9, the hundredth anniversary of its existence. The commemorative address was delivered by the Munich clinician Prof. Friedrich von Müller, his subject being "Old Medical Books." At the memorial session, January 10, Professor Kirstein, the chairman of the society, gave an address in which he presented the need of an independent medical profession and of efficient methods of combating charlatanry. Of the 600 medical societies in Germany, the Bremer Verein is the fourth oldest, being antedated only by the societies of Lübeck, Donaueschingen and Hanover. The society has published an extensive study or history of public health activities, written by Tjaden, "Bremen und die bremische Aerzteschaft seit dem Beginn des 19. Jahrhunderts," which contains much valuable information in the fields of social hygiene and public health in general.

BELGIUM

Occupational Medicine in the Chemical Industry

Addressing recently the Société belge de médecine et de chirurgie du travail, Mr. Van Temsche discussed the organization of occupational medicine in the chemical industry. Occupational medicine is a rather new specialty the practice of which requires a thorough knowledge of physiology, pathology, occupational hygiene and social medicine. The nature of the work must be learned chiefly by experience, but the universities have created special chairs of hygiene and occupational medicine. The clinics of occupational medicine provide treatment for the workman; they provide for his rehabilitation, when necessary, and supervise the hygienic conditions of labor. The medical supervisor attached to the management of chemical manufacturing plants should coordinate the activities of the physician in the various plants. The latter should consider questions pertaining to the physiology of labor, the physical and psychologic selection of workmen, and the hygiene of labor; also questions pertaining to the pathology of labor, such as occupational diseases, first aid, and prevention of accidents and intoxications.

Medical Supervisors of Aid Societies

As the mutual aid societies enter more and more into collective bargaining with the medical syndicates, the medical supervisor becomes a necessity. Mr. Van Wilder discussed this question at the congress of the Fédération médical belge. The patient having the right to choose his physician, the mutual aid society, whose duty it is to pay for the treatment and the loss of time, must be entitled to exercise a supervising control over the insured and is not under obligation to place implicit trust in a physician that it has not selected. The medical supervisor of the mutual aid societies thus becomes an important personage in our professional life. He should possess qualities of the highest type: (1) recognized scientific ability, (2) long clinical experience, (3) an irreproachable professional reputation, assuring him of the esteem of his colleagues, and (4) a constant care to preserve the best professional ethics. The supervisor should renounce absolutely all outside medical and surgical practice, at least as regards the members of the mutual aid societies of which he is the inspector. This condition, which is so difficult to carry out in mutual aid societies, is nevertheless of fundamental importance. Following the presentation of this paper, the congress adopted the following conclusions:

The federated physicians wish to collaborate in the most frank and open manner in the organization of a worthy and honest system of social medicine. For that purpose, a double control is indispensable: that exercised by the sick benefit association over its members, and that exercised by the medical syndicate over every physician attending members of the mutual aid societies. If the sick benefit association desires a medical supervisor, he should comply with the following conditions: 1. He should be chosen by the medical syndicate in agreement with the sick benefit association. 2. He must not practice medicine among the members of the mutual aid societies, or at least not among the members of the societies to which he is attached. 3. He must not, under any circumstances, interfere in the relations between the patient and the attending physician. The technical control as affecting the relations between the attending physician and the patient will be entrusted by the mutual aid societies to the medical syndicates. The latter agree under contract to exercise a vigilant control, of their own initiative, and to defer to special demands of the medical supervisor of the mutual aid societies. The latter, in turn, must recognize and comply with the decisions reached by the national council on medical ethics. The congress rejected as improper and vexatious any other system that is in opposition to these principles.

The Congress on Natality

In November, Brussels was the headquarters for the Congrès de la natalité, which was devoted to the study of problems associated with the declining birth rate. This manifestation, due to the activity of a group of physicians interested in medical ethics, the Société médicale belge of Saint-Luc, reflects great credit on its promoters and cannot help but exert a good influence on the environment. In some twenty papers, presented, for the most part, by recognized authorities, all the aspects of the vast problem were considered. Special mention may be made of the eugenic point of view, which was presented by Drs. L. Vervaeck and F. Daubresse. The former, considering the problem of the birth rate from the eugenic point of view, holds that the solution depends on the ensemble of measures favoring the biologic quality of the children procreated, as based on certain scientific notions pertaining to physiologic and pathologic heredity. All legal intervention is for the present premature, and all compulsory applications of eugenics, including sterilization of abnormal persons, are unjustified. On the other hand, the voluntary prenuptial medical examination, when the right of privileged communication is preserved, the measures adopted against infectious diseases and intoxication, and the aid to abnormal persons in the sense of amelioration, help to solve adequately many extremely difficult cases that at first sight appear to be unsolvable.

Mr. Daubresse, analyzing the eugenic methods and their scientific and moral value, pointed out that eugenics has its positive side, which furthers the procreation of healthy families, and a negative side tending chiefly to prevent, either by sterilization or by segregation, the reproduction of defectives. He denounced the wrong process of selection commonly brought about by birth control, but, for weighty reasons, approved taking advantage of the agenesic period of women.

Professor Schockaert and Dr. De Guchteneere treated, respectively, the dangers of abortion and of neomalthusianism for the female organism, and the pathologic conditions resulting from contraception, subjects almost identical in their scope and purpose, but the different forms of which serve to strengthen the convictions that are reached: the exceedingly high mortality resulting from abortion (seven times greater than from childbirth) and physical morbidity from infection and secondary sterility owing to loss of hormones, from the development of cancer and fibroma, and from mental disease of unsuspected character, all penalties levied by nature against those who abandon the primordial function of their being.

Accidents from the Use of Chromium

Addressing the Société belge de médecine et de chirurgie du travail, Dr. Langelez discussed recently accidents due to the use of chromium. He took up first certain general chemical ideas pertaining to chromium and its compounds. He then explained the qualities which cause that metal to be valued by reason of numerous industrial applications. In Belgium, workmen are exposed in the chemical industries to accidents from the use of chromium (manufacture of bichromates) and in tanning and electrolytic processes. After explaining the technology of various industries employing chromium, Langelez presented the results of an inquiry recently made in Belgium. In factories producing bichromates, of 130 workmen examined, 59 presented lesions of the skin, and 53 lesions of the nose; in the tanneries, in 104 workmen examined, 23 lesions of the skin and 10 of the nose were noted, and in factories making electrolytic use of chromium, in 47 workmen 32 lesions of the skin and 16 of the nose were observed. Industry does not present generalized injuries due to the use of chromium. The local injuries are of three different types: (1) skin lesions presenting extremely polymorphous aspects (eczema, acne, edema, warts, burns, cicatrices, cracks in the skin), and especially in the form of perforations of the skin (*trous de chrome*); (2) eye lesions (traumatic or tattooing of the cornea), and (3) lesions of the nose, located chiefly at the site of Jacobson's organ and comprising three stages—usually successive: irritation atrophy of the mucous membrane, ulceration, and perforation of the septum.

Dr. Langelez explained the prophylactic and curative treatment of these various special lesions, which, in some cases, may cause loss of earning power. He described also the hygienic measures to be employed by industrialists and the methods of individual prophylaxis that should be observed by the workmen.

Scheme for Medical Service for the Middle Class

Conditions of medical practice and especially of public hospital service in Australia are fast reaching an impasse. Owing to the financial depression, patients are attending in increasing numbers at the public hospitals, which, to make matters worse, have suffered a reduction of income consequent on the decrease in private subscriptions and the reduction of government grants. Hospital managing boards are desperately striving to make up their deficiencies. Contributory schemes whereby, for 6d a week, subscribers receive free hospital and medical service are attractive to hospital managements, but they have the grave disadvantage that no payment is made to the medical men for services rendered. At present, the combined overdrafts of seven public hospitals in Melbourne amount to £196,000. It is felt quite definitely that the public hospitals for the present must revert to that service for which they were originally created—a service to the indigent—financed by charitable gifts from the community.

In order to cater to that growing social group which is unable to pay full private fees for medical service and to prevent exploitation of the medical profession, it is proposed to establish an organization, controlled by the British Medical Association, which would offer to the people, particularly in the industrial suburbs, a means whereby they can insure against the requirement in the time of sickness of medical and nursing service and of pharmaceutic supplies.

The scheme will be in the nature of a voluntary insurance. It is proposed to charge a regular rate plus a definitely reduced charge for each service rendered. The scheme will be so arranged that freedom of choice will be given to the subscriber as regards his general practitioner, his consultant, his surgeon, his hospital and his chemist.

For a weekly premium varying from 5d for a single male or female under 21 years, to 1/- for a subscriber and wife and more than two children, the subscriber receives domiciliary medical service at a service charge of 3/6 per visit or consultation (the ordinary fee being from 10/6 to £1/1/-), investigational services—pathologic or roentgenologic (5/- service fee) and pharmaceutic services (service fee half rate per prescription). In country districts the domiciliary service fee may need to be increased, and a mileage charge made for distances over two miles. A separate contract provides nursing and hospital services, consulting and specialists services for a fee of 9d per week or 39/- per year. This will provide cash benefits to subscribers: hospital expenses £2 per week, consultant and specialist service—surgical operations (major) up to £9, obstetric fee £3/3/-, anesthetic, £1/1/-. In each district there would be a bureau which would act as the local administrative office of the scheme and at that office every applicant for public hospital treatment (apart from emergency) would be submitted to an investigation of his financial status.

A central hospital bureau would be established which would have a current knowledge of hospital beds available in the district for the various categories of cases. It is proposed ultimately to eliminate the private nursing home and establish, instead, self-supporting hospitals designed to accommodate subscribers to the scheme.

In order to be eligible to benefit from this scheme, subscribers must have an annual income of less than £208 in the case of the single man or woman, and less than £312 for a married man, the limit being raised by £25 for each child.

This scheme has aroused considerable interest among the medical profession of Australia, and it is considered that, with minor alterations, it will be extensively adopted. The scheme is the culmination of years of discussion and consideration, and provides the first serious attempt to provide a complete private medical service for the lower middle class. The acceptance of this scheme by the public will be watched with considerable interest.

The Australasian College of Surgeons

The Council of the Royal College of Surgeons of England is presenting a hand-wrought and chiseled silver mace to the Royal College of Surgeons of Australasia. The staff is decorated with a pattern of English roses, Australian wattle and New Zealand ferns, and it is inscribed with the names of the twenty-four members of the council for the present year. The total weight of sterling silver is 189½ ounces troy, and the length is 3 feet 10⅜ inches. The mace will be presented to the Australasian body when Lord Moynihan visits Australia this year.

Under the will of the late Dr. Gordon Craig, the Royal Australasian College of Surgeons ultimately will benefit to the extent of about £40,000. Dr. Craig was a founder of the college and a member of the council from the time of its inception. The sum bequeathed to the college will be held in trust. One half of the income from it will be devoted to the promotion of research in surgery, and the remainder will be used to assist young graduates of exceptional ability and promise to take postgraduate work in surgery.

The Medical Press of Australia

Considering the relatively small population in Australia, it is well supplied with medical periodicals. The *Medical Journal of Australia*, published weekly in Sydney, is the official organ of all British Medical Association news and reports. The *Journal* receives all papers read at official meetings of branches and also publishes original research contributions by Australian medical scientists. It has recently added to its usefulness by publishing a series of special articles on diagnosis contributed at the request of the editor by Australian authorities in various branches.

The *Journal of the Cancer Research Committee* of the University of Sydney, published monthly, has as its aim the education of the general practitioner in cancer diagnosis and treatment; it records the developments in the organization of cancer treatment in New South Wales and also publishes research work done under its egis.

The *Melbourne Hospital Clinical Reports* publishes quarterly some of the excellent papers read at clinical meetings and makes a special feature of digests of the hospital records dealing with various subjects.

The *Australian and New Zealand Journal of Surgery*, published monthly as the official organ of the Royal Australasian College of Surgeons, deals mainly with research in surgery and surgical pathology. It is considered that Australia is too small to justify any other specialty publishing its own journal.

A recent arrival in the periodical field is the *General Practitioner*. In this journal, research work has no place; proceedings of societies are excluded. It is a monthly postgraduate course. The extent of its circulation is an index of its popularity among the group of practitioners for whom it is specifically intended.

The department of health of the commonwealth issues a small periodical entitled *Health*, which is now mainly an official circular. An educational type of journal is the *Health Bulletin*, published by the Victorian Department of Public Health.

Statistics of Private Obstetric Practice

An analysis of 2,000 accurate case records collected by the obstetric section of the Queensland Branch of the British Medical Association showed a maternal mortality rate of 0.4 per cent. The rate for Australia as a whole for 1930 was 0.529 per cent. The puerperal morbidity rate according to British Medical Association standards was 7.3 per cent. The most frequent abnormality of presentation was occipitoposterior, 8.8 per cent; this rate included 2.7 per cent who were delivered in that position. There were 2.9 per cent breech presentations, 0.1 per cent face, and 0.05 per cent brow. Prolapse of the cord occurred in 0.45 per cent and hydramnios in 0.35 per cent.

Under the heading of abnormal labor, placenta praevia occurred nine times (0.4 per cent) with the loss of only one mother. The antepartum hemorrhage rate was 0.8 per cent and the postpartum rate, 1.9 per cent. Although 6.8 per cent had albuminuria, only 0.6 per cent developed eclampsia. Pyelitis occurred in 1.7 per cent.

The fetal mortality was 3.3 per cent, made up of the combined rates of macerated fetuses and 2.3 per cent stillbirths. Plural births occurred in 1.2 per cent of the series.

Lacerations of the perineum occurred in 25.9 per cent of the series, made up as follows: first degree, 16.2 per cent; second degree, 8.1 per cent; third degree, 0.2 per cent, and episiotomies, 1.3 per cent.

As regards the environment of the delivery in its relation to puerperal morbidity, it was found that 7.5 per cent of those attended in maternity homes were morbid, 6.5 per cent in general hospitals and only 4.5 per cent in the group that were delivered at their homes. Consideration, however, must be given to the tendency for difficult cases to be attended in a hospital. There were 23 per cent instrumental deliveries with a morbidity rate of 10.2 per cent. Of the patients who were morbid in the puerperium, 2.6 per cent of the total series were mild cases, 1.8 per cent had breast inflammation and congestion, 0.9 per cent had sapremia, and only 0.3 per cent developed severe sepsis.

TURKEY

(From Our Regular Correspondent)

Ankara, Feb. 16, 1932.

Antihookworm Campaign in the Black Sea Region

The eradication of malaria, syphilis, tuberculosis and trachoma was the chief public health problem before the World War. Another serious problem has presented itself as an outcome of the war, toward the end of which reports came from the Black Sea region that hookworm was threatening to become a menace. Practically nothing was known about the existence of hookworm in Turkey until that time. The few isolated cases that had come under observation before had been accidentally discovered in natives from Mesopotamia, the Yemen and the Hejaz who were undergoing treatment at the Istanbul city hospitals for some other disease. Twice in 1914 and 1915, hookworm had been discovered in the stools of inmates of the army hospital at Kuleli on the Bosphorus. About a year later, Prof. Neshat Omer reported that among more than 1,000 laboratory tests made at the Red Cresent Hospital in Palestine four cases of infestation with Ancylostoma duodenale had been diagnosed.

The postwar publications of Prof. Tevfik Salim Pasha, Akil Muhtar and others concerning Necator americanus in natives from the Black Sea region resulted in an investigation at the hospital laboratories in the provinces, which plainly demonstrated that hookworm was confined to the Black Sea region. It was decided, therefore, to organize an antihookworm campaign in the Rize province in the southwestern part of the Caucasus, where the climate and living conditions favor the spread of the disease.

In 1930, the ministry of health and social assistance asked Dr. Ziya, assistant professor of bacteriology at the Haydar Pasha medical school, to make an investigation there with the aid of a field laboratory and four sanitary inspectors. After a year's work, Dr. Ziya reported that the conditions were as follows:

The laboratory tests made in the different communities of the Rize province revealed a high incidence in the Hopa district, and antihookworm activities were begun there first. By the end of February, 1930, in the Rize province, 5,989 persons had been examined, with the result that infestation was discovered in 3,096 persons, or 51.6 per cent. Though 50 per cent may be taken as the average, in some communities the index of infestation was as low as 41 per cent and in others as high as 76 per cent. The distribution of the infestation varied with different family groups. Either all or a great majority of the members of certain families were involved, while in certain other families there was no infestation. This may seem paradoxical, but it is explained by the particular living conditions of these communities. The microscopic examinations did not show any marked difference as far as sex and age were concerned. The accompanying table shows the result of 3,799 examinations.

Incidence of Infestation

Age	Number of Stools Examined	Presence of Eggs	Absence of Eggs	Per Cent
1-10 years.........	1,126	597	529	53.1
11-20 years.........	1,089	576	513	52.8
Above 20 years.....	1,584	859	725	54.2
	3,799	2,032	1,767	

In his study of the adult parasites, Dr. Ziya has invariably found Necator americanus but never Ancylostoma duodenale. If parasites are found in large numbers, the eggs are numerous also, but the eggs were not always found at once, so in a number of cases three or more specimens had to be produced from one person. As it would have been too time consuming to make more than one examination per person, treatment was prescribed for everybody when the egg index in a community approached 50 per cent. From ten to fifteen days after administration of the anthelmintic, the stools of persons found infected previous to treatment were reexamined.

By the end of February, 1930, 500 persons had been treated. Laboratory examination following treatment revealed, however, that in 8.6 per cent eggs were still present in those persons whose stools had at the previous examination contained numerous eggs. After a second treatment, eggs were still present in 1 per cent.

In the beginning of the campaign a mixture of carbon tetrachloride and oil of chenopodium was used, but as symptoms of intolerance were observed, the use of oil of chenopodium was abandoned and the treatment continued with pure carbon tetrachloride only, the purity of the product being ascertained previously at the Ankara chemical laboratory. One dose of the tetrachloride in water was administered to 1,201 persons, from 0.1 to 0.15 cc. to each year of age for children, and a maximum dose of 2 cc. for adults. In 20 per cent of these persons, violent headache and drowsiness was observed, lasting from six to twelve hours, but as long as forty-eight hours in some cases. In an 8 year old child, vomiting and violent pain in the abdomen appeared on the day following the administration of the medicine, and the child died three days later though everything was tried to avert such an outcome. Dizziness with disturbed eyesight but without headache was present in quite a number of cases. The method of administration therefore was changed to the giving of two doses in solution and two hours later magnesium sulphate. Five hundred persons have had this treatment, and in 1 per cent of them dizziness and fainting was being observed within from one to two hours; in 5 per cent there was headache accompanied by drowsiness, and in another 5 per cent these symptoms were accompanied by an elevation of temperature to 99.5 F.

To eliminate these undesirable results, the dose of tetrachloride was decreased to 1.5 cc. for adults and from 0.1 to 0.2 cc. as the maximum dose for children. No important untoward symptoms were observed with the latter dosage, but in from 2 to 3 per cent of the persons treated slight dizziness was present.

The examination of stools on a large scale in the Rize province revealed that the eggs of Ascaris, Trichocephalus and Oxyuris vermicularis often existed side by side with those of Necator americanus, the eggs of Ascaris being found in 28 per cent and the eggs of Trichocephalus in 6 per cent. It appears that Oxyuris vermicularis and Ascaris also yield to carbon tetrachloride, as they were seen occasionally, but after treatment the eggs of Ascaris and Trichocephalus were invariably present in much greater numbers. It is almost certain that before the World War hookworm did not exist in the Rize province. It is believed that hookworm was introduced into the Rize province by Russian laborers engaged there in road construction during the time the province was being occupied by the Russian army toward the end of the war. The southern part of the Rize province is mountainous, the coast has fertile valleys, and there is an abundant rainfall. There are numerous springs. The humidity of the soil is high. The province is densely populated, and agriculture is the main occupation. The privies in rural communities are defective and insufficient in number. The humidity of the soil, its pollution with different kinds of manure, and the fact that the people spend the greater part of the year in the fields all contribute to the wide spread of the disease. Since the beginning of the antihookworm campaign, sanitary privies have been installed and instruction has been given the population as to the prevention and mode of transmission of the disease. The indiscriminate use of manure on fields, the use of contaminated wells for their watering and the pollution of drinking water have been strictly prohibited. The area to be covered by the antihookworm campaign is large; its sphere will gradually be widened.

Marriages

ROBERT BURNS SANDERSON, Crown Point, Ind., to Miss Alpha Lorraine Rodenberger of Springfield, Ill., Dec. 25, 1931.

GEORGE R. DILLINGER, French Lick, Ind., to Miss Margaret Dowden of Jeffersonville, Dec. 27, 1931.

WILLIAM BAIRD STUART, Carlisle, Pa., to Mrs. Hanne Daube Berk of Germany, January 7.

THEODORE R. KOENIG, Edgewood, Pa., to Miss Helen Clayson of Pittsburgh, January 1.

JAMES ALFRED GOOCH to Miss Lelia Watkins Stacy, both of Richmond, Va., January 4.

MATHEW GRISWOLD, JR., to Miss Charlotte Brevillier, both of Erie, Pa., Dec. 22, 1931.

RANDALL B. HAYES, Jersey Shore, Pa., to Miss Sara Bitler of Millville, Dec. 8, 1931.

ROBERT IRVING HILLER to Miss Ruth Krome, both of Milwaukee, January 3.

RICHARD S. BECHK, Cleveland, to Miss Josephine Dohman, recently.

Deaths

David Clark Thompson ⊕ Bloomfield, N. J.; University and Bellevue Hospital Medical College, New York, 1911; fellow of the American College of Surgeons; served during the World War; on the staffs of the Mountainside Hospital, and St. Vincent's Nursery and Babies' Hospital, Montclaire and the Essex County Hospital for Contagious Diseases, Belleville; aged 46; died, in February, of heart disease, while aboard the *S. S. Pastores*, bound for the West Indies.

John Milton Allen ⊕ St. Johnsbury, Vt.; University of Vermont College of Medicine, Burlington, 1890; Bellevue Hospital Medical College, New York, 1891; member of the New England Surgical Society and fellow of the American College of Surgeons; attending surgeon to the Brightlook and St. Johnsbury hospitals, St. Johnsbury, Orleans County Memorial Hospital, Newport, and consulting surgeon to the Littleton (N. H.) Hospital; aged 64; died, February 9.

Charles Whitney Page, Hartford, Conn.; Harvard University Medical School, Boston, 1870; member of the Connecticut State Medical Society, Massachusetts Medical Society, American Psychiatric Association and the New England Society of Psychiatry; aged 86; died, February 16, of chronic myocarditis and acute bronchitis.

Arthur John Weaver ⊕ Muscatine, Iowa; Bennett College of Eclectic Medicine and Surgery, Chicago, 1895; past president of the Muscatine County Medical Society; fellow of the American College of Surgeons; member of the state board of health; on the staff of the Bellevue Hospital; aged 66; died, March 1, in a local hospital.

Sydney Henry Smith, Salinas, Calif.; John A. Creighton Medical College, Omaha, 1909; member of the California Medical Association; aged 52; died, Dec. 17, 1931, in the University of California Hospital, San Francisco, of carcinoma of the left suprarenal, with metastases to the lungs, liver and vena cava.

John H. Bailey, Clyde, Texas; Memphis (Tenn.) Hospital Medical College, 1895; member of the State Medical Association of Texas; aged 61; died, February 13, in a hospital at Abilene, of injuries received when the automobile in which he was driving was struck by a train.

Henry B. Luhn ⊕ Spokane, Wash.; University of Pennsylvania School of Medicine, Philadelphia, 1891; fellow of the American College of Surgeons; surgeon to the Sacred Heart Hospital; aged 64; died, February 10, in Moscow, Idaho, of myocarditis and edema of the lungs.

Charles Sleeper Gilman, Lakeport, N. H.; Baltimore Medical College, 1896; member of the Massachusetts Medical Society and the American Proctologic Society; aged 58; died, January 20, in the Laconia (N. H.) Hospital, of gallstones and cholecystitis.

George Albert Haveman, Columbus, Ohio; Miami Medical College, Cincinnati, 1905; member of the Ohio State Medical Association and the Associated Anesthetists of the United States and Canada; aged 50; died suddenly, February 20, of heart disease.

Albert Ferdinand Beddoe, Dallas, Texas; Memphis (Tenn.) Hospital Medical College, 1894; formerly professor of diseases of children, Baylor University College of Medicine; aged 78; died, January 27, of diabetes mellitus and pulmonary edema.

Charlotte Fairbanks, St. Johnsbury, Vt.; Woman's Medical College of Pennsylvania, Philadelphia, 1902; fellow of the American College of Surgeons; served during the World War; aged 59; died, February 13, in Framingham, Mass., of brain tumor.

William C. Canfield, Newton, Mass.; University of Pennsylvania School of Medicine, Philadelphia, 1888; member of the Rhode Island Medical Society; aged 74; died, February 8, in the Westborough (Mass.) State Hospital, of arteriosclerosis.

Louis Schapiro, Bangkok, Siam; George Washington University Medical School, Washington, D. C., 1907; representative of the International Health Division of the Rockefeller Foundation; aged 45; died, February 4, of pulmonary embolism.

Abijah Orange Buck ⊕ Elizabeth, N. J.; Hahnemann Medical College and Hospital of Philadelphia, 1890; served during the World War; on the staff of the Alexian Brothers' Hospital; aged 62; died, February 15, of heart disease.

Theodore J. Schweer ⊕ Beardstown, Ill.; Rush Medical College, Chicago, 1897; formerly postmaster; president of the sanitary district and for five years president of the school board; aged 62; died, February 17, of pneumonia.

Charles Homer Holaday, Detroit; Washington University School of Medicine, St. Louis, 1911; aged 51; died, February 12, in a hospital at Miami, Fla., of acute hemorrhagic pancreatitis, chronic hypertension and arteriosclerosis.

George Calvin Skinner, Hamilton, Ohio; Miami Medical College, Cincinnati, 1879; past president of the Butler County Medical Society; formerly member of the board of education; aged 75; died, January 21, in the Mercy Hospital.

Otta Clarence O'Kell, Excelsior Springs, Mo.; Northwestern Medical College, St. Joseph, 1893; member of the Missouri State Medical Association; served during the World War; aged 62; died, February 2, of heart disease.

James M. Merryman, Columbus, Ohio; University of Wooster Medical Department, Cleveland, 1870; Civil War veteran; formerly member of the state legislature; aged 87; died, February 8, of arteriosclerosis and senility.

Frederick W. Bromley, Whitewater, Wis.; University of Pennsylvania School of Medicine, Philadelphia, 1881; member of the State Medical Society of Wisconsin; aged 80; died, February 4, in Palmyra, of cerebral hemorrhage.

Ernest Gustav Nathaniel Tillmanns, Los Angeles; Rush Medical College, Chicago, 1914; member of the California Medical Association; served during the World War; aged 50; was killed, January 25, in an airplane accident.

Robert Merritt Davis, Birmingham, Ala.; Tulane University of Louisiana Medical Department, New Orleans, 1895; member of the Medical Association of the State of Alabama; aged 57; died, February 9, of heart disease.

James Heustis Jones ⊕ Camden, Ala.; Tulane University of Louisiana School of Medicine, New Orleans, 1901; past president and secretary, Wilcox County Medical Society; aged 54; was found dead in bed, February 2.

Willis Warren Dean, Sioux City, Iowa; Medical Department of Omaha (Neb.) University, 1895; member of the Iowa State Medical Society; formerly police surgeon; aged 59; died, February 13, in a local hospital.

John Cady Parsons ⊕ Marcellus, N. Y.; University of the City of New York Medical Department, 1891; on the staff of the Crouse-Irving Hospital, Syracuse; aged 71; died, February 24, of cerebral thrombosis.

Robert Cornelius Fleming, Louisville, Ky.; College of Physicians and Surgeons, Baltimore, 1900; served during the World War; aged 54; died, February 12, in the Methodist Episcopal Deaconess Hospital.

Frank Lyall Griswold, Mazomanie, Wis.; Milwaukee Medical College, 1905; member of the State Medical Society of Wisconsin; served during the World War; aged 54; died, February 11, of heart disease.

James Glynn Gregory, Norwalk, Conn.; College of Physicians and Surgeons in the City of New York, 1868; member of the Connecticut State Medical Society; bank president; aged 88; died, February 1.

Herbert Cline Turrell, Durango, Colo.; Colorado School of Medicine, Boulder, 1902; member of the Colorado State Medical Society; aged 55; died, January 12, in a hospital at Pasadena, Calif.

Matthew H. Blackburn, Princeton, Ill.; State University of Iowa College of Medicine, Iowa City, 1889; member of the Illinois State Medical Society; aged 70; died, February 8, of angina pectoris.

Thomas J. Hardison, Carters Creek, Tenn.; University of Nashville Medical Department, 1880; member of the Tennessee State Medical Association; aged 75; died, January 30, of angina pectoris.

Albert Lawrence Thompson, Makanda, Ill.; St. Louis College of Physicians and Surgeons, 1898; aged 54; died, February 5, in the Holden Hospital, Carbondale, of carcinoma of the throat.

Joseph Ambrose Dittmore ⊕ Chicago; Bennett Medical College, Chicago, 1915; on the auxiliary staff of the Alexian Brothers' Hospital; aged 55; died, February 15, of cerebral hemorrhage.

Jed Burt Freund, Butte, Mont.; University of Michigan Medical School, Ann Arbor, 1900; on the staff of St. James Hospital; aged 57; died, February 3, of chronic nephritis and myocarditis.

Thomas Adolph Heath, Shiloh, Miss.; Hospital College of Medicine, Louisville, Ky., 1881; member of the Mississippi State Medical Association; aged 77; died, January 17, of lobar pneumonia.

Edward Thomas Craney, Orlando, Fla.; Medico-Chirurgical College of Philadelphia, 1910; member of the Florida Medical Association; aged 54; died, February 22, of pneumonia.

George W. Washburn, Star City, Ind.; Eclectic Medical Institute, Cincinnati, 1894; formerly county coroner and county health commissioner; aged 66; died, January 31, of cerebral embolism.

Robert Groves McCarthy, Chicago; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1899; aged 55; hanged himself, February 12.

Elizabeth C. Kane ⊕ Memphis, Tenn.; University of Nashville Medical Department, 1898; aged 55; died, February 10, in the Union Memorial Hospital, Baltimore, of carcinoma of the colon.

Fred Hill Fowler ⊕ Joliet, Ill.; Medical Department of Hamline University, Minneapolis, 1897; member of the Kansas Medical Society; aged 57; died, February 15, of an injury to the spine.

Virgil Maro Dow, New Haven, Conn.; Yale University School of Medicine, New Haven, 1864; Civil War veteran; aged 98; died, February 19, of cerebral hemorrhage and arteriosclerosis.

Louis Proudfit, Osceola, Ind.; Medical College of Indiana, Indianapolis, 1902; member of the Indiana State Medical Association; aged 55; died suddenly, February 2, of heart disease.

Germanus J. France, Baltimore; Maryland Medical College, Baltimore, 1911; formerly county coroner; aged 42; died, February 9, of cerebral embolus and vegetative endocarditis.

Anna K. B. Hyden, Alcester, S. D.; Keokuk (Iowa) Medical College, 1897; member of the South Dakota State Medical Association; aged 58; died, February 2, of cerebral hemorrhage.

Joseph Franklin Griggs ⊕ Tacoma, Wash.; University of Pennsylvania School of Medicine, Philadelphia, 1895; aged 60; died, February 9, of a skull fracture received in a fall.

Francis Brinton Jacobs ⊕ West Chester, Pa.; University of Pennsylvania School of Medicine, Philadelphia, 1900; aged 57; died suddenly, February 11, of cerebral hemorrhage.

Washington La Fayette Doss, Columbus, Miss.; University of Nashville (Tenn.) Medical Department, 1890; aged 65; died, January 22, in Crawford, of chronic endocarditis.

William Potter Langworthy, Watch Hill, R. I.; College of Physicians and Surgeons in the City of New York, 1876; aged 80; died, Dec. 17, 1931, in Daytona Beach, Fla.

Charles Fredrick Hera, New Richmond, Ohio (licensed, Ohio, 1896); member of the Ohio State Medical Association; aged 75; died, February 2, of cerebral hemorrhage.

Joseph Arnald Denman ⊕ Brackettville, Texas; Tulane University of Louisiana Medical Department, New Orleans, 1901; aged 59; died, February 12, of heart disease.

Robert A. Wallace ⊕ New Castle, Pa.; Miami Medical College, Cincinnati, 1877; on the staff of the New Castle Hospital; aged 76; died, February 6, of heart disease.

Joseph Frank Chretien, New Orleans; Tulane University of Louisiana Medical Department, New Orleans, 1890; formerly a druggist; aged 69; died, December 17.

Clarence E. Exline, Canton, Ohio; Ohio Medical University, Columbus, 1897; served during the World War; aged 60; died, February 17, of pernicious anemia.

Jacob Paul Stroman, McClellanville, S. C.; University of Georgia Medical Department, Augusta, 1885; aged 68; died, January 30, of heart disease and nephritis.

Michael Joseph Brennan, McSherrystown, Pa.; Temple University School of Medicine, Philadelphia, 1919; aged 39; died, February 4, of cerebral hemorrhage.

William Lincoln Bates, Jamestown, R. I. (licensed, Rhode Island, under the Act of 1895); aged 77; died, January 10, of chronic myocarditis and senile debility.

George Wesley King, South Point, Ohio; Ohio-Miami Medical College, Cincinnati, 1910; member of the county board of health; aged 57; died, January 6.

John Martin Weekley, Ulmer, S. C.; Medical College of the State of South Carolina, Charleston, 1860; aged 94; died, January 25, of hypostatic pneumonia.

John Bernard Plent ⊕ Cleveland; University of the City of New York Medical Department, 1891; aged 76; died suddenly, February 16, of heart disease.

William Jeremiah Woodlin ⊕ Columbus, Ohio; University of Michigan Medical School, Ann Arbor, 1895; aged 55; died, February 9, of heart disease.

Samuel James Staples, Bow Island, Alta., Canada; University of Toronto Faculty of Medicine, Toronto, Ont., 1905; died recently, at Medicine Hat.

Charles F. McLain, Calhoun, Ga.; Atlanta Medical College, 1895; member of the Medical Association of Georgia; aged 64; died, Dec. 26, 1931.

Carey Wiley Kendall, San Gabriel, Calif.; Hospital College of Medicine, Louisville, Ky., 1898; aged 63; died, Dec. 30, 1931, of heart disease.

John Haymaker Service, Philadelphia; Jefferson Medical College of Philadelphia, 1889; aged 75; died, February 11, of suppurative prostatitis.

Robert Lee Dowell, Chillicothe, Mo.; University Medical College of Kansas City, 1893; aged 64; died, January 30, of cerebral hemorrhage.

Eugene H. Levering ⊕ Stroudsburg, Pa.; University of the City of New York Medical Department, 1893; aged 63; died, February 10.

Paul B. de La Barre, Port Clinton, Ohio; Western Reserve University Medical Department, Cleveland, 1887; aged 80; died, Dec. 8, 1931.

James W. Hensley, Dewville, Texas; University of Tennessee Medical Department, Nashville, 1888; aged 67; died, Dec. 27, 1931.

Charles Benell, Diamond, Ind.; Medical College of Indiana, Indianapolis, 1889; aged 65; died, January 30, of cerebral hemorrhage.

Francis Wood Shaw, Vancouver, B. C., Canada; University of Toronto Faculty of Medicine, 1879; aged 77; died, January 3.

Walter Tisdale, Simcoe, Ont., Canada; Faculty of Medicine of Trinity College, Toronto, 1877; aged 76; died, Dec. 23, 1931.

Ezekiel Grant Dilworth, New York; Baltimore Medical College, 1895; aged 68; died, February 11, of coronary thrombosis.

Lawrence R. Brown, Sharon, Ga.; University of Georgia Medical Department, Augusta, 1888; aged 69; died, Nov. 26, 1931.

William Calhoun Dawson ⊕ San Francisco; University of California Medical Department, 1907; aged 51; died, Nov. 13 1931.

Homer Michener, Wichita, Kan.; Eclectic Medical Institute, Cincinnati, 1890; aged 68; died, January 4, of myocarditis.

Miles D. Baker, Carbondale, Ill.; Medical College of Ohio, Cincinnati, 1875; aged 78; died, in February, of angina pectoris.

Angela B. Farley, Cincinnati; Miami Medical College, Cincinnati, 1906; aged 56; died, February 10, of carcinomatosis.

Gustave Tedtman, Chicago; National Medical University, Chicago, 1897; aged 67; died, February 10, of heart disease.

William Herman Stone, Wilder, Tenn. (licensed, Tennessee, 1914); aged 45; died, February 8, of heart disease.

David H. Funderburk, Lancaster, S. C.; Maryland Medical College, Baltimore, 1904; aged 66; died, Dec. 4, 1931.

William Irwin Taylor, Port Credit, Ont., Canada; T. Medical College, Toronto, 1898; died, Nov. 24, 1931.

Bureau of Investigation

NORMAN BAKER VS. THE AMERICAN MEDICAL ASSOCIATION

The Jury Declares the Association Not Guilty of Libeling Baker

Norman Baker of Muscatine, Iowa, who headed a number of mercantile enterprises, including the ownership of a radio broadcasting station and an alleged cancer cure, was dealt with, editorially, in The Journal of April 12 and April 19, 1930, and in *Hygeia* for May, 1930. As a result of these publications, Baker brought suit for libel against the American Medical Association, asking one-half million dollars in damages. This case came to trial in the federal district court in Davenport, Iowa; the trial opened on February 9 and continued until March 3, covering a period of nearly four weeks. Voluminous testimony was offered by the American Medical Association, both through physicians who went on the stand as experts and by scores of depositions that had been gathered by the Association from various parts of the Middle West; much testimony was also put in by Baker. On March 3, the jury returned a verdict for the American Medical Association.

The case was heard before Federal Judge Gunnar H. Nordbye of Minnesota. In this connection, Norman Baker's weekly paper, the *Midwest Free Press*, prior to the trial expressed the editorial opinion that because the case was going to be heard before a judge who was coming from Minnesota, Baker would "not get all that's coming to him." To quote:

> "We fear he [Norman Baker] will not get all that's coming to him Judge Dewey was to hear the case and at the eleventh hour now announces a judge from Minnesota coming to try the case that may be O. K but WHY WE ASK, is it necessary to go away out of our district to secure a Federal Judge we wonder how Dr. Mayo, who is a power in Minnesota would like it if he were in Mr. Baker's place and an Iowa judge from Muscatine section would hear the case YES WE WONDER Mr. Baker's formulas have accomplished more than Dr. Mayo ever did for cancer, and Baker will have to fight many years yet to educate the ignorant prejudiced and lazy thinking ones who are dominated by organized medicine." [Capitals as in the original. Ed.]

The implications in this statement are fairly obvious.

The jury before whom the case was heard was a group of substantial farmers or retired farmers and merchants. Counsel for the Association were Messrs. Edward M. Burke and Clement L. Harrell of the law firm of Loesch, Scofield, Loesch and Burke of Chicago, with Mr. C. M. Dutcher of the firm of Dutcher, Walker and Ries of Iowa City, who are the attorneys for the Iowa State Medical Society. Norman Baker was represented by two attorneys, Messrs. Charles P. Hanley of Muscatine and J. C. France of Tipton.

Appearing as medical experts for the Association were Dr. Francis Carter Wood of New York, Dr. Joseph Colt Bloodgood of Baltimore, Dr. Burton T. Simpson of Buffalo, Dr. Max Cutler of Chicago, and Dr. Albert C. Broders of Rochester, Minn. Several other physicians also aided the Association, appearing either as witnesses during the trial or by depositions.

BAKER'S ENTERPRISES

Originally, Baker's enterprises seemed to have been wholly or mainly in the commercial field. He sold radio sets, storage batteries, flour, coffee, canned fruit, silverware, brooms, alarm clocks, overcoats, mattresses, automobile tires, typewriters, paints, and many other things. He advertised his wares not only through printed catalogs and through his magazine, *T N T (The Naked Truth)*, but, more important, over his radio station, KTNT of Muscatine. Baker's first excursion into the medical field seems to have been the use of his radio station to advertise an injection treatment for varicose veins, exploited by a Davenport physician.

Baker had two (and, for a short time, three) alleged treatments for cancer that were being given at Muscatine in the building that was known as the "Baker Hospital." They were (1) a treatment for "external" cancer, an arsenic powder exploited by Harry M. Hoxsey, whose methods[1] have been dealt with in these pages, and (2) the injection treatment for "internal" cancers of one Charles O. Ozias of Kansas City—who also has received some publicity through The Journal.[2] When the American Medical Association, through its Bureau of Investigation, first began warning the profession and the public against the Baker cancer-cure business, Baker made the fantastic claim that the American Medical Association had offered him a million dollars for his "cancer cure," in order that it might be withdrawn from the market, so that sufferers of cancer would be compelled to resort to surgery, x-rays and radium! When Baker himself was on the stand during the first day of the trial, he denied that he had ever made such a statement, but his denial was offset by the presentation of a letter from the files of the Bureau of Investigation, signed "N. Baker" and which Baker had to admit he had dictated. In this letter Baker definitely stated that it was a "fact that the Medical Trust offered one million dollars on January 3rd 1930 to suppress this treatment."

Norman Baker was the first witness to be put on the stand by the plaintiff, in order to show that the material published by the American Medical Association had caused him serious financial damage. Baker declared that his monthly receipts from his cancer-cure activities started at $1,380 for October, 1929, climbed to $75,232 for June, 1930, and, following the articles published by the American Medical Association, dwindled until in January, 1932, he took in only $7,008.

BIOGRAPHICAL NOTES ON BAKER

Baker, on cross-examination, admitted that his education went no further than a year and a half of high school work. After leaving school he traveled around the country working in machine shops as a die and tool maker. After two years of this, he went into the vaudeville business, putting on "hypnotism" acts "along psychological lines—mental work." He continued in that field for about eight or ten years, but in 1914 came back to Muscatine, where he started to manufacture calliopes. This work was interrupted for a short time when he went on the road again "putting on an act." In 1920, his factory burned and he then started a mail-order business. His broadcasting station went on the air in November, 1925, at which time he was running the "Tangley Institute," "Tangley Company," "Tangley Correspondence School," and some other things. He had a mail-order "art school," although he admitted that he could not paint a picture for his life. Nevertheless, he advertised to teach "oil painting in ten lessons by mail." Under the name of "Tangley Institute," Baker was broadcasting "to let the world know that varicose veins could be cured without operation." The Tangley Institute went out of existence when the "Baker Hospital" was opened.

From the evidence in the case, it appears that Baker's original intention was to make some financial arrangement with Ozias of Kansas City, whereby the Ozias "injection cure" for "internal" cancer could be used at Muscatine. Such plans, however, never materialized and Ozias testified that he had never sold, loaned or permitted Baker to use the formula. Baker was asked, when on the witness stand, who it was that told him what was in the Ozias mixture; he replied: "I refuse to tell." It was a fact, however, that two persons previously connected with Ozias in the exploitation of the Ozias "cure" were hired by Baker. One of these was a woman, Mary Turner, and the other a chiropractor, Charles Gearing. The Turner woman admitted that she had given thousands of injections of the Ozias "cancer treatment" while in the employ of Ozias; she was employed by Baker to do the same kind of work when she came to Muscatine. Mrs. Turner had no medical training and was not even a registered nurse!

THE FIVE TEST CASES

Baker, on the witness stand, admitted that he broadcast over his radio station that he was going to investigate a cure for cancer (the Ozias "treatment") and that he "wanted five men or women from any part of the United States or Canada who were suffering from cancer to consent to become a test patient for this treatment, that I would pay all of their expenses for them, all doctor bills, nurses' care, medical fee, room and board, and they to pay their own transportation to the hospital [in Kansas City, Mo.] where the treatment would be made." It developed that, as a matter of fact, most of the "test patients" paid their own expenses both in transportation and in fees to Ozias. These "test cases" were dealt with extensively in Baker's *T N T Magazine* and the matter was sent out as a reprint, because, according to Baker, the copies of his magazine containing the material had been sold out. The article was headed in black-faced type, "T N T Magazine Investigation Proves That Cancer Is Curable." The article in question started as follows:

---

[1] The Hoxide Cancer "Cure," J. A. M. A. 86:55 (Jan. 2) 1926. The Hoxide Quackery Again, ibid. 93:400 (Aug. 3) 1929.

[2] The Ozias Hospital Association, J. A. M. A. 79:1869 (Nov. 25) 1922.

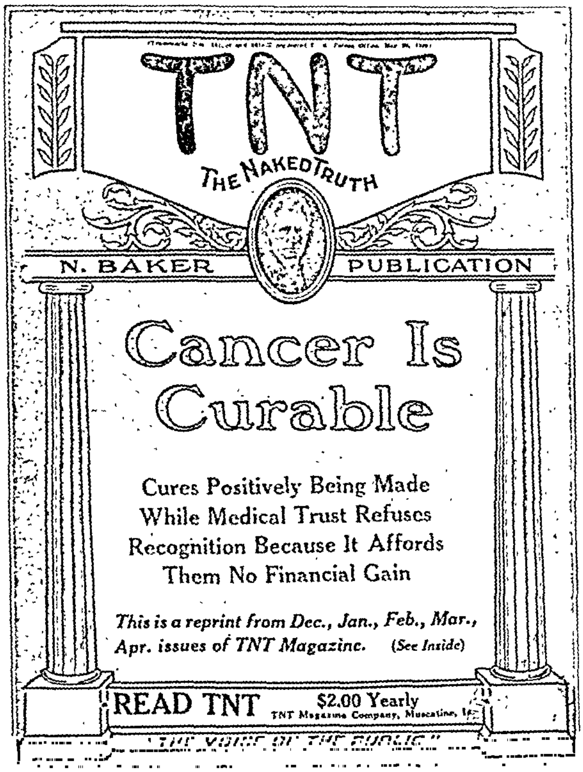
> "Cancer is conquered. The greatest discovery in medical science in years—a positive cure for cancer, that dread disease which has taken toll of millions of lives, caused thousands to commit suicide and driven other thousands to insanity—has been revealed by an investigation conducted by Norman Baker, publisher of T N T magazine and owner of the Norman Baker Enterprises and radio statition KTNT, who was assisted by a physician and member of his staff.
>
> "Seeing is believing. Mr. Baker and his fellow investigators have seen with their own eyes enormous and malignant cancers in advanced stages of growth rapidly yield to a new and painless treatment, soften and disappear. They selected the cancer cases themselves for observation after they had determined beyond any doubt that they were authentic cases of cancer. They have watched these true cases of cancer under treatment and have seen the cancers grow smaller and pass away."

Baker then went on to state that "painstaking observation" of the cases that had been selected for the test had "thoroughly convinced Mr. Baker that cancer has been conquered." The article then goes into detail regarding the five test cases, reproducing photographs of the individuals concerned. Here it may be interpolated that all five of the patients are dead and were dead for some some time before Baker ceased reprinting his article to prove that "Cancer Is Conquered."

Test Case No. 1.—Mrs. T——— was one of the widely advertised "test" cases. Mrs. T——— was taken to Ozias' place in Kansas City by her daughter-in-law, who testified that when they got there, they met Mrs. Turner, who, at that time, was employed by Ozias. Mrs. T——— stayed at the Ozias "clinic" from July, 1929, until September of the same year, and she paid $105. According to Baker's announcement, Mrs. T——— was "suffering from a very bad abdominal cancer" and had been given up by physicians as incurable. Following the Ozias "treatment," according to the Baker report, she began a "rapid recovery" and the "cancerous mass in the abdomen had softened and most of it had passed away." The article added that "only a small amount of cancerous growth" was left and this "no doubt will be eliminated when she resumes the treatment." The facts developed in the trial showed that Mrs. T———, when she returned from Kansas City in September, was practically bedfast, and she died a few weeks later—in November, 1929. This case, heralded by Baker as one of the five "test" cases, was published first in the December issue of *T N T Magazine* and the matter was reprinted and distributed as late as June, 1930—more than half a year after the poor woman had been in her grave!

Test Case No. 2.—Another of the "test" cases was that of Mr. De C———, who had cancer of the throat. Reputable surgeons to whom he went, while not holding out any hope of cure, suggested, as a palliative treatment to prolong his life, the surgical removal of the vocal organs. This he refused and came to Baker. The Baker magazine stated, in describing the case, that "it was believed that three months' treatment would be required to completely cure him" and reported, further, that after treatment Mr. De C——— "went back to work at his trade." The case was reported in detail in a Baker reprint that was sent out in June, 1930—six months after Mr. De C——— was dead and buried! Mrs. De C——— testified that her husband, a laborer, paid $500 for the two months that he was in the Ozias "clinic" at Kansas City. She was asked if it was not a fact that Baker told her, at the time, that he (Baker) would take care of the expense of Mr. De C——— going to Ozias. Mrs. De C——— replied: "Well, he said if he got somebody to send up there, he would pay all of the expenses, but he didn't pay anything. I paid my expenses myself." After his stay at the Ozias "clinic," Mr. De C——— came back to Muscatine, having learned that the Turner woman, previously an employee of Ozias, was now employed by Baker. He continued to take "treatments" in Muscatine, the injections being given by Mrs. Turner. He was there about two and one-half weeks and was charged, according to the testimony, $137.50. Mrs. De C——— testified that Mrs. Turner told her, at the time she went to bring her husband back home, that there was nothing to fear from the cancer "because he is cured, but there is only one thing; his windpipe bothers him and all you will have to do, you go home with him and put some onions on his windpipe. That is all you will have to do."

Test Case No. 3.—This was that of Mr. D———, which was described in Baker's magazine and reprints as that of a patient who had had an exploratory operation by reputable physicians, which disclosed the fact that the case was inoperable. Mr. D——— went to Kansas City to take the Ozias "treatment" in September, 1929, and remained there seven weeks. Mrs. D———, who was called as a witness by the American Medical Association, declared that after Mr. D——— came back from Kansas City he was unable to keep any food down: "he always vomited it up." On his return to Muscatine, the "treatments" were continued until the last part of October or the first part of November, when Gearing and the Turner woman refused to continue them. Mr. D——— died, Dec. 28, 1929. Mrs. D——— asked that a necropsy be done on her husband's body, because Baker had claimed that, in addition to suffering from carcinoma, Mr. D——— was suffering from tuberculosis. The necropsy showed that Mr. D——— had no tuberculosis, but cancer. Baker, in his write-up of this "test" case, said:



TNT

THE NAKED TRUTH

N. BAKER PUBLICATION

Cancer Is Curable

Cures Positively Being Made
While Medical Trust Refuses
Recognition Because It Affords
Them No Financial Gain

This is a reprint from Dec., Jan., Feb., Mar., Apr. issues of TNT Magazine. (See Inside)

READ TNT $2.00 Yearly TNT Magazine Company, Muscatine, Ia.

> "At this writing the cancer which originally covered practically the entire abdomen has been reduced to a lump about the size of a small walnut. It seems certain from his present condition that the treatment will not only cure his cancer but will free him entirely from tuberculosis."

When it was obvious that Mr. D——— would not live much longer, the Baker "institute" refused to give further "treatments," and Mrs. D——— testified that Baker claimed that the reason her husband was not getting well was that he was not taking enough exercise. When Mrs. D——— was asked about this she replied: "How could he exercise when he didn't have any strength to exercise with? One of us had to get on each side of him to make him walk a few feet." Another alibi that Baker attempted to use in this case was that Mr. D——— was smoking too many cigarets. Mrs. D——— declared that her husband had been unable to smoke cigarets since the time he had the exploratory operation and before he ever even went to Ozias or Baker.

Test Case No. 4.—Another of the "test" patients was Mr. J——— of Kansas. Mr. J——— had cancer of the jaw; he had been operated on and given radium irradiations by reputable physicians, who could hold out no hope of permanent cure. Following the operation he went to the Ozias "clinic" as one of the "test" patients. He remained in Kansas City from September, 1929, to March, 1930, and paid out between $700 and $800 in addition to his transportation expenses. In one of Baker's reprints, sent out at late as June, 1930, it was stated regarding Mr. J———:

> "At this writing the patient has recovered sufficiently to begin to worry over the fact that due to the operation he is destined to go through life disfigured. He keenly feels that had he known about the treatment sooner he could have saved both his life and his face from disfigurement. On this account, he harbors considerable resentment towards the doctors who performed the operation."

When this reprint was issued, Mr. J——— had been dead more than a month! He died, May 5, 1930.

Test Case No. 5.—Mrs. N——— of Illinois was still another of the five "test" case patients. Mrs. N——— had cancer of the right breast. Having heard Baker broadcast, she went to Muscatine, where she was accepted as one of the "test" cases to go to Ozias. She stayed at the Ozias "clinic" for about two months, at which time she wrote to her husband, according to the testimony of her son, that if they "didn't come after her, they will bring her home in a box." The son also testified that the mother paid between $250 and $300 in addition to her traveling expenses. The son also testified that when his mother went to Kansas City "the cancer was about the size of a half-dollar," and that when she returned "it was two or three times bigger." The Mrs. N——— "test case" was being reported by Baker as late as June, 1930; she died of cancer, Feb. 25, 1930!

THE CASE OF MR. MCL———

Another case that did not belong to the five "test cases" but which was heralded by Baker as a cure was that of Mr. McL——— of Kamsack, Sask., who had cancer of the esophagus. Mrs. McL——— testified that her husband had consulted several reputable physicians in Canada and the United States before going to Muscatine. They were persuaded to go to the Iowa town after she and her husband heard Baker and his manager, R. A. Bellows, broadcast over KTNT about their "institute." As a result, they sent Baker a telegram and received a reply to the effect that the Baker Institute would treat her husband for $100 a week. Mr. McL——— stayed at the "institute" nine weeks and paid Baker $400 in cash and, in addition, signed two notes, one for $280 and the other for $200, which were later returned.

Mrs. McL——— said that when they first arrived in Muscatine the "Baker Hospital" had not opened, so they went to Baker's store, where they were told that the "cancer doctor" was out but that they could see him later. This "doctor," it later developed, was chiropractor Gearing. Mrs. McL——— worked in the Baker establishment while her husband was there, in order to help reduce the expense to which they were put. She testified that while she was given a job as a nurse at $25 a week, the price Baker was charging her husband was immediately raised from $100 a week to $125 a week! She protested at this and called attention to the fact that other patients were receiving treatment at $50 a week. Not until Mrs. McL——— threatened to give the facts to the newspapers did the Baker concern reduce the rates for her husband to $85 a week.

Mr. McL——— finally got so weak that he had to be taken back to Saskatchewan. Mrs. McL——— further testified that one night after their return and but a short time before her husband died, they happened to turn on the radio and heard Baker, over KTNT, say: "Hello, Kamsack, Canada. Hello, Mr. and Mrs. McL———, how are you?" Baker then went on to describe Mr. McL———'s treatment at the "institute" and told how he had been sent home cured, how he was able to eat solid food, and how Mrs. McL——— had written to Baker, stating that her husband "was coming along fine." The facts were, according to Mrs. McL———, that she never wrote to Baker after returning to Kamsack, and that her husband had *not* been able to eat any solid food since leaving the "institute." Mr. McL——— died, April 12, 1930.

It was brought out in Mrs. McL———'s testimony that at the time she and her husband left the Baker Institute, Mrs. Turner, who with chiropractor Gearing had been giving the injections, gave her a small bottle of the injection fluid, with instructions that should her husband need it, she should get a nurse to administer it, but under no circumstances allow it to get into the hands of a physician. Mrs. McL———, however, turned over the specimen to her family physician, Dr. C. E. Tran, who later gave it to Mr. Edward M. Burke, defense counsel. Mr. Burke deposited half of the liquid with Dr. Paul Nicholas Leech, director of the A. M. A. Chemical Laboratory, and half with Dr. Wilber J. Teeter, dean of pharmacy at the State University of Iowa, with the request that both men analyze the material. Later, both Dr. Leech and Dr. Teeter testified that their analyses of this liquid disclosed that the product was essentially one-third carbolic acid (phenol) in a mixture of glycerin and alcohol, with a trace of oil of peppermint.

THE OPEN-AIR SHOW

One of Baker's advertising stunts was characteristic of a man who had been in the "show business." He broadcast that the Baker Institute would hold an open-air meeting at Muscatine, where it would be demonstrated that both external and internal cancer was curable by the Baker methods. In the June issue of *T N T Magazine*, it was claimed that 32,000 people attended this meeting. In the same issue he purported to describe some of the "wonders" that were shown at that time. One of the more spectacular was thus described:

> "Most amazing and remarkable of all, the entire top portion of the skull of a patient almost in the last stages of cancer was removed and held up for exhibition by the physician before the gasping throng exposing the brains of the entire top of the patient's head."

This was the case of one M——— J———. Large-sized reproductions of photographs were published in *T N T Magazine*, one showing Mr. J——— "with bare skull bone exposed," another showing one of Baker's hired men "just after he had administered treatment and removed skull exposing brain," and a third showing what purported to be a "close-up view of brain of M——— J———" and the alleged "cancerous growth which was eating his life away." Investigation brought out the fact, obvious to any physician, that the man never had cancer but *did* have an osteomyelitis. The condition was treated by Hoxsey at the Baker Institute and, while there, the outer layer of the skull was, as the patient put it, "just pried off." What the gaping crowd saw at the "demonstration" was not the man's brain, as reported by Baker, but the medullary portion of the skull.

THE CASE OF MRS. MCM———

The case of Mrs. McM——— also carried some interesting high-lights. Mrs. McM——— had cancer of the esophagus diagnosed by reputable surgeons as inoperable. After hearing Baker over the radio telling of the cures that were being performed, she and her husband went to Muscatine, where they met chiropractor Gearing and Mrs. Turner. The day before Mrs. McM——— died in the Baker Institute, according to the testimony of her husband, another of the alleged doctors of the "institute" examined her and "said she was all ready to go home, and he told Mrs. Turner her heart was good and her cancer was all gone and she could go home and build up quicker than she could there." Mrs. McM——— died the next day! Mr. McM——— had paid $800 in cash for three months' treatment and had been told that if his wife did not receive any benefit the Baker Institute did not want his money. In spite of the fact that the poor woman died after being in the "institute" only a little more than sixty days, it was necessary for Mr. McM——— to employ an attorney to get a refund.

THE CASE OF MRS. W———

Mrs. W——— went to the Baker concern for cancer of the breast. Her husband testified that she went to Baker because she had a horror of surgery. This point is worth emphasizing for reasons that will appear later. They first saw Bellows, the business manager, who, when he heard she had not had any treatment, operative or otherwise, said "that was fine." Later, they saw Baker, who, according to Mr. W———'s testimony, said: "One thing I am thankful for, folks; this is a virgin case. I am awfully glad *you never let any other doctor tamper with it.*" Baker went on to state, according to the witness, that within a week or ten days, they could tell Mr. W——— whether they could cure his wife or not. They were charged $50 a week and the patient was put in a room containing "either six or seven" other patients. Mr. W——— testified that he saw Hoxsey treat his wife and, later, described how Dr. Statler, who is legally licensed to practice medicine in Iowa, also gave her treatments *under Hoxsey's direction!* The following excerpt from Mr. W———'s testimony on this point is enlightening:

> "*Question.*—Did you see anybody else treating your wife in any manner at the Baker Institute?
>
> "*Answer.*—Dr. Statler.
>
> "*Q.*—What did you see him do?
>
> "*A.*—Well, they had taken the Mrs. into his office one afternoon and laid her on a kind of a table that they had there and Hoxsey sat down on one side and Statler stood up right at about her shoulders and I stood back kind of between them and watched the performance. Hoxsey directed Statler as to what to do, where to make the incisions in my wife's breast.
>
> "*Q.*—Did Statler do it?
>
> "*A.*—Yes sir.
>
> "*Q.*—What else happened there on that day, if anything?
>
> "*A.*—As soon as Statler got through making the incisions, that is, it went so far, and I looked at him and I said, 'That is enough; stop it right there.' And at that Hoxsey and two of the nurses that were in the room left the room immediately. Statler and two more—I believe there was two—was still in there and they helped me take the Missus off of the table and put her in the wheel chair to take her back to her room.

And this, it is to be remembered, was the treatment given this poor woman who dreaded the knife—and it was given without any anesthetic! Mrs. W——— died in the Baker Institute a few days later.

SOME MORE CASES

There was the case of DeB———, a young fellow with a sarcoma of the leg. Testimony showed that he went to the Baker Institute, where he was told they could cure him in seven weeks and that it would cost him $75 a week. He stayed at the "institute" fifteen weeks and paid over $700. At the end of that time the young man's mother was told that they could do nothing further for the boy. She went to Muscatine and took him to his home in Rock Island, and the next day he was hurried to a reputable hospital, where an amputation was performed in the hope of prolonging his life. He lived for about six months and died, Sept. 2, 1930.

Mrs. H——— of Missouri had cancer of the breast. She was operated on by a reputable surgeon, who, according to the testimony of her husband, made it perfectly clear to them both that he could not be at all certain that it would not recur. Shortly after the operation, Mrs. H——— went to the Baker Institute at Muscatine, having heard Baker broadcast his "cure" over his radio station, KTNT. She went to the Baker Institute a few days before Jan. 1, 1930, and stayed there until the middle of February, paying about $340. At this time, she was discharged as "cured." She died of cancer, May 21, 1930!

Mrs. G———, who had an extensive carcinoma involving both breasts and both right and left axillary glands, went to the Baker Institute, Jan. 1, 1930. Her reason for going was expressed by the husband in his testimony, thus: "Mr. Baker talked over the radio and said he could cure cancer, no matter where it was located." Mrs. G——— was there, from Jan. 1, 1930, to March 12, 1930. After her return home, Mrs. G———'s condition became progressively worse; she died, July 23, 1930.

Mr. S———, a shoe repairer, had cancer of the pancreas and his family was told that, while some temporary relief could be obtained by an operation, he could not be cured. An operation was performed and Mr. S——— went back to work on the first of November, 1929, and worked until the latter part of March, 1930, at which time he went to the Baker Institute, having heard Baker over the radio. S——— then asked Hoxsey, according to the testimony of his widow, "Well, can you help me?" and Hoxsey replied: "No, we can cure you." He died, July 21, 1930.

Many other cases similar to those just given were introduced by the American Medical Association, but space does not permit even the abstracting of them. Before closing its case, the American Medical Association put in evidence between twenty-five and thirty death certificates of patients who died at the Baker Institute. The Association also submitted seventeen death certificates of Hoxsey victims.

BAKER'S "EXPERTS"

When the time came for Norman Baker to submit testimony to rebut that which had been put in by the American Medical Association, he called to the stand certain alleged experts. The first of these was E. M. Perdue, M.D., of Kansas City, Mo. Perdue qualified as an "expert" on cancer by stating that he had done special research at Johnson's[3] Laboratory for Cancer Research at Kansas City, Mo. According to Perdue, the cancer cell differs from the normal cell in that it contains more water, and the way to kill cancer is to remove the water from the cancer tissue! This is done, said Perdue, by applying escharotics or by injecting "certain chemicals which substitute that water and take it out, and the cancer dies."

Perdue testified that he had never done any surgical work for cancer nor had he ever used radium or x-ray, and that he would use none of these methods of treating cancer. He said that he had used escharotics in the treatment of cancer and he submitted as an efficient formula, equal parts of powdered zinc chloride, powdered gum acacia, powdered sanguinaria, powdered galingal and powdered charcoal. According to Perdue, a product of this sort "deaquafies" the cancer, "taking the water out by substituting another chemical for it." Furthermore, according to Perdue's testimony, when escharotics are applied, they do not destroy normal tissue, because the cancerous tissue is selective. Perdue declared that the development of cancer was due to an increased alkalinity in the tissues of the person suffering from this disease.

On cross-examination it was brought out that Perdue not only approves of the Koch treatment for cancer, but of the Abrams "electronic" theory; further, that he is using, at the present time, what he described as the "Ellis machine," which is apparently one of the many imitations or modifications of the Abrams device. George Starr White[4] is a personal friend of his, said Perdue, and has taught him "lots of things in diagnosis." Perdue testified that he studied law at the same time that he studied medicine; that he began the study of medicine at the Kansas City Hahnemann Medical College and that he taught histology, anatomy and dissection at the same time. "I was a good anatomist," he admitted, and when asked where he learned his anatomy, he said that it was part of his course in the Kansas Normal College. He claimed, also, to have gone to the Eclectic Medical University of Kansas City. It was brought out that although Perdue has for years been practicing in the State of Missouri, he holds no license from the state board of that state; he claims that he has a right to practice because he had been in practice twenty years prior to the time that the law went into effect. Perdue also claimed to be a civil engineer and a chemist; to hold the degree of M.D. from two schools—one homeopathic and one eclectic; to have the degrees of Doctor of Public Health from the Eclectic Medical University of Kansas City. He also took "courses" in osteopathy and chiropractic in Kansas City schools now out of existence. He claimed to be an authority on mixing concrete and declared, under oath, that he had "superintended millions of dollars' worth of public work," having laid miles of asphalt paving. He did this civil engineering in the "summertime, between the school sessions."

Another Baker "expert" was J. W. Seip, M.D., of Erie, Pa. Dr. Seip is seventy-two years old, a graduate of Jefferson Medical College, 1883, and licensed to practice in Pennsylvania. Dr. Seip admitted that his practice, up until the time of the world war, had been largely general, but "since then, it has been more psychologic and chronic diseases." He said that he "had never done much of any research work on cancer" but, nevertheless, it was his expert opinion that cancer resulted from the "present devitalized condition of our diet" by which "we rob our blood of its known necessary twelve tissue salts." Dr. Seip further was of the opinion that persons suffering from cancer were nearly all "shallow breathers" and that they were the people who were "living on white bread depriving themselves of the salts of our tissues, which are mainly in bran." He declared: "One reason why cancer is so prevalent today is because people eat white bread, and the whiter the bread, the sooner you are dead." The doctor said that in his own treatment of cancer his "principal reliance is upon the Koch antitoxin." The Bureau of Investigation has in its files advertisements from Erie (Pa.) newspapers of eight years ago, reading as follows:

---

[3] The Johnson cancer concern is dealt with in the pamphlet "Cancer Cures and Treatments" issued by the Bureau of Investigation of the American Medical Association.

[4] See article: "George Starr White—Quack," The Journal A. M. A., April 13, 1929.

ERIE'S ONLY
Permanent Office Specialist
For Chronic Diseases

Cures high blood pressure, rheumatism, neuralgia, varicose veins and ulcers, scars and strictures, hemorrhoids, weakness, debility, nervousness, etc., without pain.

Hours: 1 to 4 and 7 to 9 P. M.
DR. SEIP
1031-33 State Street.

A third "expert" called as a witness by Norman Baker was Bruce Miller.[5] He testified that he was graduated in 1886 by the College of Physicians and Surgeons, Chicago; that he was "out of practice for quite a number of years" but that in 1926, he went to Taylorville, Ill., where he was connected with Harry Hoxsey and his "Hoxside Institute." He practiced for a short period right after graduation and then worked in a factory and as a paper-hanger from 1891 to 1898; that he then "built up quite a large orchestra of ladies, dummies, in connection with a pipe organ" and went to Europe, where he took his "dummy" troupe and exhibited his "automatic orchestra." He was in Europe from 1899 to 1906, when he returned to the United States and entered the real-estate business, in which he continued until about 1918. Dr. Miller testified that the only treatments he administers for cancer are escharotics and that he does not attempt to treat any cases of "internal cancer," although he admitted that cases of that kind were accepted and the patients were given narcotics to make them comfortable.

The fourth "expert" called by Norman Baker was Harry Hoxsey himself. Hoxsey testified that he was thirty years old and that his education had not extended even through the eighth grade; he then worked as a coal miner and, in 1921, he started in the cancer-cure business at Taylorville, Ill. Hoxsey testified that he went to Muscatine with Norman Baker in March, 1930, and stayed at the Baker Institute until September 4, 1930, on a percentage contract basis. He admitted that he treated many patients and even used the hypodermic needle and gave some injections. It was brought out on cross-examination what had been generally known through the newspapers—that Hoxsey and Baker had a disagreement. Hoxsey's explanation of leaving Baker was:

> "I told Mr. Baker I refused to be a party any longer to bringing people there to take any other treatment only mine because he had shown no results with any other treatment on external cases and I would truthfully say not one, for I haven't seen one single case of external cancer cured there where the powder was not used."

He complained that Mr. Bellows, instead of sending the cases that come in for Hoxsey's powder treatment, would "consign them to the needle department where the intramuscular treatment was used." Hoxsey declared that he had sworn: "I have not seen one case of internal cancer leave that institution Baker Institute as cured that did not take my cancer treatment."

Following Norman Baker's "experts," there were put in evidence a number of alleged cases of cancer that were said to have been cured at the Baker Institute. Most of these were of a superficial type and those of the so-called internal type were not satisfactorily diagnosed as cancer. Baker put on the stand some of the individuals who were alleged to have been cured and, at the same time, presented photographs of the "before-and-after" type as confirmatory evidence. Incidentally, during the closing days of the trial, the United States Marshal took a loaded .38 automatic pistol from Norman Baker. Baker's excuse was that he had a permit to carry one, but he was informed that his permit did not extend to the federal courts.

THE CLOSING ARGUMENTS

In the final arguments, Mr. Dutcher, for the American Medical Association, made no attempt to soften the charges that had been made in The Journal and *Hygeia* regarding Baker. "We called Baker a quack and we are not here to apologize for it," Mr. Dutcher declared. He brought out, further, that the State of Iowa had enjoined Baker from practicing medicine without a license and that the Federal Radio Commission had revoked Baker's broadcasting license, because it found that his operation of the station was inimical to the public interests. He reviewed the history of the five "test" patients that Baker had sent to Ozias at Kansas City, Mo., and emphasized the fact that they were all dead at the time that Baker was declaring, either directly or by implication, that they had been cured. Mr. Dutcher maintained that there was not a single case in the record of the trial in which the Baker Institute could even claim to have cured a case of cancer with its hypodermic injections. Counsel also referred to the fact that Hoxsey and Gearing, neither of whom had any medical training, were known as "Doctors" at the Baker Institute.

Mr. Dutcher also asked why Gearing and Dr. Ozias and numerous other doctors who had been connected with Baker, had not been called by Baker to testify in the case. As Mr. Dutcher stated, not a single M.D. who was associated with the "institute" before the date of publication of the alleged libelous articles had been called to testify, except Dr. Statler, who still had a job there. He dwelt on the evidence in the records showing that Statler once cut a woman's breast under the direction of Hoxsey and that in another case, Hoxsey himself cut the breast and the patient died five days later. Mr. Dutcher also dwelt on the case of the young Iowa farmer, who, suffering from what he thought might be cancer, went to the Baker Institute, where Hoxsey started to "treat" him. Not being satisfied that the Baker Institute knew much about his case, the young man went to the State University of Iowa's Dermatologic Clinic, where they found he was suffering from "barber's itch"! This case, as some of our readers may remember, was the subject of a brief article in this department of The Journal for July 26, 1930.

Baker's attorneys, in their closing speech to the jury declared that the American Medical Association was malicious in attacking Baker and that it had no right to attempt to interfere with Baker's business or injure his reputation.

The case went to the jury as the court closed on the evening of March 2; the jury was out for a few hours that evening before adjourning for the night. They returned to the jury room at nine o'clock the next morning, and at 10:50, a ballot was taken and the vote was unanimous for the American Medical Association. Their brief formal report to Judge Nordbye was: "We, the jury, find for the defendant."

Correspondence

NUTRITIONAL ANEMIA

To the Editor:—In The Journal, February 20, page 660, appeared a communication by Prof. E. B. Hart of the Wisconsin Experiment Station relating to the work of Beard and Myers (*J. Biol. Chem.* **94:**71-146 [Nov.] 1931) on the nutritional anemia of the rat. Since this article contains some statements that are misleading and incorrect, I feel it my duty to give the facts in order that erroneous opinions of our work may be corrected.

In the first paragraph it is stated that the work of Beard and Myers has added to the confusion [of nutritional anemia of the rat]. But that confusion will disappear, I am sure, if one turns to page 74 of the November, 1931, issue of the *Journal of Biological Chemistry*. Under the caption "Milk Used," one will read that the milk that they used was "poured through about five feet of copper pipe into a large nickel cooler" and that this milk contained 0.44 mg. Cu per liter." Let us now examine this statement and see whether it has any bearing on the results that we have already published on the question of the nutritional anemia of the rat.

The reader gets the impression from this statement that our positive results were due to the copper contamination of our milk. That the Wisconsin investigators should hold this view is evident from their publications in this field. Our milk was poured through 5 feet of copper pipe which had a diameter of about 5 inches. This pipe extended from the top to the bottom of the cooler. The time that any given quantity of the milk would be in contact with the metal was thus only a few seconds. Furthermore, milk must be heated to a fairly high temperature before it will take up any metal from a container. Thus it was impossible for our milk to take up any copper from this pipe. Identical results were obtained with milk that never came in contact with any metal. Our milk contained 0.44 mg. of copper per liter. We obtained recovery with pure iron. Hart's milk contained 0.32 mg. of copper per liter and no recovery with pure iron was observed. The difference in the copper content of these two milks was 0.12 mg. per liter, or 0.006 mg. per 50 cc. of milk, which would be consumed daily by a young rat. We have shown that this amount of copper, even if it were all absorbed, cannot have any supplementing effect with iron. In from 35 to 75 cc. of milk daily the Wisconsin rats would be receiving from 0.01 to 0.02 mg. of copper, yet no recovery was obtained with this milk when pure iron was added. It required 0.0025 mg. of copper to show a supplementing effect with iron. The amount of copper *in the milk* and that *in the tissues* of the rat are very different things from the metabolic point of view. We have also shown that there is a *minimum daily dose* of copper that is effective with iron and that doses below this will have absolutely no effect. If it was the copper content of the milk that was giving our effect, why did we get such an accelerated effect when 0.025 mg. or copper was added to the milk-iron diets? This point was fully discussed on pages 99 and 100 of the article by Beard and Myers, where evidence with thirty-three anemic rats was given. This evidence showed that our milk did not contain 0.025 mg. of copper daily (our lowest effective dose).

---

[5] Bruce Miller is discussed in the article, "The Hoxide Cancer Cure," already referred to.

Reference was also made to the fact that Keil and Nelson (*J. Biol. Chem.* **93**:52 [Sept.] 1931) used milk containing 0.44 mg. of copper per liter, but on reference to this article on page 93 it is seen that their milk contained from 0.35 to 0.44 mg. of copper per liter. Thus it is just as logical to accept the first figure as the last here. On this milk Keil and Nelson obtained recovery with pure iron, while the Wisconsin group could obtain no recovery with iron when their milk contained 0.32 mg. of copper per liter. When both groups of investigators used milk containing about 0.23 mg. of copper per liter there was no effect when iron was added. One-tenth mg. of copper per liter is equivalent to 0.005 mg. for each 50 cc. of daily milk intake, an amount obviously too small to exert any effect. Thus it is evident that the copper content of milk does not have any bearing on our experimental results.

Reference was made to our work with rats 196-256, in which our milk never came in contact with any metal whatever. We omitted the copper determination of this milk since it gave identical results with our other milk. It was also stated that "their published records show that it was never used with Fe as the only supplement, but only with Fe and Zn." On page 78 of our paper, this statement will be found: "95 anemic young rats fed daily on 0.5 mg. Fe . . . These rats were used as litter mate controls for the experimental animals given in our Paper II" (which contained data for above rats). Suffice it to say that eighteen of these animals were fed on iron alone, with hemoglobin recovery in six weeks, while the rest of them received other supplements with iron, with hemoglobin recovery in three weeks. Results for duplicate groups of rats fed on the same supplements will be found in the tables on pages 95-97.

Elvehjem and Hart (*J. Biol. Chem.* **95**:369, 1932) still infer that our iron solutions contain copper as an impurity. Since we used the hydrogen sulphide filtrate of iron after filtering off the sulphides and removing the gas, with fully 60 per cent of our animals with exactly the same results as with our original iron solutions, it is clearly seen that there is no ground for this continued criticism of our work. If copper is specific in nutritional anemia, how can one explain the positive results of several investigators with pure iron alone? No one will deny the catalytic effect of copper with iron, but there are both experimental and clinical investigators who do not agree that copper is specific in anemic states. Furthermore, Foster (*J. Nutrition* **4**:517 [Nov.] 1931) has shown that irradiation with a quartz mercury arc has a slight but definite effect in increasing the hemoglobin content, number, size and saturation of the red cells in nutritional anemia of the rat. I have, in a preliminary study, confirmed this effect on the recovery in cells.

All the points of technic, and many others, mentioned in the last paragraph were very carefully studied by us in Cleveland and none of them had any effect on the outcome of the experiments.

H. H. BEARD, PH.D., New Orleans.

DIPHYLLOBOTHRIUM LATUM

To the Editor:—In the article on Diphyllobothrium latum (THE JOURNAL, January 23, p. 312) the author states that no cases have previously been reported in the literature from New York.

I reported a case of Diphyllobothrium latum, or Bothriocephalus latus, infestation (the terms are identical) in 1926 from New York City, which appeared in the *Medical Journal and Record* (**124**:536 [Nov. 3] 1926). This paper was further abstracted in the Current Medical Literature department of THE JOURNAL (Jan. 8, 1927, p. 127).

My paper reviewed the literature thoroughly and discussed the theories as to the cause of the anemia arising in this condition. As at that time there were no data on blood changes available, rather elaborate blood studies were undertaken which, although negative, it was hoped would serve as a point of departure for future investigations.

THEODORE ROSENTHAL, M.D., New York.

Queries and Minor Notes

ANONYMOUS COMMUNICATIONS and queries on postal cards will not be noticed. Every letter must contain the writer's name and address, but these will be omitted, on request.

PHYSIOLOGIC STERILITY AND CONCEPTIVE CAPACITY

To the Editor:—What is definitely known as to periods of physiologic sterility and conceptive capacity in women? I have read conflicting statements.

[illegible], M.D., [illegible], Texas.

ANSWER.—It has long been maintained that there exists in women a definite period during each month when conception may take place and other intervals when impregnation is impossible. Most of the individuals who are of this opinion are physiologists and anatomists, whereas those who maintain that women may conceive at any time during the [illegible] are essentially clinicians. The one who has done [illegible] the last few years to attempt to prove that there is a physiologic period of sterility is Knaus. By means of [illegible] elaborate experiments he has come to the conclusion that in women with a twenty-eight day cycle there are definite periods of sterility each month. There are [illegible] women who have a four week cycle. One group shows a tendency to a slight diminution in the interval and [illegible] twenty-six to twenty-eight days. These women, according to Knaus, can conceive only from the [illegible] the cycle. The second group has a tendency to a [illegible] menstrual interval, which [illegible] thirty days. These women [illegible] only from the [illegible] The relatively few women [illegible] six and thirty days [illegible] seventeenth day [illegible] intermenstrual interval [illegible] suggests that the ideal time of [illegible] abstinence during the interval [illegible] has devised an intricate [illegible] means of which any woman with a twenty-six to thirty day interval may determine the exact days each month when conception can take place. Knaus's chief reason for his belief in physiologic periods of fertility in women are that: 1. Since spermatozoa lose their power of fertilization after forty-eight hours and since ovulation does not occur until about the fourteenth day, coitus during the first ten days of the cycle cannot result in conception. 2. If we agree with Grosser that a minimum of ten days is required for the wandering period of an ovum, it follows that, in women with a twenty-eight day cycle, ovulation and conception must occur together approximately on the fourteenth to the sixteenth day of the cycle so that implantation may occur and prevent the onset of menstruation.

Many individuals take issue with these statements. First of all, some women ovulate as early as the ninth day of the cycle and hence are susceptible of fertilization on that day or even earlier. Secondly, there appear to be authentic records of a single coitus during the intervals that are supposedly sterile, nevertheless with the occurrence of conception. Of course, many women have good reasons for not telling the truth about these matters and sometimes their memory is at fault; hence not all of these cases are reliable. Theoretically a woman is capable of conceiving only for a short period of time after ovulation; that is, some time between the tenth and the nineteenth day of the menstrual cycle. This is due to the fact that an ovum is susceptible of fertilization for only a few hours and the spermatozoon's capability is not much longer. (The fact that a spermatozoon is motile does not necessarily imply that it is capable of fertilization.) It seems that some women, at least, may conceive at any time in the menstrual cycle even during active menstruation. Far more data are necessary before this question can be settled definitely in human beings. Perhaps the intensive studies being made on monkeys will shed a good deal of light on it. Thus far it seems that monkeys do have a distinct physiologic period of sterility.

OTOSCLEROSIS

To the Editor:—A man, in 1917 at the age of 21, had a bilateral 20/20 hearing. After that time he was more or less continuously exposed to cold and damp weather, whereas before he had led an indoor life. In 1918 a bilateral tinnitus developed, on the left side more than the right, and in 1919 he became noticeably hard of hearing, particularly in the left ear. The condition was diagnosed as bilateral chronic catarrhal deafness. He became progressively more hard of hearing with increased tinnitus, so that in 1928 and 1931 a definite diagnosis of otosclerosis was made. While the etiology of otosclerosis is not clear, would it not be reasonable to assume, first, that the cold and damp weather was an aggravating factor in producing the otosclerosis; second, that the tinnitus was the presenting symptom of otosclerosis; third that, since it is known to be difficult to differentiate between chronic catarrhal deafness and incipient otosclerosis, the definite otosclerotic condition which appeared at the later date was in fact the underlying condition present but unrecognized during the entire period? Please omit name. M.D., New York.

Answer.—The exact etiology of otosclerosis or, as it should more properly be named, spongification, is not definitely known. In the typical cases there is a partial or complete ankylosis of the foot plate of the stapes in the oval window and this carries with it loss of hearing for low tones, prolonged bone conduction and a negative Rinne reaction; namely, bone conduction longer than air. When spongification appears in the bony capsule of the labyrinth at points elsewhere than at the oval window, degenerative changes occur, with signs and symptoms of impairment of the inner ear or perception apparatus. In these cases there is loss of hearing for the high tones, diminished bone conduction and a positive Rinne reaction with air longer than bone, but both factors shorter than the normal. However, in cases in which there are changes both in the oval window and in other portions of the labyrinth there is a combination of signs and symptoms that makes the exact diagnosis difficult. In a typical otosclerosis there is usually an hereditary factor and the disease begins to manifest itself quite early in life. It is doubtful whether, in the case cited, otosclerosis was really present because the patient apparently had normal hearing at the age of 21, and then following exposure there developed what apparently was a bilateral tubal involvement, which became progressively worse. If a true otosclerosis had been present, no doubt symptoms would have presented themselves at the age of puberty and become progressively worse. Otosclerosis itself is not supposed to be caused by any acute or chronic infection of the middle ear, but infections or disorders combined with an otosclerosis naturally make the hearing still worse. Tinnitus is one of the most striking symptoms of otosclerosis, but it may be due to many other conditions. Unless the typical tuning fork and other signs are present together with a history showing factors such as heredity, sex and pregnancies (which of course would not apply in the present case), the diagnosis is difficult to make. In this case it seems unlikely that an otosclerosis was present, for it could hardly have existed such a long time before making itself manifest.

SEQUELAE OF IRRADIATION OF THE THYROID

To the Editor:—A woman, aged 50, during the period from 1915 to 1920 received sixty roentgen treatments for the purpose of decreasing a thyroid activity. Soon after the last treatment was taken, she noticed the formation of superficial scar tissue about 4 inches in diameter and lying immediately over the anterior lower thyroid and upper sternal region. This scarred area is infiltrated with numerous small capillaries, giving the area a reddened appearance. Can you suggest any kind of treatment that may aid in the absorption of this scarred tissue and the disappearance of the superficial capillaries? Please omit name.

M.D., Michigan.

Answer.—Scar formation with telangiectatic dilatation of skin capillaries is a *not infrequent result of overdosage of radiation* over the thyroid for the control of hyperthyroidism. It may be an early or indeed a late development, not appearing for several years following irradiation of the area. There is no known effective treatment for such untoward results save skin grafting, which, under the circumstances and in this location, constitutes a formidable procedure and would be indicated only when the scar in itself produces disability. While disfigurement, as in this case, is an unfortunate result, it probably would only be aggravated by radical measures. Incidentally, the amount of x-ray exposure used in such procedures should be exactly measured. Such factors as the quality of the x-rays employed, penetration, screening, length of exposure and extent of skin surface exposed to the rays should be accurately estimated and controlled. The statement that sixty roentgen treatments were employed implies lack of understanding of the principles involved. Under the circumstances a frank explanation of these facts to the patient and the statement that during the period from 1915 to 1920 the importance of these matters was not as well understood as it is today may clarify the situation. It is likely that little or nothing could be done at the present time to relieve the patient from this unfortunate result.

EDEMA IN ONE LEG

To the Editor:—A woman, aged 56, recovering from bronchopneumonia, has old diabetes mellitus and nephritis. The urinary sugar is 1.8 per cent.; albumin, 2.1 Gm. per thousand cubic centimeters; casts, 1 granular; specific gravity, 1.024. I cannot find a suitable diet for this condition. Also there is an edema of only one leg, the left. She shows no obstruction, pain or discoloration of the limb and feels well otherwise. Her heart is good. I cannot seem to find a reason for the edema in one leg.

Samuel S. Schept, M.D., Union City, N. J.

Answer.—It is not easy to find a suitable diet for the combination which this patient shows. Usually some sort of compromise has to be adopted. A comparatively low proportion of protein, say 50 Gm., and a relatively high proportion of fat, seem to be the best combination. Usually edema of one leg is due to local disturbance of the blood vessels; after a bronchopneumonia the patient may have had a comparatively mild thrombophlebitis of the veins of the left leg with secondary edema and without any great amount of pain or discoloration. It is difficult to figure a renal edema being unilateral.

GLYCOSURIA IN PERITONITIS

To the Editor:—A man, aged 37, came into the hospital with a perforated duodenal ulcer of fourteen hours' duration, and there was a large *amount of gastric contents in the peritoneal cavity, probably 2 quarts.* The urine showed a strong reduction of Fehling's solution and in spite of about 350 units of insulin over a period of thirty-six hours the urine reduced the Fehling's solution just as strongly as before the insulin was given. Four hours before death he went into a coma, suggesting diabetes, and his death was distinctly due to respiratory failure. There was in the past history nothing to indicate a previous diabetes, he had passed an examination for life insurance less than a year before and he was employed by one of the large oil companies requiring yearly examination; he had no polyuria, no nocturia, and no excessive thirst. He was about 5 feet 11 inches (180 cm.) tall and weighed 150 pounds (68 Kg.). Facilities for blood sugar determination are not available here. In view of these facts the question arises as to whether a large amount of irritating material in the peritoneal cavity will so irritate the pancreas as to inhibit its secretion and prevent the proper metabolism of sugar to produce this condition. Please omit name. M.D., Texas.

Answer.—According to present knowledge of the physiologic causes of sugar in the urine, peritonitis per se does not produce glycosuria. Theoretically the type of chemical irritation produced by a perforated ulcer, duodenal in particular, may in twelve or fourteen hours cause such damage to the pancreas that it is no longer able to secrete insulin. Experimental and clinical observation, however, shows that acute pancreatitis is rarely associated with the presence of sugar in the urine. In this case two explanations are possible:

1. The patient had a latent diabetes, not discovered in the course of previous examinations. The perforation and subsequent peritonitis produced a toxicity that resulted in a lowering of the renal threshold, throwing out sugar in the urine: that is, a renal glycosuria.

2. The most probable explanation is that this was a case of suprarenal glycosuria with the following mechanism: The great amount of fluid spilled into the peritoneal cavity produced a direct or reflex stimulation of the sympathetic nervous system, which in turn affected the suprarenal glands and an abnormal amount of epinephrine was thrown into circulation, resulting in a mobilization of sugar from the glycogen of the liver and muscles. The blood sugar in this type of glycosuria becomes high and it is also refractory to insulin therapy.

TREATMENT OF EMPYEMA

To the Editor:—In THE JOURNAL, Dec. 26, 1931, Dr. Hedblom mentions the use of "acid pepsin solution" as recommended by Hermannsdorfer for the purpose of destroying necrotic materials in an empyema. A patient, aged 58, in whom an empyema (nontuberculous) developed one and a half years ago following a thoracotomy for a fibroma of the mediastinum, which was successfully removed, is still being drained. Surgical solution of chlorinated soda of 0.5 to 1.5 per cent has been used several times daily since its development by irrigation through a catheter. The cavity is of about 150 cc. capacity and permits the entrance of a catheter 9 inches long. On several occasions, small pieces of bone have been removed through the catheter by aspiration. It is safe to assume that other pieces of bone too large to be aspirated through a catheter still remain in the cavity. The patient is otherwise in good general health. Is the use of acid pepsin solution indicated? If so, please give in detail the technic for preparing and using this solution. Can the chlorine solution be safely used in conjunction with it or would physiologic solution of sodium chloride be indicated? Please omit name. M.D., Illinois.

ANSWER.—If an acute empyema is treated by aspiration of the pus and irrigation of the cavity through a small tube, introduced through a stab wound, and fibrin interferes by plugging the tube, the fibrin may be dissolved by the introduction of acid pepsin.

A chronic empyema cavity that contains sequestered bone should be explored and all foreign material removed. Then a thoracoplasty may be done, or the thoracotomy opening may be sutured and irrigation continued. Eventually, it is usually necessary to mobilize the chest wall sufficiently to obliterate a residual cavity. Any empyema cavity treated by irrigation should be kept empty of pus all the time, which means thorough irrigation until the fluid comes back clear every two hours during the day and twice during the night.

PSYCHIC DISTURBANCE OR PHYSICAL CHANGE?

To the Editor:—Will you kindly advise me concerning the following case, as to a possible cause, prognosis, recurrence and treatment: A woman, aged 53, a trained nurse and medical missionary, suffered complete loss of memory from 7 a. m. to 1:30 p. m. The patient has been married for twenty years and has two sons, the younger 15 years of age. She lives at an altitude of 7,500 feet, 2 degrees south of the equator, works mainly with the Africans, has been here a little more than four years without a return to America, is tired much of the time and is nervous and irritable. At the time of the lapse of memory, her husband was away for just a few days on mission business. He is often away at times thus and there was no particular cause for worry. She wanted to know where her husband was and why he was away, though she knew all about it when he left; she kept saying the same thing over and over again, worried about herself and thought she was insane. A local physician told me that he has many such cases, especially in nervous women who may be physically normal otherwise. M.D., East Africa.

ANSWER.—The facts given are not sufficient to justify a conclusion as to the nature and cause of the condition. The concomitant facts of fatigue, nervousness and irritability would arouse a suspicion of a functional or psychogenic disturbance, but it would be essential to exclude organic factors such as cerebral arteriosclerosis at this age. In view of the mode of life that is described, it is possible that the relative isolation and monotony, with the absence of familiar contacts and relaxations, may be important, particularly during the period of the climacteric; it is also possible that the altitude may play a part in one not accustomed to it. In some respects, except for the acute episode described, there is some suggestion of the attacks of depression that are not uncommon in the period of involution. Without more knowledge of the facts it is perhaps unwise to make suggestions concerning treatment, but the most obvious suggestion is that a period of vacation in more usual surroundings would be advisable.

CARMINE AS A FACE ROUGE

To the Editor:—Can you give me information about the toxicity and absorbability of carmine when used as a face rouge? Is it injurious to the skin? Please omit name. M.D., Connecticut.

ANSWER.—Carmine is made from cochineal, derived from the dried bodies of insects that live on certain cactus plants. Cochineal has no proved medicinal or toxic properties and is used for coloring medicinal tinctures and many food products. The only possible harm that could come from carmine would be due to sensitization of the skin to it, which is unlikely but not impossible. The patch test might be tried on a patient's arm. Some carmine is dissolved in a little water, a small piece of cotton is soaked in it, and the cotton is fastened on the arm with adhesive plaster. A control test is made with cotton soaked in plain water or physiologic solution of sodium chloride. If, after forty-eight hours or less, there is found a patch of dermatitis under the carmine cotton and not under the control or under the adhesive plaster, the patient is sensitized to carmine. A negative result does not disprove sensitization, for it may be localized to small parts of the skin. The test should be repeated on the patient's cheek. If negative here, the irritation was not due to carmine.

INTERPRETATION OF DIAGNOSTIC TESTS FOR SYPHILIS

To the Editor:—I should like to know the exact interpretation of a negative Wassermann, positive Kahn and 4 plus Kolmer reaction as a blood reading in a Negress, aged 28. Is the usual antisyphilitic treatment indicated in this type of patient on the strength of the blood examination? Please omit name. M.D., Arizona.

ANSWER.—A repeatedly positive Kahn and 4 plus Kolmer reaction must be interpreted as indicating the presence of syphilitic infection. It is assumed that yaws and leprosy are excluded from the diagnosis. Whether or not the usual antisyphilitic treatment is indicated is a purely clinical problem and cannot be answered without considering the various manifestations presented by the patient, especially as to the nature of the lesions and the existence of pathologic conditions that might render treatment inadvisable. Only a careful clinical study of a patient can enable one to decide this matter.

PREMATURE MENOPAUSE FOLLOWING IRRADIATION

To the Editor:—A woman, aged 26, because of intractable dysmenorrhea and metrorrhagia submitted to high voltage roentgen exposure of the ovaries on the advice of a gynecologist. Treatment was instituted at the beginning of April, 1931, and finished at the end of the same month. The menses promptly ceased. In July she began to manifest menopausal changes (hot flashes, irritability, nervousness and loss of libido). Is there any hope that this change is temporary and that the patient will menstruate once more? Is it possible for her to ovulate at this time without menstruating? Will the parenteral or oral administration of female sex hormone, theelin or amniotin relieve the distressing vasomotor instability? Can you offer any advice or therapy for this unfortunate woman? Please do not mention name. M.D., New York.

ANSWER.—Small doses of x-rays or radium are approved by some leading gynecologists, but the majority are still reluctant to use this form of therapy in young women. The patient apparently received more roentgen therapy than was intended; despite this, there is a fair prospect that the ovaries will again become active. If there is a return to normal activity it will probably occur within a year or a year and a half. The remedies mentioned are worthy of a trial, although the results thus far obtained have been only fairly satisfactory.

PSEUDOREACTION IN SCHICK TEST

To the Editor:—I have two patients, girls about 8 years of age, who were Schick positive six months after toxin-antitoxin (Parke, Davis & Co., prepared with goat serum). The reaction was marked, probably 3 inches in diameter, red, swollen and indurated. They received another course of toxin-antitoxin. Now, a year later, their reaction to the Schick test is a hard, red swelling occupying two thirds of the volar surface of the forearm, quite tender, and after four days only beginning to recede. This second reaction to the Schick test is more severe than the first. Are they to be considered still susceptible to diphtheria? Should more toxin-antitoxin be given? Would this reaction be considered evidence of allergy? Please omit name. M.D., Michigan.

ANSWER.—The reaction described is probably a pseudoreaction. As a rule a pseudoreaction develops quickly with more swelling than in the true reaction and fades quickly, disappearing usually in two or three days. The true reaction develops more slowly, reaches its height in two or three days, and fades gradually, so that some redness usually remains at the end of a week. The redness fades gradually, [illegible] there remains a brownish area over which a slight scaling is common. There are instances in which the pseudoreactions are so confusing that it is difficult to decide whether or not a person is immune. In such cases, by means of the Römer test in guinea-pigs, it is possible to determine the amount of antitoxin in the individual's blood, and so to know whether this is at least 0.04 unit per cubic centimeter, which is needed for protection.

HAND DRYING LOTION

To the Editor:—Some teachers in an elementary school near here have asked me for a formula of a hand drying lotion to use, as they have to wash their hands so many times a day in water that is very hard

Alice S. Cutler, M.D., Los Angeles.

Answer.—A drying lotion may be made of:

	Gm. or Cc.
Powdered tragacanth	2
Glycerin	
Alcohol	āā 25
Rosewater	ad 120

The tragacanth is shaken with the mixture of alcohol and glycerin, coating the inside of the bottle and the stopper. Then the rose water is added in very small amounts, the mixture being shaken vigorously each time until all has been added. The lotion is allowed to stand for twenty-four hours. A very small amount of this lotion rubbed on the hands while they are yet moist will tend to prevent drying. If too much is used, a temporary stickiness will be experienced which, however, disappears when the hands become dry. Other perfumes may be used as desired.

Should this mixture be found too dehydrating because of the amount of glycerin present, the following formula, which appears on page 45 of the Technic of Medication, published by the American Medical Association, may be substituted:

	Gm. or Cc.
Oil of rose	0.05
Oil of lavender	0.10
Oil of bergamot	0.20
Tragacanth	5.00
Boric acid	15.00
Glycerin	15.00
Water, to make	1,000.00

PYELITIS IN PERNICIOUS ANEMIA

To the Editor:—In The Journal, Dec. 19, 1931, p. 1912, it is stated that "it is important to remember that infections, such as pyelitis, can inhibit the action of the active principle effective in pernicious anemia." Can you furnish references in the literature relative to this statement?

Edmond Bechtold, M.D., Belleville, Ill.

Answer.—Minot and Murphy in their original paper concerning the treatment of pernicious anemia with liver indicated that infection could inhibit the effectiveness of this treatment. Since then, a large number of papers concerning the effect of liver, liver extracts and other potent substances in pernicious anemia have described or commented on the fact that infection inhibits the effect of treatment. Synopses of a large number of these articles are given in the annual reviews concerning the blood in Nelson's Loose Leaf Medicine.

A few pertinent references are:

Minot, G. R., and Castle, W. B.: The Adequate Treatment of Anemia, *Ann. Int. Med.* **5**:159 (Aug.) 1931.

HYPERKERATOSIS

To the Editor:—A woman, aged 30, has been troubled for two years with cracking of the skin on the flexor surfaces of the hands (palms) and extensor surfaces (soles) of the feet, occurring at the last month of pregnancy; there is slight itching at times; a child of 4 years is beginning to have the same condition. I should appreciate advice as to diagnosis and subsequent treatment. Please omit name.

M.D., District of Columbia.

Answer.—This may be an acquired hyperkeratosis, the result of local irritation and excessive dryness of the skin. The fact that the same condition is developing in the child suggests the possibility of the rare form of congenital palmar and plantar keratoderma. The eczema may be secondary to an epidermophyton infection. Mildly stimulating ointments containing tar or salicylic acid (from 2 to 4 per cent) may be tried. Roentgen therapy in small doses, from one-eighth to one-fourth skin unit once weekly, is frequently successful.

Council on Medical Education and Hospitals

COMING EXAMINATIONS

American Board for Ophthalmic Examinations: New Orleans, May 9. Montreal, Sept. 19. Sec., Dr. William H. Wilder, 122 S. Michigan Ave., Chicago.

American Board of Obstetrics and Gynecology: Written examinations will be held in nineteen cities of the United States and Canada, March 26. The general, oral and clinical examination will be held in New Orleans, May 10. Sec., Dr. Paul Titus, 1015 Highland Building, Pittsburgh.

American Board of Otolaryngology: New Orleans, May 9. Sec., Dr. W. P. Wherry, 1500 Medical Arts Bldg., Omaha.

Arizona: Phoenix, April 5-6. Sec., Dr. B. M. Berger, 12 N. Central Ave., Phoenix.

Arkansas: *Basic Science.* Little Rock, May 2. Sec., Mr. Louis E. Gebauer, 1002 Donaghey Bldg., Little Rock. *Regular.* Little Rock, May 10-11. Sec., Dr. Sam J. Allbright, Searcy. *Eclectic.* Little Rock, May 10. Sec., Dr. Claude E. Laws, 803½ Garrison Ave., Fort Smith. *Homeopathic.* Little Rock, May 10. Sec., Dr. Allison A. Pringle, Eureka Springs.

Colorado: Denver, April 6-9. Sec., Dr. Wm. Whitridge Williams, 422 State Office Bldg., Denver.

Idaho: Boise, April 5. *Comm. of Law Enforcement, Hon. Emmitt* Pfost, Boise.

Illinois: Chicago, April 12-14. Supt., Mr. Paul B. Johnson, Springfield.

Minnesota: *Basic Science.* Minneapolis, April 5-6. Sec., Dr. J. C. McKinley, 125 Millard Hall, University of Minnesota, Minneapolis. *Regular.* Minneapolis, April 19-21. Sec., Dr. E. J. Engberg, 524 Lowry Bldg., St. Paul.

Montana: Helena, April 5. Sec., Dr. S. A. Cooney, Power Block, Helena.

Nebraska. *Basic Science.* Omaha, May 3-4. Dir., Mrs. Clark Perkins, *Lincoln.*

Nevada Carson City, May 2-4. Sec., Dr. Edward E. Hamer, Carson City.

New Mexico: Santa Fe, April 11. Sec., Dr. P. G. Cornish, Jr., 221 W. Central Ave., Albuquerque.

Rhode Island: Providence, April 7-8. Dir., Dr. Lester A. Round, 319 State Office Building, Providence.

Wisconsin: *Reciprocity.* Milwaukee, April 6. Sec., Dr. Robert E. Flynn, 315 State Bank Bldg., LaCrosse.

MEETING OF THE COUNCIL ON MEDICAL EDUCATION AND HOSPITALS

The Council on Medical Education and Hospitals met in connection with the Annual Congress on Medical Education, Medical Licensure and Hospitals at the Palmer House, Chicago, February 15 and 16.

Following are some of the transactions of the meeting:

The list of physicians specializing in pathology and in clinical pathology (401) and the list of physicians specializing in radiology (1001) have been under revision during the past year, and certain additions and removals were approved by vote of the Council. The Council approved changes in the "Essentials" for admission to these lists which under the revision places the emphasis on the qualifications of the specialist rather than on the laboratory.

The "Essentials of a Registered Hospital" were revised and adopted.

All of the foregoing revised "Essentials" will be submitted for publication in appropriate issues of The Journal.

Approval for internships and for residencies were granted as follows:

Hospitals Approved for Intern Training:

- Baptist State Hospital, Little Rock, Ark.
- Women and Children's Hospital, Chicago.
- Woodlawn Hospital, Chicago.
- Protestant Deaconess Hospital, Evansville, Ind.
- Norton Memorial Infirmary, Louisville, Ky.
- Leila Y. Post Montgomery Hospital, Battle Creek, Mich.
- St. Louis County Hospital, Clayton, Mo.
- Highsmith Hospital, Fayetteville, N. C.
- Davis Hospital, Statesville, N. C.
- St. Rita's Hospital, Lima, Ohio.
- St. Elizabeth's Hospital, Youngstown, Ohio.
- Misericordia Hospital, Milwaukee.
- St. Luke's Hospital, Milwaukee.

Hospitals Approved for Residencies in Specialties:

- Compton Sanitarium, Compton, Calif.
- Orthopaedic Hospital-School, Los Angeles.
- Cook County Tuberculosis Hospital, Oak Forest.
- Boehne Tuberculosis Hospital, Evansville, Ind.
- Central State Hospital, Indianapolis.

Community Hospital, Beloit, Kan.
Jackson Memorial, Boston Floating Hospital, Boston.
St. Mary's Hospital, Grand Rapids, Mich.
Sunshine Sanatorium, Grand Rapids, Mich.
Kalamazoo State Hospital, Kalamazoo, Mich.
Morgan Heights Sanatorium, Marquette, Mich.
Ypsilanti State Hospital, Ypsilanti, Mich.
St. Louis County Hospital, Clayton, Mo.
State Hospital No. 3, Nevada, Mo.
State Hospital No. 2, St. Joseph, Mo.
Grasslands Hospital, Valhalla, N. Y.
City-County Hospital, Fort Worth, Texas.
Hermann Hospital, Houston, Texas.
St. Joseph's Hospital, Milwaukee.

The Council adopted the policy of having hospitals personally examined for registration as well as for approval, as far as resources permit. Changes in the Register, affecting the status of certain hospitals, were presented to the Council and adopted. These changes are based on personal visits and other means of communication with the hospitals.

Nebraska November Examination

Mrs. Clark Perkins, director, Bureau of Examining Boards, Nebraska Department of Public Welfare, reports the written examination held at Lincoln, Nov. 23-24, 1931. The examination covered 10 subjects and included 96 questions. An average of 75 per cent was required to pass. Ten candidates were examined, all of whom passed. The following colleges were represented:

PASSED

College	Year Grad.	Per Cent
State University of Iowa College of Medicine	(1930)	85.2
Creighton University School of Med..(1930) 77.5, 87,	(1931)	86.8
University of Nebraska College of Medicine	(1929)	84.4, (1931) 79.3, 80.6, 81.4, 81.8, 84.9

Mrs. Perkins also reports 6 physicians licensed by reciprocity with other states and 2 physicians licensed by endorsement from July 27 to Nov. 6, 1931. The following colleges were represented:

LICENSED BY RECIPROCITY

College	Year Grad.	Reciprocity with
State University of Iowa College of Medicine	(1927)	Iowa
Creighton University School of Medicine	(1929)	Kansas
University of Nebraska College of Med.	(1929)	Michigan, Montana
University of Pittsburgh School of Medicine	(1926)	Penna.
University of Wurzburg Faculty of Medicine	(1922)	Iowa

LICENSED BY ENDORSEMENT

College	Year Grad.	Endorsement of
Harvard University Medical School	(1929)	N. B. M. Ex.
University of Nebraska College of Medicine	(1930)	N. B. M. Ex.

Wisconsin October Report

Dr. Robert E. Flynn, secretary, Wisconsin State Board of Medical Examiners, reports 8 physicians licensed by examination, 35 physicians licensed by reciprocity with other states and 2 physicians licensed by endorsement of credentials at a meeting held in Milwaukee, Oct. 21, 1931. The following colleges were represented:

LICENSED BY EXAMINATION

College	Year Grad.	Number Examined
Northwestern University Medical School	(1931)	1
Marquette University School of Medicine	(1931, 5)	5
University of Wisconsin Medical School	(1929), (1930)	2

LICENSED BY RECIPROCITY

College	Year Grad.	Reciprocity with
Chicago College of Medicine and Surgery	(1916)	Illinois
Loyola University School of Medicine	(1930)	Illinois
Northwestern Univ. Med. School	(1916), (1930), (1931, 3)	Illinois
Rush Med. College....(1915) Iowa, (1924) N. Dakota,	(1929)	California, (1929), (1931) Illinois
University of Illinois College of Medicine	(1929), (1930)	Illinois
Indiana University School of Medicine	(1921), (1930)	Indiana
Harvard University Medical School	(1915)	Minnesota
University of Michigan Medical School	(1928), (1929, 2)	Michigan
University of Minnesota Medical School	(1930, 2) (1931)	Minnesota
St. Louis University School of Medicine	(1920)	Iowa
Washington University School of Medicine	(1929, 2)	Missouri
Creighton University School of Medicine	(1927)	Nebraska
University of Nebraska College of Medicine	(1930)	Louisiana
University of Buffalo School of Medicine	(1917)*	New York
University of Wisconsin Medical School	(1929)	Kansas, Utah, (1930) Missouri
Dalhousie University Faculty of Medicine	(1926)	Minnesota
University of Toronto Faculty of Medicine	(1924)*	Minnesota
University of Göttingen Faculty of Medicine	(1923)*	New York

Book Notices

Fundamentals of Orthopædic Surgery in General Medicine and Surgery (Harvard Lectures). By Robert B. Osgood, M.D., F.A.C.S., Consulting Surgeon, Boston Children's Hospital, and Nathaniel Allison, M.D., F.A.C.S., Professor of Surgery in Charge of the Division of Orthopædic Surgery, University of Chicago. Cloth. Price, $3. Pp. 311. New York: Macmillan Company, 1931.

The purpose of this collection of lectures, by two leading orthopedic surgeons, is to make available to the advanced medical student and general practitioner information as to the diagnosis and the immediate treatment of diseases and lesions falling in the domain of orthopedic surgery. The authors emphasize those contacts between orthopedic surgery and general medicine and general surgery which every physician encounters. The subject matter should enable the practitioner to apply intelligent "first aid" and to recognize the nature of the lesion or the presence of the underlying disease.

The authors became convinced eight years ago that the purely didactic lecture was inefficient. For six years with several rewritings they have presented these lectures to the students. They believe that in the four year medical course the student should be taught only enough of the recognized specialties of medicine and surgery to enable him to meet the demands of general practice with intelligence and safety. They believe that full class exercises in a specialty should include such teachings in the fundamentals as well enable the practitioner to make reasonably accurate diagnoses and recognize certain conditions which demand immediate and appropriate treatment. These exercises should be supplemented by clinical work with small sections. The lectures were written as clearly and simply as possible, with a few contributory references for those who desire more detailed information. They express their acknowledgment of indebtedness to the late Dr. Robert W. Lovett, much of whose thought and some of whose actual writings are included in the text.

The lectures were separately mimeographed and delivered to each student one week before the whole class exercise at which the subject was to be discussed. The students were requested to read each lecture before coming to the exercise, take whatever notes they desired, and hand the signed copies back before the given exercise.

The hour of the exercise was divided into three periods of approximately twenty minutes each. The first period was called the visual approach, the second period the deductive approach, and the third period the eductive approach. During the first period the subject was amplified by the exhibition of illustrative clinical cases, pathologic specimens and lantern slides. During the second period the students were permitted to ask the lecturer questions concerning the previous written lecture and clinical demonstration. During the third period the instructor selected students at random from a class list, quizzed them on information contained in the written lecture, and gave them an approximate mark on their answers.

They believe that a surgical specialty such as orthopedic surgery should always be considered as a part of general surgery. It should be based on and strictly follow the principles that govern general surgery. They state that orthopedic surgery includes the congenital and acquired deformities of the skeleton, certain diseases and injuries of the bones and joints, certain disturbances of the neuromuscular mechanism of the body, and static disabilities and deformities. The prevention and correction of deformity and disability in the motor mechanics of the body is a recognized field of orthopedic surgery.

The twelve lectures include general joint phenomena; the reactions of developmental and adult bone, nutritional and growth disturbances; congenital deformities, cerebral and spastic palsy; obstetric paralysis; Volkmann's deformity and Dupuytren's contracture; scoliosis; tuberculosis; anterior poliomyelitis; chronic rheumatic arthritis; traumatic disorders of joints and bursae; the relation of orthopedic surgery to industry and body mechanics and statics.

The three main causes for tissue changes in the bones and joints, including trauma, infection and toxins, are outlined. Joints react to irritation by synovial hyperemia, swelling, increased joint fluid and loss of function. Arthritis is divided into type I, atrophic arthritis, and type II, hypertrophic arthritis.

It is disappointing not to find brief descriptions of operations and the application of plaster-of-paris casts. These are given in other parts of the course. The subject of orthopedic surgery cannot be covered in twelve lectures; it requires about twenty sessions. One should discuss the question of supplementary operations, recumbent treatment, the application of plaster-of-paris technic and the use of braces and splints. Many orthopedic conditions are not covered in the lectures. The meager description of Osgood-Schlatter's disease, and especially the treatment, is disappointing. So is the short description of treatment of other types of epiphyseal disturbances. It is surprising that there is no mention of convalescent serum in the treatment of infantile paralysis even though it is not usually administered by the orthopedic surgeon. The description of treatment of apophysitis of the tibial tubercle is too short. There is an objection to the term "obstetrical paralysis" because of its similarity to the term "obstetrician." No mention is made of Kanavel's important work on Dupuytren's contracture.

In the lecture on poliomyelitis, the authors state definitely that the orthopedic surgeon has no part to play in the first few days of the disorder before paralytic symptoms appear. This conception is not universally held.

When one considers the authoritative writings of the two authors, one expects to learn from this book the last word on such subjects as upper tibial epiphysitis, bursitis in the region of the elbow, and arthritis, which are the pet subjects of the senior author; and general orthopedic pathology, tuberculosis of the knee, and atrophy of bone and synovial fluid, which are the favorite subjects of the junior author.

The book presents an interesting pedagogic experiment. It would be interesting to hear the comments of the medical students comparing these with lectures in other subjects. The brief historical notes serve to increase the interest in the subject. A short bibliography is appended to each chapter. The publisher's work is good. The book should be of value to interns and general practitioners and may well serve as a guide to teachers of orthopedic surgery.

Ein bewegtes Gelehrtenleben: Erinnerungen und Erlebnisse. Kämpfe und Gedanken. Von Otto Lubarsch. Paper. Price, 18 marks. Pp. 606, with a portrait Berlin: Julius Springer, 1931.

"What a battle!" might well epitomize this work, in which Lubarsch reveals his reaction to his environment; his motives, his weaknesses, his triumphs. It is more than sturdy independence that brought him into conflict at almost every point of contact—a strong sense of justice, a feeling for the underdog, perhaps a sharpened sensitivity, all contributed. By inheritance he has an understanding for the Semitic, by environment and education a love for the Germanic, by profession an appreciation of the international point of view on many subjects; such backgrounds for a strong personality inevitably lead the possessor into acute situations—situations which might not even arise for an individual of simpler pattern and, if encountered, ordinarily circumvented. Lubarsch seems never to have compromised. That in itself is genuinely refreshing to those who may be surfeited on our vaunted ability to compromise and keep things political, academic, industrial, running "smoothly" in America. Lubarsch would never have been recommended as a pathologist by any of our foundations. It speaks well for Althoff (the influential adviser for medical affairs in the ministry of education) that he repeatedly tried to put Lubarsch on the road to academic success despite his reputation as an *enfant terrible*. Althoff's support usually shattered on the resistance of individual faculties. As a matter of fact, it was twenty-three years from the time of his habilitation until he received his academic professorship at Kiel, although in the interim he held government appointments at Posen and at Düsseldorf. There is much of Virchow in Lubarsch, despite superficial dissimilarities. Both men were of indefatigable energy, were interested in social and political life, were interested in the fundamental problems of their profession, and uncompromising idealists. Virchow, of course, was an opponent of the aristocratic tradition in life because he saw about him the faults of too much aristocracy. Lubarsch has become an opponent of democracy because he sees the serious faults of too much democracy. Neither men concealed their point of view under academic robes. Lubarsch does not write much about his own work and that is perhaps as it should be. Others may do that well but no one can write of the mental reactions of Lubarsch, and this is done in so straightforward and honest a fashion that it becomes a really valuable document of the day. It is a lengthy record and not suited for rapid perusal, but the initiated will derive much pleasure. The pathologist who is interested only in pathology may find it tedious.

A Compendium of the Statute Law of Coroners and Medical Examiners in the United States. By George H. Weinmann, LL.B., Attorney and Counselor at Law. Issued under the Auspices of the Committee on Medicolegal Problems. Bulletin of the National Research Council, Number 83. Paper. Price, $3. Pp. 240. Washington, D. C.: National Research Council, 1931.

This is the third of a series of projects undertaken under the auspices of the committee on medicolegal problems of the National Research Council. The first was an investigation of the functioning of the offices of coroner and medical examiner, by O. T. Schultz and E. M. Morgan. The second was a survey of the law of the dead human body, by the author of the present study.

This volume brings together the laws relating to the coroner and medical examiner in the various jurisdictions of the United States. It considers these laws under the five main subject headings of selection, qualification, and tenure of office of the coroner; deputy coroners; powers and duties of the coroner; compensation and fees; and medical examiners. Under each heading the basic common law principles are briefly discussed, the relevant legislative enactments in each jurisdiction are quoted, and court decisions that have modified or defined the common law or statutory provisions are cited.

The office of coroner has been established by the state constitution of some states and by legislative enactment in other states. Although the office seems to be considered sacrosanct by some, the coroner is not an indispensable official. Even in states that have not replaced him by the medical examiner, the duties of coroner may be performed by justices of the peace, as in Arizona and Florida, or by the county attorney, as in Nebraska and Washington.

No qualifications, other than those of the ordinary voter, are required of the coroner in most states. A few specify that he shall not practice law while serving as coroner. In Louisiana and Virginia the coroner must be a physician qualified to practice medicine. In Michigan, medical qualifications are required of the coroners of counties with a population of 250,000 or more, in Ohio in counties of 100,000 or over. The Alabama code contains the curious provisions that any qualified elector may be coroner of a county with a population of 200,000 or more, but that in counties with from 95,000 to 195,000 inhabitants the coroner must be a physician.

The most important magisterial duty of the coroner is the holding of inquests. Deaths that must be referred to the coroner in general fall into two distinct groups, namely, those due to violence, and sudden deaths of persons not attended before death by a licensed physician. In the holding of inquests the coroner is limited by the statutes of practically all states to deaths presumably due to violence. Some states make still further restrictions, in that death must be due to the violence of another, or must presumably be felonious in character, or must not be due to casualty. In certain states (Iowa and Missouri) the coroner is required to hold an inquest in nonviolent deaths if an inquest is requested by the relatives; the latter, however, become responsible for the costs of the proceeding if death is found not to have been due to violence. In Connecticut, New York, Oregon and Rhode Island the coroner holds antemortem inquests in the case of those seriously wounded by another.

Whereas the holding of the inquest is the most important magisterial or legal duty of the coroner's office, the performance of necropsy for the purpose of determining the cause of death is the important medical function of the office. The statutes and court decisions quoted establish quite clearly that the coroner has no authority to perform or order a necropsy in any given instance unless he has the power to hold an inquest on the body. The coroner's office, therefore, has only limited value as an agency for the determination of causes of death, since in most jurisdictions half or more than half of the deaths referred to the coroner are not due to violence.

The final section quotes fully the laws of those jurisdictions that use the medical examiner system. In his opening paragraph, as well as in a concluding one, Weinmann intimates that these laws have merely changed the name of an official from coroner to medical examiner. This is a view that many members of the legal profession seem to hold. But it will be apparent to any one who reads the medical examiner acts of Massachusetts, New Jersey and New York that these laws do more than merely make a change in name. They replace an antiquated system, incapable of adapting itself to modern conditions, by a mode of procedure that recognizes the importance of the medical duties that the coroner should perform. They define the duties of the medical examiner much more precisely than does any law relating to the coroner, and they transfer the magisterial duties to existing agencies of justice much better qualified to perform those duties than is the coroner's office. The New Jersey act of 1927 should serve as a model to any community that proposes to take this forward step.

In discussing the admissibility in evidence of the medical examiner's necropsy report, Weinmann says that such a document is not admissible "in the absence of a statute expressly making such report admissible. At the present writing, however, there appears to be no such statute." The second paragraph of section 6 of the New Jersey act, quoted by Weinmann on page 220, does expressly provide that the records of the medical examiner or certified transcripts thereof "shall be received as evidence in any court in this state of the matters and facts therein contained."

Reform of the coroner's office should receive much more serious attention than it does receive. Weinmann has done a service of great value in bringing together the laws relating to the office. The student of the medicolegal problems presented by the coroner's office obtains a much better grasp of the subject than has heretofore been possible. The leader of public opinion who may desire to direct that opinion along a line that will prove beneficial to society will find the volume useful. It is recommended to the medical and legal professions as a store of information on a subject concerning which most of the members of those professions have little accurate knowledge. A subject index and a geographic index make reference easy.

Praktische Differentialdiagnostik für Ärzte und Studierende. Herausgegeben von Professor Dr. Georg Honigmann. Band VII: Differentialdiagnostik in der Pädiatrie. Von Dr. med. Walter Pflüger, Facharzt für Kinderkrankheiten in Stuttgart. Mit einem Vorwort von Prof. Dr. med. Joseph Husler, Leiter des Kinderkrankenhauses München-Schwabing. Paper. Price, 11.50 marks. Pp. 160. Dresden: Theodor Steinkopff, 1931.

This is the seventh and concluding volume of a comprehensive work on practical differential diagnosis. The editor, Prof. Dr. Georg Honigmann, died before it was completed. The volume is edited by Dr. Walter Pflüger of Stuttgart and Prof. Dr. Joseph Husler of Munich. The book is a valuable addition to pediatric textbooks and is especially designed for the general practitioner and student rather than the specialist. The information regarding differential diagnosis is easily available and concise: in the chapter on the new-born, the differential diagnosis on the causes of asphyxia is discussed, then on the causes of convulsions, then icterus, swellings of the head, fever in the first week, bloody stools and hematemesis. Another example of the method of differentiation may be cited from the section on the kidney: disturbances in urine secretion are differentiated, cause of polyuria, causes of anuria, enuresis, differentiation of causes of bacteriuria, and pus in the urine, hematuria and hemoglobinuria. In the chapter on the exanthems the fine rashes, as scarlet fever, German measles, fourth disease, syphilis and sunburn, are differentiated. Then the coarser rashes are distinguished from one another, as measles, infectious erythema, urticaria and drug rashes. Then the exanthems with pustules, such as varicella, variola, pemphigus and impetigo, are differentiated. Most conditions are grouped and differentiated on the basis of symptoms or obvious manifestations revealed by physical or laboratory examination. The anemias, however, are differentiated on the basis of pathogenesis. The volume is well worth having in one's library.

The Wills Hospital of Philadelphia: The Influence of European and British Ophthalmology Upon It, and the Part It Played in the Last 100 Years in Developing Ophthalmology in America. By William Campbell Posey, B.A., M.D., Consulting Surgeon to the Hospital, and Samuel Horton Brown, M.D. Cloth. Price, $5. Pp. 340, with illustrations. Philadelphia: J. B. Lippincott Company, 1931.

To one who practices ophthalmology for the sake of ekeing out an existence, the purchase and reading of this book would be futile. But to the man who is interested in his profession, who has a pride in the development of American ophthalmology and who likes to be a bit of the yeast that ferments international ophthalmology, this book is a treat. As the subtitle says, it shows the influence of European and British ophthalmology on Wills Hospital and the part it played in the last hundred years in developing ophthalmology in America. The founding and history of the institution are taken up at length, together with a description of the old buildings and finally with the projected new building. Then there are short biographic sketches of the various surgeons who have been identified with the hospital. The instruction given by the hospital is touched on and its character is mutely vouched for by the list of former residents who are now making ophthalmologic history in this country. The various types of operations that have been and still are being performed at Wills are described, together with most illuminating historical comments. There follows then a list of books written since the inception of the hospital by various members of the staff. The spirit of Wills Eye Hospital is not mentioned, but it is that modest self-effacing spirit which made Wills Eye Hospital the cradle of American ophthalmology and that has guided American ophthalmology through the dangers of puberty and adolescence to the robust manhood it now presents. All credit is due to the chroniclers for the enormous amount of work the making of this book entailed and for the interesting presentation of material that all American ophthalmologists should know.

Lehrbuch der klinischen Untersuchungsmethoden für Studierende und praktische Ärzte. Band II, Hälfte 2. Von Prof. Dr. H. Sahli. Seventh edition. Paper. Price, 30 marks. Pp. 369-686, with illustrations. Leipzig: Franz Deuticke, 1931.

This section of the second volume of Sahli's revised textbook is divided into discussions of hematology, blood chemistry and serology. The treatment of the subject of hematology is handled in a refreshing manner. It is not a mere cataloguing of detailed facts but a clear and concise discussion of the principles, significance and interpretation of the data presented. The author has chosen the discourse method of presenting the subject and it is well executed. The necessity of rendering hematologic facts more dynamic is stressed, and overemphasis of the significance of changing blood pictures in infectious diseases is avoided. The chapters dealing with blood chemistry and serology are well covered but are not as up to date as some of the recent textbooks on the same subject. In general, the material is treated in a clear and concise manner and is well handled. The book is not recommended for those who possess only an elementary training in laboratory diagnosis, as much of the text presumes a familiarity with the subjects considered.

Heredity. By A. Franklin Shull, Professor of Zoölogy in the University of Michigan. Second edition. Cloth. Price, $3. Pp. 345, with 143 illustrations. New York: McGraw-Hill Book Company, Inc., 1931.

The first edition of this textbook, published in 1926, was intended to give a scientifically adequate presentation of the principles of genetics, and of the bearing of these on problems of human society, to readers who had no previous knowledge of the subject. It has been generally recognized to have been admirably successful in this aim. The second edition has been extensively revised. Certain rather technical subjects have been introduced because of recently demonstrated applications to human heredity. The discussion of heredity in man has been considerably enlarged and the discussion of population and the immigration question brought down to date. Problems have been introduced in the fundamental parts to increase the usefulness as a textbook. Numerous other minor changes have been made. One feature that deserves attention is the constant emphasis on the physiologic nature of the activity of the hereditary units. Research in genetics has been largely concentrated on the problem of the mechanism of transmission, and only recently has attention begun to be directed on problems of gene action. Characteristics have been looked on as merely more or less convenient indicators of the presence or absence of the ultimate units. In consequence, geneticists have often fallen into a loose way of speaking of particular genes as if they were representative of particular characters. It has been well known, of course, that gene and character are not related in any one-to-one fashion. Whatever the immediate effects of each gene may be, these have ramifying consequences which ultimately touch many physiologic processes, including ones of which organic structure may be a by-product. Each gene replacement in general has multiple effects and, conversely, any assignable characteristic is affected by many genes. Professor Shull is exceptionally successful in keeping this point of view before the reader and in giving due weight to environmental as well as genetic factors. The chapters on human heredity have been carefully written Characters such as eye color and feeblemindedness, which have seen long service in elementary books as examples of simple mendelian heredity, on the basis of early work, are discussed in the light of the complexity revealed by more recent researches.

Alte und neuzeitliche Ernährungsfragen unter Mitberücksichtigung wirtschaftlicher Gesichtspunkte. Von Professor Dr. Carl v Noorden, Geheimer Medizinalrat, Vorstand der Sonderabteilung für Stoffwechselstörungen und diätetische Heilmethoden des Krankenhauses der Stadt Wien. Paper. Price, 6.90 marks. Pp. 117. Berlin. Julius Springer, 1931.

This small volume is not intended to be a comprehensive work on nutrition. It is rather a critical analysis of a few phases of this subject, from a chiefly practical standpoint, and in a general rather than detailed manner. The material presented includes several chapters on the influence of diet on the acid-base balance and the mineral metabolism in man. One chapter is devoted to the place of uncooked foods in the dietary, and another to miscellaneous subjects such as adequate protein intake, the use of rye bread, coffee and substitutes for it, and vitamins. The author considers these subjects from two distinct standpoints: first, the national or racial dietary and, second, the therapeutic diet. The practical bearing of his discussion of the national dietary is, like his bibliography, almost entirely German. His observations on therapeutic diets have a much wider application. The author points out the influence of modern transportation, commercial methods, and fashions in cooking on the German dietary. He emphasizes the fact that the diet of a people or a country embodies a great deal of practical experience and is not to be tampered with lightly. He indicates certain precautionary measures that ought to be taken to keep the German dietary wholesome. While admitting and enlarging on the value of certain special diets in disease, the author deprecates the overenthusiastic application of such knowledge to the diet of the normal individual. He sounds the warning that the tried and proved dietary knowledge of the past should not be forgotten or discarded for a passing fad. He concludes that one may work harm as well as benefit by diet and that it behooves the physician to choose with care. This book hardly answers the purpose of the physician seeking a collection of dietary formulas or specific advice as to the dietary management of disease. Its breadth of outlook and maturity of judgment, however, should make it well worth the reading for those whose special interests lie in the field of dietetics and nutrition.

Evolution of Facial Musculature and Facial Expression. By Ernst Huber, Ph.D., M.D., Associate Professor of Anatomy, the Johns Hopkins University. Cloth. Price, $2.50. Pp. 184, with 28 illustrations. Baltimore: The Johns Hopkins Press, 1931.

Facial expression, momentary or permanent, plays a prominent part in human intercourse. It indicates character and gives beauty and interest to the human countenance. It also gives it individuality; people's faces differ. Each race has its characteristic "face," as have horses and dogs; and many animals are capable of much facial expression. Huber has studied the anatomic mechanism that produces this expression. He has been especially interested in its evolution, its development during childhood, and racial differences in it. It evolves in the mammals from two superficial neck muscles, both visceral in origin: the platysma (originally nuchal in position) and the sphincter colli profundus. From the first are developed the muscles behind the ear in the lower lip and the platysma of the neck; from the second are developed some intrinsic muscles of the ear, the orbicularis oculi and associated muscles, the orbicularis oris and cheek muscles and the vibrissae movers. All these muscles are characteristic of mammals and become progressively better developed from the lower to the higher orders. In the lower each forms a common mass, plastic and susceptible of development in special parts for special purposes. In each human individual it is developed entirely after birth; there is no facial expression in the new-born baby. In the first four or five years the power of expression is developed, and in these early years it works automatically. The facial expression of little children is always honest; in later life it may be intentionally inhibited by control from the cortex of the brain. This control, nonexistent in children, is susceptible of much development through practice. It is interesting to note that Huber believes that convincing facial expression must always be honest and that the only way in which great actors are able to play their emotional parts successfully is by really experiencing the emotions they seek to express. These muscles grow by exercise, accentuating the facial expressions they produce. In old age the face skin loses its elasticity: it tends to become fixed in a mask—not immovable but nevertheless a record of the prevailing emotions which have played over it through the years. The racial differences are studied in six races: White, Negro, Chinese, Hawaiian, Australian and Papua-Melanesian. They are illustrated by full page pictures, which are also assembled on one plate for comparison. Huber finds that evolution of the parts of the central nervous system which control them precedes the evolution of the facial muscles themselves. This adds strength to the view of those anatomists who believe that the central nervous system "is" the man and that the most direct study of his evolution lies in the study of the evolution of the brain. The subject is one of great interest and this publication is much the most important contribution to it that has been made in America.

Embonpoint et obésité: Conceptions et thérapeutiques actuelles. Par Jean Leray, médecin consultant à Brides-les-Bains. Préface du Dr. Chiray. Paper. Price, 20 francs. Pp. 195 Paris: Masson & Cie, 1931.

This book contains practically all the information now available on the subject of obesity. It is well put together, particularly from the clinical point of view. The pathologic and etiologic classifications might not be accepted by every one, but on the whole the book serves as an excellent review of current knowledge. It is interesting to note that almost all the literature on this subject is of recent date and includes at least some of the more important American contributions. Newburgh's latest publications are apparently too recent to be included.

Imhotep to Harvey: Backgrounds of Medical History. By C. N. B. Camac, M.D., Assistant Professor of Clinical Medicine, College of Physicians and Surgeons, Columbia University. Foreword by Henry Fairfield Osborn, Sc.D., LL.D. Cloth. Price, $3.75. Pp. 321, with 4 illustrations. New York: Paul B. Hoeber, Inc., 1931.

The notes included in this volume have been used by the author in conducting seminars in medical history in Columbia University. The classes consisted of from ten to fifteen fourth year medical students. In these seminars the associated material used is spread on a large table; the students examine the exhibits and confer concerning them. Thus medical history is made living and attractive. The book serves, therefore, as an outline of medical history from the earliest times to the end of the seventeenth century. It also provides a discussion of various schools of thought. There is an essay on the meaning of the emblem of medicine and the book includes some reprints of important historical documents of great scientific interest. Special appendixes provide chronological tables and a good bibliography. The book is handsomely printed, as are all the medical contributions which come from Mr. Hoeber's press.

A Psychiatrist's Anthology. By Louis J. Karnosh. Boards. Price, $4. Pp 36, with illustrations Cleveland: Occupational Therapy Press, 1931.

This is an artistic contribution printed by the Occupational Therapy Press. There are only 168 copies available. The book is a literary curiosity, as any volume of poems which includes words like "diencephalon" and "presbyophrenia" would have to be. The illustrations exemplify the disordered mind; the prose represents the moods of the insane. The book should be of special interest to collectors and to psychiatrists.

A Dictionary of Terms Dealing with Disorders of Speech. A Temporary and Incomplete Edition Published in Order to Invite Criticism and More Adequate Definitions, Prior to Publication of a Later Edition, to be Based on Further Study. Compiled by Samuel D. Robbins, A.M., Director, Boston Stammerers' Institute, and Sara M. Stinchfield, Ph.D., Associate Professor of Psychology, Mount Holyoke College, Members of the Nomenclature Committee of the American Society for the Study of Disorders of Speech. Paper. Pp. 27. Boston: American Society for the Study of Disorders of Speech, 1931.

This booklet, prepared under the auspices of the American Society for the Study of Disorders of Speech, is developed primarily to provide a standard nomenclature for workers in this field. Obviously the authors have given most serious consideration to the subject and are not willing to assume that they have said the last word that is to be said about it. They are willing to accept additions and corrections with a view to the eventual publication of an international edition.

Die Allgemeinerscheinungen der Hirngeschwülste. Von F. Kehrer, o. ö. Professor und Direktor des Psychiatrischen- und Nervenklinik, Münster i.W. Paper. Price, 10 50 marks. Pp. 116, with 11 illustrations. Leipzig: Georg Thieme, 1931.

This monograph probably clarifies the diagnosis of brain tumors in the author's own mind much more than it adds anything to the knowledge of intracranial tumors. He has repeated many things that have been well known in this country for several years. In an attempt to add new material he has placed considerable stress on the finding of increased pain responses and reflexes, particularly over the face, head and extremities, in intracranial tumors. He has stated that there is an elevated pain threshold in the presence of an altered physiologic action in the brain. Whereas clinical observations are always of value, it would seem that these are a bit far fetched; and they are no real contribution to the diagnosis of intracranial tumors.

Your Health and Your Earning Power: A Book Prepared for the Use of the Employees of the Electric Light and Power Industry. Cloth. Price, 65 cents. Pp. 181, with illustrations. New York: National Electric Light Association, 1931.

This book was prepared for the employees of the electric light and power industry through the National Electric Light Association. All the chapters that it contains have been prepared by competent workers through the Committee on Health Promotion and First Aid of the association. The book is essentially a guide to hygiene written in simple language. It covers briefly knowledge of anatomy, physiology, diet, living habits, personal hygiene and disease prevention, first aid in sickness, home nursing and first aid to the injured. The material is reliable.

Books for Tired Eyes: A List of Books in Large Print. Compiled by Charlotte Matson, Minneapolis Public Library. Second edition. Paper. Pp. 58. Chicago: American Library Association, 1931.

The American Library Association has done a valuable service in making available a list of books printed in large type for readers who need that type of book. All the books in the list are printed in type as large as 14 point; some of them are in type as large as 24 point. The books are classified as fiction, with subclassifications, biography, travel and general literature. There is also a list of books for young people.

Quacks. By Charles W. Warner. Cloth. Price, $1. Pp. 206. Jackson, Mississippi: The Author, 1930.

The author has for many years been associated with the sale of various books and publications to physicians. He writes as a thorough friend of the profession. Most of his material has been taken from easily available sources. The writing is "rough and ready" and will, no doubt, afford both interest and amusement to every medical reader. The author has also arranged to provide individual chapters in the form of pamphlets to those who wish to extend his circulation.

Woman's Coming of Age: A Symposium. Edited by Samuel D. Schmalhausen and V. F. Calverton. Cloth. Price, $3.75. Pp. 569. New York: Horace Liveright, Inc., 1931.

This volume is a symposium presented largely by advanced thinkers on the subject of women. The writing is interesting and thought provoking throughout. From personal experiences, many readers will find much on which they differ with those who write. Of particular interest to the physician is part two, which deals with psychology and pathology of the sexes, including particularly the articles entitled "What the Clinic Reveals," by Carrie Weaver Smith; "The Emotional Life of Modern Women," by G. V. Hamilton; "Woman's Sexual Nature," by Havelock Ellis, and "The Struggle Against Childbearing," by Herbert Aptekar. Other parts of the book deal with women through the ages, the new woman, and problems and projects. The book includes twenty-eight essays and an introduction, concluding with biographic outlines of the lives of the contributors.

Medicolegal

Accident Insurance and Death from Carbon Monoxide

(Miller v. Inter-Ocean Casualty Co. (W. Va.), 158 S. E. 706)

On Dec. 16, 1928, the automobile which Miller was driving became hopelessly mired. The evening was damp and cold. Miller's two companions proceeded afoot, while he remained with the car in anticipation of the arrival of a team of horses which passers-by had promised to send to pull the car out of the mud. Miller, while waiting, was to repair a tire which had blown out. The following morning, Miller was found dead in the car. The engine was running and the windows were closed. The tire had not been repaired. The physician who examined the body found the lips a pink color and a "cherry blush" on the cheeks, instead of the usual pallor of death. He diagnosed the case as one of carbon monoxide poisoning. Miller was insured against the effects of bodily injury caused directly, exclusively, and independently of all other causes by external, violent, and accidental means, "which bodily injury is sustained by the insured in (1) automobile accidents, while operating, driving, riding in or on, . . . an automobile." The insurer, however, refused payment, and Miller's widow, the beneficiary under the policy, instituted suit. From a judgment in favor of the widow, the insurer appealed to the Supreme Court of Appeals of West Virginia, where the judgment of the trial court was affirmed.

In response to the insurer's contention that the deceased "was not operating his automobile within the meaning of the policy at the time he was affected by the carbon monoxide gas," the court cited with approval a North Dakota decision in a similar case:

> "To exclude the inhalation of carbon monoxide gas during a period when the car is stalled in a mudhole on the theory that motion had ceased would be not merely to adopt a narrow meaning of the language of the contract, but to actually deprive the words used of a portion of their ordinary meaning. The occupant of a car while it is stalled in a mudhole, particularly during a time when means of escape in comfort may well appear to be lacking, is still riding in the car in quite the same sense as a passenger upon a steamship at anchor may be riding the waves." *Johnson v. Fed. Life Insurance Co.*, 234 N. W. 661.

The insurer contended further that death was not the result of bodily injury caused by accidental means, within the meaning of the policy. With that contention, however, the Supreme Court of Appeals did not agree. The term "accidental means," said the court, has been variously defined, and the court accepted the view that an effect which is not the natural or probable consequence of the means which produced it, which does not ordinarily follow and cannot be reasonably anticipated from the use of those means, which the actor did not intend to produce, and which he cannot be charged with the design of producing under the maxim that every man must be held to intend the natural and probable consequence of his deeds, is produced by accidental means.—*Western Commercial Travelers' Association* v. *Smith*, (C. C. A.) 85 Fed. 401, 40 L. R. A. 653.

The court furthermore would not accept the contention of the insurer that Miller voluntarily exposed himself to the danger which caused his death. The odorless and tasteless nature of the insidious monoxide gas, said the court, prevents any intimation that the insured knowingly remained in a place of danger. While it is true that without the engine running, no carbon monoxide would have been produced, and that to the extent that Miller started the car and closed the windows his acts were voluntary, yet without some intervening factor the natural and probable consequences of his acts would have produced no danger. That intervening factor was the proximity of the exhaust pipe to the ground, causing the poisonous gas to come into the car—which produced the unnatural condition and danger, a factor which cannot be attributed to the deceased and which was not one that occurs or is anticipated in the ordinary course of events under similar circumstances.

Workmen's Compensation Acts: Complications Following Industrial Accident Compensable.—The plaintiff, in the course of his employment, strained a sacro-iliac joint. Infection followed this strain, and complications arose in the sacro-iliac region, prolonging the disease and aggravating the plaintiff's condition. Ten physicians who testified concurred in the opinion that the plaintiff's condition had become worse because he had not received proper treatment immediately after the accident; that a strain of the sacro-iliac joint usually should be cured within a month or two, if properly treated and the patient made to rest; and that the plaintiff's condition at the time of the trial was such that he could not perform manual labor. On behalf of the defendant it was contended that the evidence did not establish that the injury to the plaintiff was the result of an accident occurring out of and in the course of his employment. We are of the opinion, said the court of appeal of Louisiana, second circuit, second division, that the evidence does establish with legal certainty that the plaintiff's condition is traceable to a strain sustained by him in the course of his employment. It is probably true that his continued disability has been contributed to by diseases independent of, or possibly connected with, the original injury, causing prolongation of the ailment and slowness of recovery. However, even if that is true, the right to recover compensation will not be unfavorably affected thereby. It is not necessary, in order to recover under the employers' liability act of Louisiana, that the continued disability resulted directly from the injury. It is sufficient if the disability is the result of a condition arising from the injury, or that the injury is a contributing cause of the disability.—*Anderson v. Louisiana Oil Refining Corporation (La.), 134 So. 343.*

Workmen's Compensation Acts: Right of Employee to Sue for Injury Due to Occupational Disease.—The plaintiff alleged that the disease of the lungs from which he suffered was due to the inhalation of particles of steel in the course of his employment. He attributed the inhalation of such particles to the failure of his employer to provide proper safeguards to protect its employees. Since the condition from which he suffered was admittedly not compensable under the workmen's compensation act of New Jersey, he brought suit against his employer, at common law, to recover damages. His employer, the defendant in this case, contended that it was the intent of the legislature to provide compensation for only the accidents and occupational diseases described in the statutes, and not only to exclude all other occupational diseases from compensation under the workmen's compensation act, but also to preclude a person from instituting an action at law to recover damages for an occupational disease not described in it. But, said the circuit court of New Jersey, Hudson county, if the legislature had intended to bar an action at common law for an occupational disease contracted through the negligence of an employer, it would have said so. The contention of the employer was therefore overruled.—*Szalkowski v. C. S. Osborne & Co. (N. J.), 154 Atl. 611.*

Privileged Communications: When Privilege Is Waived.—By the weight of authority, according to the Supreme Court of Oklahoma, the right to waive the benefit of a privileged communication statute survives a patient and may be exercised after his death by the beneficiary named in an insurance policy on the life of the deceased. The fact, however, that the beneficiary calls as a witness a physician who treated the deceased does not operate as a waiver of the privilege as to other physicians who treated him at other times, even though they attended him for the very ailment concerning which the physician called as a witness testified. The privilege is waived when the plaintiff testifies to the results of a particular examination by a physician, in which case the defendant may call the physician who made the examination, to corroborate or disprove the testimony of the plaintiff. It is waived, too, when two or more physicians in consultation examine the patient, and one of the examining physicians is called to testify concerning the results of the examination, in which case any other physician who took part in the same examination may be called by the opposing party. But if the physician whose evidence is proffered by the opposing party made his examination at a different time, and the plaintiff himself has not testified concerning the results of the examination made by the proffered witness, the evidence of that witness is inadmissible.—*United States Nat'l Life & Casualty Co. v. Heard (Okla.), 298 P. 619.*

Society Proceedings

COMING MEETINGS

American Medical Association, New Orleans, May 9-13. Dr. Olin West, 535 North Dearborn Street, Chicago, Secretary.

Alabama, Medical Association of the State of, Mobile, April 19-22. Dr. D. L. Cannon, 519 Dexter Avenue, Montgomery, Secretary.
American Association for Thoracic Surgery, Ann Arbor, Mich., April 18-20. Dr. Duff S. Allen, 3720 Washington Blvd., St. Louis, Sec'y.
American Association of Anatomists, New York, March 24-26. Dr. George W. Corner, University of Rochester School of Medicine, Rochester, N. Y., Secretary
American Association of Pathologists and Bacteriologists, Philadelphia, April 28-29. Dr. Howard T. Karsner, 2085 Adelbert Road, Cleveland, Secretary.
American Association of Physical Anthropologists, Washington, D. C., March 21-23. Dr. D. J. Morton, 632 W. 168th St., New York, Sec'y.
American Climatological and Clinical Association, Atlantic City, May 5-7. Dr. Arthur K. Stone, Auburn Street, Framingham Center, Mass., Secretary.
American College of Physicians, San Francisco, April 4-8. Mr. E. R. Loveland, 133 South 36th Street, Philadelphia, Executive Secretary.
American Dermatological Association, Havana, Cuba, May 3-5. Dr. William H. Guy, 500 Penn Avenue, Pittsburgh, Secretary.
American Gastro-Enterological Association, Atlantic City, May 2-3. Dr. Charles G. Lucas, 307 West Broadway, Louisville, Secretary.
American Heart Association, New Orleans, May 10. Dr. Irl C. Riggin, 450 Seventh Avenue, New York, Executive Secretary.
American Physiological Society, Philadelphia, April 28-30. Dr. Arno B. Luckhardt, 5216 Greenwood Avenue, Chicago, Secretary.
American Proctologic Society, Memphis, May 6-7. Dr. Curtice Rosser, 710 Medical Arts Building, Dallas, Texas, Secretary.
American Society for Clinical Investigation, Atlantic City, May 2. Dr. Cyrus C. Sturgis, Simpson Memorial Institute, Ann Arbor, Mich., Secretary.
American Society for Experimental Pathology, Philadelphia, April 28-30. Dr. C. Phillip Miller, Jr., University of Chicago, Chicago, Secretary.
American Society for Pharmacology and Experimental Therapeutics, Philadelphia, April 27-30. Dr. V. E. Henderson, University of Toronto, Toronto, Secretary.
American Society of Biological Chemistry, Philadelphia, April 28-30. Dr. H. B. Lewis, University of Michigan Medical School, Ann Arbor, Secretary
American Society of Clinical Pathologists, New Orleans, May 6-9. Dr. A. S. Giordano, 531 North Main Street, South Bend, Ind., Secretary.
Arizona State Medical Association, Globe, April 21-23. Dr. D. F. Harbridge, 407 Goodrich Building, Phoenix, Secretary.
Arkansas Medical Society, Little Rock, April 5-7. Dr. William R. Bathurst, 814 Boyle Building, Little Rock, Secretary.
Association for the Study of Internal Secretions, New Orleans, May 9-10. Dr. F. M. Pottenger, 1930 Wilshire Boulevard, Los Angeles, Secretary.
Association of American Physicians, Atlantic City, May 3-4. Dr. James H. Means, Massachusetts General Hospital, Boston, Secretary.
California Medical Association, Pasadena, May 2-5. Dr. Emma W. Pope, 450 Sutter Street, San Francisco, Secretary.
District of Columbia, Medical Society of the, Washington, D. C., May 4-5. Dr. C. B. Conklin, 1718 M Street, N. W., Washington, D. C., Secretary.
Florida Medical Association, Sarasota, May 3-4. Dr. Shaler Richardson, 111 West Adams Street, Jacksonville, Secretary.
Iowa State Medical Society, Sioux City, May 4-6. Dr. Robert L. Parker, 3510 Sixth Avenue, Des Moines, Secretary.
Kansas Medical Society, Kansas City, May 3-5. Dr. J. F. Hassig, 804 Huron Building, Kansas City, Secretary.
Louisiana State Medical Society, New Orleans, May 9-10. Dr. P. T. Talbot, 1430 Tulane Avenue, New Orleans, Secretary.
Maryland, Medical and Chirurgical Faculty of, Baltimore, April 26-27. Dr. Walter Dent Wise, 1211 Cathedral Street, Baltimore, Secretary.
Medical Society of the Missouri Valley, Omaha, Neb., March 29-31. Dr. Joseph D. McCarthy, 107 South 17th Street, Omaha, Secretary.
Medical Women's National Association, New Orleans, May 8-9. Dr. Sylvia Allan, Winthrop College, Rock Hill, S. C., Secretary.
Mississippi State Medical Association, Jackson, April 12-14. Dr. T. M. Dye, Clarksdale, Secretary.
North Carolina, Medical Society of the State of, Winston-Salem, April 18-20. Dr. L. B. McBrayer, Southern Pines, Secretary.
Ohio State Medical Association, Dayton, May 3-4. Mr. Don K. Martin, 131 East State Street, Columbus, Executive Secretary.
South Carolina Medical Association, Columbia, April 19-21. Dr. E. A. Hines, Seneca, Secretary.
Tennessee State Medical Association, Memphis, April 12-14. Dr. H. H. Shoulders, 706 Church Street, Nashville, Secretary.
Texas, State Medical Association of, Waco, May 5-7. Dr. Holman Taylor, Medical Arts Building, Fort Worth, Secretary.

Current Medical Literature

AMERICAN

The Association library lends periodicals to Fellows of the Association and to individual subscribers to The Journal in continental United States and Canada for a period of three days. Issues of periodicals are kept on file for a period of five years only. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 12 cents if two periodicals are requested). Periodicals published by the American Medical Association are not available for lending, but may be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

American Journal of Pathology, Boston

8: 1-121 (Jan.) 1932

*Renal Lesions in Toxemias of Pregnancy. E. T. Bell, Minneapolis.—p. 1.
Infectious Oral Papillomatosis of Dogs. W. A. DeMonbreun and E. W. Goodpasture, Nashville, Tenn.—p. 43.
*Tularemic Encephalitis: Pathology of Acute Tularemia with Brain Involvement and Coexisting Tuberculosis. F. W. Hartman, Detroit.—p. 57.
Study of Vaccine Virus Pneumonia in Rabbits. R. S. Muckenfuss, H. A. McCordock and J. S. Harter, St. Louis.—p. 63.
*Frequency of Anomalous Reticula in Right Atrium of Human Heart "Chiari Network": Eight Cases. F. C. Helwig, Kansas City, Mo.—p. 73.
Syphilitic Aortic Endocarditis and Superimposed Bacterial (Streptococcus Viridans) Endocarditis. E. B. Craven, Jr., Durham, N. C.—p. 81.
Quantitative Observations on Valves of Human Heart. P. Gross and R. A. Moore, Cleveland.—p. 91.
Formation of Bone Marrow in Suprarenal Gland. D. C. Collins, Rochester, Minn.—p. 97.
Multiple Infarcts and Necroses of Spleen (Fleckmilz). G. Rake, Heidelberg, Germany.—p. 107.
Tumors in Captive Primates: Two Cases. H. L. Ratcliffe, Philadelphia.—p. 117.

Renal Lesions in Toxemias of Pregnancy.—Bell states that in fatal cases of eclampsia a characteristic glomerular lesion is found. The glomeruli show a marked narrowing of all their capillaries, caused usually by an increase in thickness of the capillary basement membrane, but sometimes by an increase of endothelial cells. One case is reported in which the lesions resulting from an attack of eclampsia seven years before are described. These consisted of focal hyaline areas in the glomeruli with partial or complete glomerular obliteration and varying degrees of tubular atrophy. It is shown that a peculiar form of chronic renal disease may result from the eclamptic kidney. In one case of hyperemesis gravidarum, glomerular lesions were found which corresponded entirely to those of typical eclampsia. In three other cases the glomeruli were normal. A fatty liver without necroses is characteristic of this form of toxemia. When a woman with chronic renal disease becomes pregnant, there is usually an aggravation of all the nephritic symptoms. The condition cannot be distinguished from preeclampsia and eclampsia unless the condition of the kidneys prior to pregnancy is known, or unless there is a definite impairment of renal function. Women with chronic nephritis do not show a special tendency to develop gestation eclampsia.

Tularemic Encephalitis.—Hartman describes a case of acute tularemia with diffuse encephalitis and coexisting tuberculosis of the kidney and epididymis. The brain lesions were readily seen as areas of yellow necrosis and hemorrhage throughout the base. Microscopically there was patchy necrosis with infiltration of round cells, wandering cells, and polymorphonuclear leukocytes.

Frequency of Anomalous Reticula in Right Atrium of Human Heart "Chiari Network."—Helwig defines a true "Chiari network" as an anomaly which is formed of strands and reticula which stretch from the thebesian and eustachian valves across the right auricle to insert either into the crista terminalis or the endocardium near the tubercle of Lower. Several explanations of this anomaly have been proposed to account for its development. Chiari thought that it was a remnant of the right venous valve of the septum spurium. Looser believed that it arose from a dislocation of the fibers from their normal points and took place as a result of irregularity in endocardial growth. Jordan, in reporting two cases, was inclined to the view that the network was formed from remnants of portions of the valves of the right horn of the sinus venosus. Since Chiari's publication, fifteen additional cases have been studied and added to the literature. From the small number of reported instances of this anomaly one might assume that these structures are quite rare, while the author's observations lead him to believe that the contrary is true. In a series of 460 necropsy examinations conducted at St. Luke's Hospital from Jan. 1, 1928, to July 1, 1931, a period of three and a half years, seven hearts showing this anomaly were seen, an incidence of 1.5 per cent.

American Journal of Public Health, New York

12: 1-126 (Jan.) 1932

Cost of Sanitary Survey of Streams. W. L. Stevenson, Harrisburg, Pa.—p. 1.
*Diphtheria Toxin-Antitoxin and Toxoid: A Comparison. W. H. Park and May C. Schroder, New York.—p. 7.
*Advantages of Toxoid in Diphtheria Prophylaxis. W. T. Harrison, Washington, D. C.—p. 17.
Experiences with Diphtheria Toxoid in Canada. J. G. Fitzgerald, R. D. Defries, D. T. Fraser, P. J. Moloney and N. E. McKinnon, Toronto, Canada.—p. 25.
Degree of Immunization from Injection of Diphtheria Toxoid: (a) of Different Strength Toxoids, (b) at Varying Intervals, (c) of Treated Toxoids. O. R. Povitzky, New York.—p. 29.
Preparation of Stabilized Schick Toxin. P. J. Moloney and Edith M. Taylor, Toronto, Canada.—p. 38.
What Can a Community Do When It Is Not Yet Ready to Establish a Mental Hygiene Clinic? H. G. Weiskotten, Syracuse.—p. 44.
Marketing Mass Education. H. N. Calver and B. Brown, New York.—p. 49.
Health Aims and Professional Services: Infancy, Preschool and School Ages: Medium City. W. W. Bauer, Racine, Wis.—p. 59.
Accuracy of Counting an Agar Plate. F. L. Schacht and A. H. Robertson, Albany, N. Y.—p. 80.

Diphtheria Toxin-Antitoxin and Toxoid.—Park and Schroder state that the immunizing effects of their best toxoid have been better than from the best properly standardized toxin-antitoxin. They have therefore recently adopted the toxoid (Ramon) for the children of preschool age in New York City but continue to use toxin-antitoxin for the school children and for such adults as, for instance, nurses, who require it. They may soon employ the toxoid entirely, especially if they are able to reduce the substances in it which cause pseudoreactions.

Advantages of Toxoid in Diphtheria Prophylaxis.—Harrison summarizes the advantages of diphtheria toxoid over toxin-antitoxin mixture as follows: 1. It is from 20 to 30 per cent more effective, even when only two doses are given. 2. It contains no serum or other animal protein likely to sensitize to a later therapeutic serum injection. 3. It is absolutely without local or general reaction in practically all children under 7 years of age. Reactions in older children and adults are only unpleasant, not dangerous. 4. It contains no free toxin. 5. It is more stable, retaining its effectiveness for a longer period, and is not affected by freezing.

American Journal of Surgery, New York

15: 1-218 (Jan.) 1932

*Tribromethanol-Amylenehydrate ("Avertin" Fluid): Report of Three Hundred and Fourteen Basal Anesthesias Administered to Two Hundred and Twenty-Five Patients. E. F. Goldschmidt and A. M. Hunt, New Haven, Conn.—p. 1.
Uretero-Intestinal Anastomosis: Simplification of Coffey Technic. H. D. Furniss, New York.—p. 12.
*Transplantation of Ureters to Rectosigmoid and Cystectomy for Exstrophy of Bladder: Seventy-Six Cases. W. Walters, Rochester, Minn.—p. 15.
Radical Electrosurgical Mastectomy: Report of Illustrative Case. S. H. Groff, Ojai, Calif.—p. 23.
*Lumbosacral Sympathetic Ganglionectomy. H. Ito, Kyoto, Japan, and G. Asami, Ehime, Japan.—p. 26.
Chronic Hypertrophic Vulvitis Complicating Pregnancy. P. Rucker, Richmond, Va.—p. 39.
Blood Transfusion: Its Importance in Practice of Obstetrics. E. C. Lyon, Jr., New York.—p. 42.
Prolapse of Rectum and Uterus in Same Patient. E. P. McDonald, Albany, N. Y.—p. 47.
Pyelographic Evidence of Horseshoe Kidney: Report of Case in Girl Thirteen Years of Age. S. J. Sinkoe, Atlanta, Ga.—p. 51.
Ureter Catheter Drainage in Ureterotomy. W. M. Kearns and S. M. Turkeltaub, Milwaukee.—p. 56.
Conjugal Infection of Bacillus Coli Associated with Gangrene of Testis. M. W. King, Cleveland.—p. 61.
Functional Position from Orthopedic Standpoint. G. Anopol, New York.—p. 63.
Incision for Exposure of Elbow Joint. W. C. Campbell, Memphis, Tenn.—p. 65.
New Bone Lengthening Apparatus for Femur. G. K. Coonse, Columbia, Mo.—p. 68.

Intra-Articular Stabilization of Recurring Dislocation of Shoulder: Technic of Suspension of Acromium by Autogenous Fascia Lata Suture. C. M. Gratz, Assisted by R. P. Robison, New York.—p. 71.
*Operative Cure of Hallux Valgus and Bunions. S. Kleinberg, New York.—p. 75.
Osteomyelitis of Vertebrae: Two Cases Simulating Perinephric Abscess. J. A. Lazarus, New York.—p. 82.
Method of Inserting Blood Transfusion Needles into Veins. J. M. Scannell, Jamaica, N. Y.—p. 88.
Spinal Anesthesia Records. R. C. Webb, Minneapolis.—p. 91.
Healing of Chronic Duodenal Ulcers. T. L. Bliss, Rochester, Minn. —p. 93.
Adenocarcinoma of Sigmoid with Metastasis to Eye. C. F. Dixon and W. L. Benedict, Rochester, Minn.—p. 99.
Traumatic Rupture of Stomach: Two Cases. C. R. Fancher and M. G. Barmore, Oakland, Calif.—p. 101.
Treatment of Certain Cases of Duodenal Ulcer by Jejunostomy, with Application of Some Newer Physiologic Principles and Use of Electric Feeding Pump. E. H. Mensing, Milwaukee.—p. 105.
Gastrocholecystic Fistula: Case. J. O. Rankin, Wheeling, W. Va.—p. 109.
*Acidosis Treatment of Inoperable Malignant Tumors. W. Meyer, New York.—p. 112.
Diagnosis of Ureteral Calculi and Problem of Their Conservative Management. A. M. Crance, Geneva, N. Y.—p. 120.
*An Electrosurgical Rongeur. G. E. Ward, Baltimore.—p. 130.
Clinical Management of Horseshoe Kidney. Part II. R. Gutierrez New York.—p. 132.

Tribromethanol-Amylenehydrate ("Avertin" Fluid).—Goldschmidt and Hunt present their experiences with 314 basal anesthesias with "avertin" administered to 225 patients. The drug was instilled by rectum as a 2.5 per cent solution in distilled water, usually in doses varying between 0.08 and 0.1 Gm. per kilogram of body weight, to patients of both sexes between the ages of 2 and 73 years, for operations requiring surgical anesthesia. Parenchymatous liver damage and extensive bilateral kidney disease are the only contraindications for the use of this anesthesia. It is concluded that, administered in sufficient doses, no less than 0.08 Gm. per kilogram of body weight, "avertin" fluid produces a good basal anesthesia. In only about 3.5 per cent of the cases was a satisfactory action not observed. In about 24 per cent of the cases full surgical anesthesia was obtained; in about 20 per cent the basal anesthesia was supplemented with local anesthesia (procaine); in the remaining cases ether, ethylene, oxygen, nitrous oxide, oxygen or a combination was employed at various phases of the operation. In all instances the necessary dose of the supplemental inhalation anesthetic, however, was only a fraction of the amount usually required for the operation performed. A temporary fall in the systolic blood pressure of about 19 mm. of mercury in men and 28 mm. in women occurred following the instillation. Studies with the cardiotachometer of Boas showed that the abrupt changes in heart rate produced by excitement at the beginning and the end of the anesthesia were markedly reduced or practically absent. The most striking of the advantages in the use of this basal anesthesia is the complete amnesia observed in all patients, they having no recollection whatever of the events following the instillation of the "avertin."

Transplantation of Ureters.—Walters reports the results obtained in transplantation of ureters to the rectosigmoid and removal of the exstrophied bladder in a group of seventy-six patients operated on at the Mayo Clinic. The method of transplantations was first used by C. H. Mayo in February, 1912; he applied Coffey's principle of submucous duct transplantation to the ureter. The operative procedures have been divided into three stages: (1) transplantation of the right ureter into the rectosigmoid, (2) two weeks later transplantation of the left ureter, and (3) ten days later removal of the exstrophied bladder. In none of the cases were ureteral catheters used in the transplantation. Three patients died in the hospital subsequent to operation. Twenty-seven patients have lived five years since the operation, and thirteen have lived ten years. Results were unsatisfactory in only three cases. In 50 per cent of the cases there was no evidence of renal infection. In 21 per cent there were short periods of mild renal infection; the interval between such periods in most cases was many months, sometimes years. The infection, too, was mild and apparently had little effect on the patient. The use of compounds such as iopax intravenously has made possible the study of renal function as well as of the outline of the renal pelvis and ureter in many of these cases. The use of this method and other methods of study of renal function leads to the belief that renal function is normal and that there is no dilatation of the pelvis, calices or ureters in cases in which the ureterosigmoidal transplantation is accurately carried out.

Lumbosacral Sympathetic Ganglionectomy.—Ito and Asami give a clinical account of twenty-seven cases of thrombo-angiitis obliterans together with a brief description of the technic of operation developed in their clinic in which the lower lumbar and upper sacral ganglions are removed with the intervening cord. A brief description of the animal experiments performed in their laboratory, showing the definite increase in the volume flow of blood through the homolateral limb, and facilitation of wound healing thereby, is given. In the treatment of the symptom groups of thrombo-angiitis obliterans, apparently permanent and complete cure is obtained by the lumbar and lumbosacral sympathicoganglionectomy in their earlier stage of intermittent claudication. With the development of gangrene and obliteration of the popliteal or tibial artery, on the other hand, the result of the operation is not satisfactory. Obviously, therefore, such patients should be operated on at the earliest possible stage of the disease. The authors present clinical evidences contradictory to the doctrine of sympathetic tonic innervation of the skeletal musculature.

Operative Cure of Hallux Valgus and Bunions.—Kleinberg believes that the main basic factors in the etiology of hallux valgus and bunions are the adduction of the metatarsal bone of the great toe and the obliquity of its tarsometatarsal joint. The conspicuous and obvious causes of discomfort and disability are the valgus of the great toe, bony overgrowth at the base of the great toe and the overlying bursa or bunion. The author's operation aims to correct all the pathologic changes without disturbing the function of the great toe joint or weight bearing surface of the head of the first metatarsal. The adduction of the first metatarsal bone is corrected by the removal of a double wedge from the tarsometatarsal joint, the mobilization of the metatarsal bone, and the manual approximation of the first and the second metatarsal. The overgrowth of bone on the head of the metatarsal and the bunion are excised through a separate incision. The correction of the valgus of the great toe is assured by securing to the metatarsal bone a tongue of strong tissue, consisting of bursal wall and capsule, which is attached to the base of the phalanx. Care is exercised not to remove or in any way disturb the articulating portion of the head of the metatarsal bone. This accomplishes two results: namely, the support of the forefoot is not altered and the mobility of the great toe is not diminished. By bringing the great toe into line with the inner border of the foot, the sesamoid bones are returned to their normal relation to the head of the metatarsal, and the dorsal and plantar tendons of the great toe are brought into a normal or nearly normal position, where they can function properly.

Acidosis Treatment of Inoperable Malignant Tumors.—Meyer states that in patients afflicted with technically inoperable cancer, with or without metastases, all factors known to produce acidosis of the blood, properly selected, combined and adapted to the case in hand should be put into operation as quickly and as vigorously as possible. The biologic acidosis treatment of inoperable malignant tumors must be worked out further by cooperative efforts of the members of the medical and affiliated professions. The author believes that those who are working along the lines of acidosis treatment of patients afflicted with inoperable malignant tumors are on the right track.

Electrosurgical Rongeur.—Ward has devised an efficient electrosurgical bone rongeur by attaching a binding post to the usual form of rongeur for the connection of the cable from the electrosurgical generator. With this rongeur, otherwise inoperable, malignant bone is removed in dead pieces without danger of metastasis.

Pemphigus: Recovery Following Long-Continued Colonic Irrigations and Arsenic by Mouth. J. F. Schamberg, Philadelphia.—p. 134.

Mycosis Fungoides.—Symmers is of the opinion that postmortem and histologic observations show that mycosis fungoides is the cutaneous expression of at least three different diseases of the lymph node system: Hodgkin's disease; a variety of round cell sarcoma arising from the connective tissue reticulum of lymph nodes or elsewhere, and lymphosarcoma, originating in the lymphoid cells of the lymph nodes or of other lymphoid structures—in short, that mycosis fungoides as an independent form of disease does not exist.

Sunburn Tanning.—Goodman reviews the factors of pigmentation of the normal skin and discusses the features of induction of pigmentation of the white man's skin by radiation from solar and artificial sources. The subject of sensitizing the skin to make it more amenable to the production of pigment through erythema-producing radiation is touched on, particularly as it affects cosmetic tanning, photogenic diseases and eruptions of the skin partially responding to solar radiation. This entire subject of the biology of pigment in relation to vital ultraviolet radiation is important in view of the wide use of emanators of this type of radiation and the equally wide use of medicines of the coal tar derivative group, since it appears that coal tar quotients by ingestion in some persons induce a sensitivity to ultraviolet radiation. Local responses to the topical application of coal tar products and to erythema-producing ultraviolet rays produce conflicting results as far as pigmentation is concerned. Such a combination is offered in the treatment for vitiligo and leukoderma, and a like combination is also offered as the solution of the etiology of perfume dermatitis. The author believes that the biologic reaction of the skin to sources of light must also be considered in cancer of exposed surfaces of the skin and in some industrial dermatoses.

Mouth Lesions from Artificial Dentures.—In routine examination of the mouths of forty-five consecutive adults wearing full plate dentures, Lain noted that 42 per cent had either stomatitis or glossitis. It was found that many of these cases were due to neglected oral hygiene, malocclusion or trauma caused by imperfect adaptation of the plates to the alveolar processes. In several cases, however, after all ordinary etiologic factors had been eliminated, it was concluded that the poisonous constituents of the dental plates were the offending agents. Analyses of the plates in two of these cases revealed porosity with free mercury sulphide and sulphur in one, and aluminum powder with a trace of zinc in the other. Macroscopic and microscopic examination of other offending plates indicated undercuring with porosity. Each of thirty consecutive adults examined, whose mouths contained two or more metals of different potentialities, registered from 1 to 40 degrees of galvanic current on the micro-ammeter. One case of a metallic upper plate with amalgam fillings below registered a dangerously high degree of current. A large percentage of the patients complained of symptoms, such as metallic taste, burning tongue and acute dental nerve sensations, or presented visible mucous lesions adjacent to or between metallic dentures, from which, after a process of elimination, it was concluded that the etiologic factors were galvanic discharges.

Neoarsphenamine Intoxication.—Ronchese reports a case of dermatitis with jaundice followed by a generalized melanoderma, respecting, as did the erythrodermia, the areas previously the site of a roseola, following the use of neoarsphenamine. He calls attention to the fact that the absence of erythrodermia and pigmentation in these areas, leading to a picture of a leukomelanoderma, should help to demonstrate the pathogenesis of the syphilitic leukoderma as due to a secondary hyperpigmentation of the skin surrounding the sites of a previous noticed or unnoticed syphiloderma.

Coccidioidal Dermatitis.—Zeisler describes an unusual case of widespread dermic infection with Coccidioides immitis. The patient presented a combination of nodular, crusted, granulomatous lesions resembling mycosis fungoides, with lichenoid papules simulating miliary lupus and pigmented, atrophic, annular scars. In the later stages, the papillomatous and verrucose character of the eruption gave rise to a close clinical resemblance to blastomycosis. The chronic nature of the dermic lesions and the absence of demonstrable subcutaneous, glandular, pulmonary or osseous lesions suggests the term, chronic coccidioidal dermatitis as an appropriate one for this type of case. The skin as the portal of entry of the infection, and the possibility of animals being carriers of the disease is suggested by the history of the case. The temporarily favorable results of treatment with alternating courses of colloidal copper and antimony and potassium tartrate, and roentgen therapy, locally, are recorded. The histologic changes produced by the growth of Coccidioides immitis in the tissues in the form of nodules surrounding the blood vessels suggests dissemination by the blood stream. A peculiar type of segmental endosporulation is described which has been observed only once before, by Rixford and Gilchrist. The gross and the histologic changes produced in experimentally infected guinea-pigs are described and the parallelism to human infection is noted.

Demodex Folliculorum.—Ayres and Anderson report seventeen cases of acne rosacea in which Demodex folliculorum was found in moderate to large numbers either in pus from superficial lesions or in dry follicular scales, whereas it was absent from the pus in thirteen consecutive cases of acne vulgaris. Following the use of a strong antiparasitic ointment and the daily use of soap and water in twelve of the cases, the acne rosacea was either improved or clinically cured in all instances. Accompanying the clinical disappearance of the lesions of acne rosacea, Demodex folliculorum was present in correspondingly fewer numbers, and in some cases there was a total disappearance of the organisms. On the basis of their observations the authors conclude that Demodex folliculorum is one of several possible causes of acne rosacea.

Kinking of Scalp Hair.—The report of Wise and Sulzberger deals with an anomaly of hair growth and hair color which apparently is unique in medical literature. The patient was a man, aged 21, who complained that his light brown, straight and exceptionally vigorous head of hair had begun to undergo a change about two years before he consulted the authors, with the result that the frontal, temporal and parietal portions of the scalp hair had become "wooly and kinky" and had changed from light brown to black. This curious change in physical character and color was progressive and rather rapidly advancing, in that an extension of the process took place while the man was under observation. The kinky hair was pigmented in shades varying from dark brown to black. The shafts were much thinner than those of the straight hairs, their diameters being from one-half to one-fourth narrower than those of the straight hairs. While the majority of these kinky hairs exhibited no structural changes deviating from the normal, a small proportion of the specimens presented little globular and roughly spindle-shaped swellings of the shafts, and not more than two or three of them affected an individual hair from end to end. These dilated areas showed no difference in cellular structure as compared with other parts of the shaft. Close to the distal ends of many of these hairs, the shaft was split in two or three segments.

Effect of Vitamin B Complex Depletion on Infant Mortality.—Maurer and Loh Seng Tsai report that an analysis of the mortality of infants who die the first year, in Illinois, shows that 44 per cent die under 1 week of age. The decrease in infant mortality from 1925 to 1928 of infants under 1 year of age was 1,488, while there was a decrease in the group who die under 1 week of only 213. The infant mortality of the offspring of mother rats receiving a diet which is adequate only for normal maintenance of a nonpregnant rat is high, 71 per cent, as compared with 8.5 per cent normal mothers. for animals under 3 days of age, an age equivalent to about 1 week in the human infant. A female rat which, during the period of gestation or while a nursling, has received only sufficient vitamin B complex for maintenance when not pregnant, suffers a dystocia. Analysis by Goldberger of the food consumption of wage earners shows that December, January, February, March, April, May and June are months in which the diet contains less than the optimal maintenance of vitamin B complex, and Illinois statistics show that there is a higher mortality of infants less than 1 month of age during these months than during August, September, October and November, the four months of lowest infant mortality. The months of lowest mortality of infants under 1 month of age are the months in which the mothers have had two or more months of a diet containing more vitamin B complex than maintenance just prior to the birth of the child. The ordinary minimal maintenance diet, from a standpoint of vitamin B complex, must be practically doubled during pregnancy in order that a strong, healthy offspring may be produced with the least damage to the mother.

Intra-Abdominal Hemorrhage from Ruptured Corpus Luteum Cysts.—Greeley emphasizes the fact that, in examining a female patient for an acute abdominal lesion, the possibility of intraperitoneal hemorrhage from a ruptured corpus luteum cyst must not be overlooked. Bleeding from a ruptured ectopic pregnancy, although quite common, usually gives a history of symptoms pointing toward a pregnancy, which are not usually found in ruptured corpus luteum cyst. A history of recent trauma to the lower part of the abdomen may be a highly significant factor in making the preoperative diagnosis of lower abdominal pain.

Rat-Bite Fever Transmitted by a Cat Bite.—Mock and Morrow state that rat-bite fever is probably overlooked more frequently than is realized. The mortal enemy of the rat, the house cat, may act as the medium for the transmission of the etiologic factor of rat-bite fever. There is a specific treatment —neoarsphenamine—in small divided doses. If in the course of employment an individual is bitten by a rat or a cat and later develops this peculiar type of relapsing fever, the case at once develops a medicolegal aspect. The question of employee's compensation for an accident must be met.

Restlessness in Infancy.—According to Carey, certain babies are born with, or develop shortly after birth, a hyperactive vagus associated with distention, due to spasm of certain areas of the gastro-intestinal canal producing pain and restlessness. Under proper placid surroundings and attendants, these babies are less likely to exhibit mental disorders in later life. Atropine in proper dosage acts as a specific in those cases of nervous origin. Roentgen therapy while tried in only a few cases, appears to be of decided value.

Management of Chronic Arterial Occlusions of Extremities.—De Takáts calls attention to the fact that the proper management of peripheral vascular diseases requires an exact determination of the type and extent of vascular disturbance. Spasms should be differentiated from organic obstructions. The early diagnosis of these cases is in the hands of the general practitioner. The surgeon usually sees the late stages in the form of irreparable damage. When the diagnosis and level of circulatory impairment are determined early, conservative treatment is often successful. The author briefly discusses various forms of treatment and the indications for surgical operations.

Pellagra.—Boggs and Padget present an analysis of 102 cases of pellagra. The analysis was undertaken primarily because of the relative increase of the disease in recent years, and also to see whether there was any foundation for the impression held by some that postalcoholic pellagra is different from the type. Thirty-one of the cases were of simple variety; forty were postalcoholic, and in thirty-one cases the disease arose as a complication of some other malady. The alcoholic variety of pellagra has become more than four times as common since the enactment of prohibition. The clinical features of the disease are pointed out, the diagnosis is discussed, and the observation is made that there exists no difference between the three types. Treatment is considered, with particular emphasis on the value of the liver diet, the dry treatment of the skin lesions, and the not too vigorous treatment of the stomatitis. Various theories as to the etiologic relationship between alcohol and pellagra are considered. Attention is called to the common occurrence of pellagra as a complication of debilitating disease.

Fetal Blood Studies. — Eastman reports a study of the carbon dioxide content, the carbon dioxide tension and the hydrogen ion concentration of fetal blood in normal and in asphyxiated babies. He observed that the carbon dioxide tension of fetal blood is normally higher than that of the maternal arm vein, the carbon dioxide diffusion gradient between fetus and mother being about 1.3 to 1. The elevated carbon dioxide tension of the mixed fetal blood supplying the brain of the fetus is difficult to reconcile with the apneic state of the fetus in utero and at present necessitates the assumption that the sensitivity of the fetal respiratory center, in respect to carbon dioxide at least, is definitely depressed. The primary blood chemical change in asphyxia neonatorum is a reduction in the oxygen content of the fetal blood to extremely low levels, the blood of the umbilical vein falling in fatal cases below one volume per cent. The carbon dioxide content of the blood in severe asphyxia neonatorum is slightly lowered as a result of the displacement of this gas from base by the large amounts of lactic acid present. The serum p_H of asphyxiated infants is reduced to the lower limits compatible with life, and in fatal cases may even fall below 7.00. The evidence indicates that the use of carbon dioxide as a resuscitating agent in asphyxia neonatorum is not only superfluous but may even be harmful in that it tends to aggravate an already existing acidosis. It is further suggested that other attempts at stimulation, such as slapping and tubbing, may also be deleterious. The author concludes that the chief therapeutic indication in asphyxia neonatorum is for oxygen (or air); the particular method by which the oxygen is administered seems of minor importance, so long as the air passages are clear and the pulmonary alveoli are supplied with adequate amounts of this gas.

- Maximum Dosage in Pollen Therapy. G. T. Brown, Washington, D. C. —p. 180.
- Urticaria Solaris. E. Weiss, Philadelphia.—p. 192.

Perennial Treatment of Seasonal Hay Fever.—Brown presents a modification of the specific treatment of pollen hay fever, consisting of a distribution of the injections at intervals of from three to four weeks throughout the year, instead of the usual preseasonal injections at intervals of five to seven days. One may institute the treatment at any period of the year, merely increasing dosage to maximum and then increasing the interval as tolerance permits. The actual number of visits to the office or clinic can be lessened from the usual twenty or more to twelve. There is little likelihood of an interruption of the treatment by illness or absence for other causes. It distributes the load of the physician's work in the clinic and in private practice throughout the year.

Asthmatic Attack in Chronic Allergic Asthma.—The bronchi were injected with iodized oil, and roentgenograms were made by Steinberg during the course of an asthmatic attack and during an interval between attacks. Postmortem material of patients dying from allergic asthma was correlated with the roentgenologic observations. On the basis of his study the author concludes that an asthmatic paroxysm is essentially due to bronchial occlusion by mucus as a result of a hypersecretory activity of the bronchial mucous glands. The degree and the duration of an attack are proportionate to the extent of mucous secretion and bronchial plugging. There is a reduction of functioning lung tissue due to a permanent bronchial occlusion. The extent of this reduction is proportionate to the duration of the disease and the severity and frequency of the individual attacks.

Congenital Protein Hypersensitiveness. — According to Ratner and Greenburgh, identical protein hypersensitiveness may exist in the human mother and her child. This hypersensitiveness is transferred by way of the placenta. The allergic antibodies responsible for this sensitization of the fetus in utero are shown to have the qualities of the Prausnitz-Küstner antibodies and are demonstrated in both the mother and her child. These antibodies further are shown to be identical with the anaphylactic antibodies, for anaphylactic shock and sensitization of the uterus were produced in guinea-pigs sensitized by human antibodies. Congenital protein hypersensitiveness is divided into two phases, active and passive, the existence of which places this type of sensitization on a basis as clearly defined as sensitization acquired through other portals, such as inhalation, ingestion or injection. Since sensitization of a human being can be acquired in utero before birth, it follows that allergy is not always dependent on chromosomal inheritance.

Studies of Blood and Urine Following Bromide Injections. — Hastings and his associates report experiments in which they demonstrated that red blood cells seem to have a stronger attraction for bromide ions than for chloride ions. The distribution ratios of bromide concentration between cells and serum are a uniform percentage greater than the chloride ratios. The presence of bromide lowers the chloride ratios even more. The kidneys seem to have a greater ability to excrete chloride than bromide. The excretion of chloride following a sodium chloride injection is practically equal to that following a similar injection of sodium bromide. The excretion of chloride and bromide is not altogether proportional to the concentration of these ions in the serum. After the injection of either sodium chloride or sodium bromide, the p_H remains rather constant but there are marked changes in the blood-water balance. The cells give up water, the water content of serum increases, the refractive index decreases, and the hematocrit reading falls. Most of these factors return toward normal and the hematocrit reading goes far above normal in the last few samples. Total carbon dioxide determinations were made only in the chloride injection experiments and showed a moderate drop in the value obtained after injection. The injection of either salt produces a moderate hyperpnea.

Antirachitic Activation of Milk.—Supplee and his associates present physical data indicating the character and the amount of radiant energy required for the antirachitic activation of milk and coordinate them with the biologic and clinical tests. The irradiation of the milk was carried out in thousand pound lots under commercial conditions which permitted a precise study of various factors. With a suitable quality and quantity of radiant energy applied under uniform conditions, the antirachitic and calcifying properties of milk can be regularly increased within a few seconds, as determined by biologic laboratory assays and clinical tests on infants. This high degree of activation is obtained without the development of adverse secondary reactions, which may occur after longer periods of exposure. The energy of the radiations from a suitable carbon lamp of the flaming arc type and a quartz mercury vapor lamp confers definite antirachitic and calcifying potency on milk treated according to a technic described by the authors. However, the spectral energy characteristics of the radiations from the carbon arcs are readily subject to control, as to both the quality and the quantity of the energy. Milk irradiated under controlled conditions described by the authors and subsequently dried by the Just process was found to protect even Negro infants from rickets during the winter months. Such milk manifested definite curative value in a number of cases, as shown by the marked healing in roentgenograms.

Normal Sensitivity of Cardio-Inhibitory Center.—Miles recorded continuous electrocardiograms taken with capacity in series for young men while reclining in a steamer chair, while chinning a bar directly above the chair, and during relaxation following this exertion. The transitions from quiet to work, and then to recuperation, were very prompt. The man, in chinning the bar, lifted the body weight a vertical distance of 2 feet, held it up for seven seconds, and then promptly relaxed in the chair. There was a slight general increase (3 per cent) in heart rate in anticipation of the exertion, but the exertion itself produced in the first four seconds an added increase of 25 per cent, and in the next four seconds 5 per cent. The heart rate remained at the exertion level during the first four seconds of recuperation. Then the rate lengthened so promptly as to reach the preliminary level in from twelve to sixteen seconds after the work had been finished. The group of young men showed less variability in heart rate during exertion than under conditions of quiet or recuperation. The author suggests two types of cardio-inhibitory adjustment: regular and oscillatory; each of these may be further divided into prompt, average speed, and slow.

Effects on Pneumococci of Sodium Dehydrocholate.—Ziegler reports that pneumococci of type I, grown on artificial mediums, were not dissolved by sodium dehydrocholate but were killed or rendered avirulent so that they would not grow on artificial mediums or produce infection. Sodium dehydrocholate has an antipneumococcus action in the animal body. A mixture of sodium dehydrocholate and of pneumococci, when injected into rabbits, produces a degree of immunity to pneumococcus infection. Sodium dehydrocholate does not produce local tissue injury as does sodium taurocholate and glycocholate.

Detoxification of Cocaine, Picrotoxin and Strychnine by Sodium Amytal.—According to Swanson, protection is afforded by sodium amytal against intoxication of cocaine, picrotoxin and strychnine. The intravenous and oral administration of sodium amytal in the order named offers the more effective protection for all three poisons. Sodium amytal is an anticonvulsant as well as a detoxifying agent for the three poisons.

Control of Pain Following Tonsillectomy. A. F. Laszlo, New York.—p. 66

Meningitis of Otitic Origin.—According to Dwyer, the fact that in otitic meningitis so many kinds of treatment have been suggested and that the problem has been approached from so many points of view, and especially that the death rate is so high, simply indicates that the treatment is still *sub judice*. Practically every method of treatment has been used. The problem has been approached from two main avenues. One is based on surgery and drainage, such as repeated lumbar punctures, drainage of the cisterna, and so on. The second has been the injection of antiserums and drugs into the spinal fluid. The third has been a combination of the two. The author has tried all three, and no real progress can be reported in any series of cases. Eight of the patients in his series got well under different methods. The same methods failed in the vast majority of cases. With the brilliant results obtained in the treatment of the epidemic form with a specific antiserum, it seems to the author that the greatest hope will be the development of antiserums.

Prophylaxis and Treatment of Meningitis.—Kolmer summarizes the results of his clinical and laboratory investigations on the prophylaxis and treatment of septic meningitis in the form of clinical recommendations as follows: 1. Vaccination: In selected cases of chronic sinusitis and otitis and especially ethmoiditis, when extensive operative procedures are required, with the possibility of secondary meningitis, it is recommended that careful bacteriologic examination be made with the preparation of autogenous vaccines containing approximately one billion micro-organisms per cubic centimeter. When time permits, at least six to eight doses should be given at intervals of four to seven days. For adults the first dose may be 0.2 cc. by subcutaneous injection and subsequent doses gradually increased until 1 cc. is being given. Intracutaneous injections of 0.2 cc. per dose (not increased) may result in better immunization. Operation may be done about one week after the last dose. 2. Serum prophylaxis: If pneumococci are found it is advisable to determine the type, which requires an additional eighteen to twenty-four hours, because this information is of value from the standpoint of dosage of serum and prognosis. In infections of adults with type I pneumococcus, 10 cc. of Felton's concentrated antipneumococcus serum may be injected intramuscularly just before or immediately after operation; a second dose may be given the following day, and a third dose four days later. In infections with pneumococcus type II and group IV, the same dosage, or 15 cc., should be used; in infections with type III pneumococcus, a dosage of 20 cc. should be employed. The same doses may be given to children over 10 years of age; half doses to younger children. In infections with the streptococcus, a therapeutic syringeful of concentrated polyvalent antistreptococcus serum may be given just before or immediately after operation, repeated the following day and again four days later (in unusually severe infections), or an intramuscular injection may be given for the first dose, followed by one or two doses at the same intervals. Children under 10 years may receive about one half of these amounts. 3. Treatment of early meningitis: On the development of signs and symptoms of meningitis, spinal puncture may be conducted for the slow removal of about 3 to 5 cc. of fluid. If examination discloses the presence of a localized "meningismus" or meningitis there should be a complete exenteration of the cells in cases of acute mastoiditis and radical operation in cases of chronic suppurative otitis media. If the portal of infection has been the labyrinth, thorough drainage should be established through the labyrinth and in all cases it is advisable to incise the dura at the site of operation. In sinus cases, careful thought should be given to reoperation for the purpose of affording the best possible drainage. The intake of fluids may be increased and spinal drainage conducted every six to eight hours. Intracarotid and subthecal medication may be omitted. 4. Treatment of diffuse meningitis: If the foregoing measures fail to check the infection or if the clinical and spinal fluid examinations disclose a spreading type of meningitis, more radical measures should be decided on without delay because there appears to be little or no hope of success in the treatment of advanced cases.

Position in Tonsillectomy.—Ziegelman states that aspiration is apparently one of the causes of abscess of the lung following tonsillectomy. The position of the patient during operation is probably a factor in the formation of aspiration. The so-called modified Rose position from the standpoint of mechanics overcomes the tendency to aspiration. This position is ideal for orientation of the operative field. It is the logical position for the control of hemorrhage in the prevalent and always difficult area (the lingual area) and it is the position of choice for the prevention of surgical shock.

Michigan's Department of Health. C. C. Slemons, Lansing.—*p. 46.*

Surgical Lesions of Large Bowel.—According to Rankin, consideration of surgical diseases of the large bowel revolves around malignant tumors, for more than two thirds of all lesions requiring extirpation are carcinomatous. A review of colonic and rectal surgery at the Mayo Clinic for a year reveals the fact that 68 per cent of the total number of operations on the colon or rectum that were required for major lesions were for carcinoma. In addition, however, such lesions as tuberculosis, diverticulitis, polyposis, Hirschsprung's disease, fecal fistula, and an occasional bizarre condition, such as intussusception or another benign lesion, required attention. The author calls attention particularly to three problems directly associated with malignant disease of the colon: (1) the relationship of polypi to the development of carcinoma, (2) improved diagnostic methods, and (3) the choice of operation and its mortality.

Treatment of Hydronephrosis.—Ormond believes that, in selected cases of hydronephrosis, plastic operations on the ureteropelvic junction are indicated. A pyelogram of the supposedly uninvolved kidney should be a part of the diagnostic procedure in every case of hydronephrosis. The factors to be considered in deciding between a plastic operation and nephrectomy are (1) the condition of the opposite kidney, (2) the functioning power of the affected kidney and the cause of the hydronephrosis, (3) the age of the patient, and (4) his financial status. Following a plastic operation, all patients should have the benefit of ureteral dilation and pelvic lavage.

Paraplegia and Nontuberculous Kyphoscoliosis.—According to Viets and Clifford, pressure paraplegia may occur as the direct result of angulation of the spinal cord secondary to severe kyphoscoliosis. The paraplegia usually appears after many years of scoliosis, without predisposing trauma. The paralysis, spastic in type, is associated with sensory changes below the point of compression, sphincter weakness and, rarely, pain. Block in the pathway of *the spinal fluid* may be demonstrated by pressure studies and by the injection of iodized poppy-seed oil 40 per cent. Some patients are relieved or even cured by hyperextension of the spine, but most patients require surgical decompression of the impinged spinal cord at the point of maximum angulation of the spine. *The* prognosis, with appropriate treatment, is often good and sometimes excellent.

Intravenous Pyelography During Pregnancy.—Prather and his associates have found that intravenous pyelography is useful during pregnancy in which a kidney diagnosis is desirable but in which cystoscopic examination is not indicated. Satisfactory films can be obtained in at least 91 per cent. The majority of best plates are obtained from five to fifteen minutes after the injection has been completed. The authors did not observe any obstetric complications that could be related to the examination. With the roentgenographic technic described by them, there seems to be no danger to the fetus either from the solution injected or from the roentgen rays.

Physiology of Gallbladder.—According to Levyn, the three significant functions of the gallbladder are the evacuation of its contents brought about by contraction of its musculature, concentration of its contents through the absorption of water, and the secretion of mucus. Some workers have shown that dyes placed in the lumen of the gallbladder find their way into the lymphatics and that there is a probability that cholesterol is also absorbed from the bile. It is uncertain, however, whether this is a normal function or this phenomenon indicates very early gallbladder disease. The earliest pathologic changes in the gallbladder undoubtedly are directly related to disturbance of function, and cholecystography is of inestimable value as a functional test. If stasis of the bile occurs with no undue increase of cholesterol, active concentration may induce precipitation of other constituents of the bile with the formation of other types of stones.

Precipitation Test for Syphilis.—Eller and Rein describe experiments in which they noted that the microscopic slide precipitation test with spinal fluids was more sensitive than the Wassermann reaction, modified Kahn test, colloidal gold reaction and albumin-globulin ratios. This test gave results which agreed more frequently with the clinical condition of the patients than those of the other spinal fluid tests used in this series. The test is simple in detail and the results magnified by the microscope are read accurately with ease.

Pulmonary Disease as Result of Infection of Nasal Accessory Sinus.—Manges states that cold in the head, followed by laryngitis, bronchitis, asthma, or maybe bronchopneumonia, either is infectious, in the first place, or soon becomes so. The course of this process is not well defined; its progress is not associated with severe reactions or excessive prostration unless bronchopneumonia develops, so that the condition is not taken seriously until asthma incapacitates the patient or cough becomes so severe as to demand attention. Asthma becomes a custom with the patient, and cough develops into chronic bronchitis, the forerunner of bronchiectasis. The underlying cause or source of infection in many cases lies most commonly in the maxillary antrums and ethmoids, but any or all of the accessory sinuses may be at fault.

Unstable Colon.—According to Kantor, the unstable colon is one of the most common and disabling diseases encountered in practice. A certain amount of variability of colonic function is normal. Among the important causes of colonic instability are disorders of the nervous system, inappropriate diet, and vicious bowel habits. Nervous causes of colonic instability probably include disturbances of the psychic sphere as well as imbalance of the autonomic system. The chief dietary factors in colonic instability are rough foods, cold foods, and foods causing allergic manifestations. The chief causes of vicious bowel habits are popular misinformation, the ease of self-medication, and the relative unattractiveness of securing and following a conservative plan of treatment. The chief manifestations of colonic instability are constipation, diarrhea, "belly consciousness" and pain. Pain due to colonic instability is often mistaken for evidence of organic abdominal disease. Appendectomy has been frequently performed in cases of unstable colon. The diagnosis of colonic instability is readily made by roentgen examination. Especially useful is the nine-hour observation. Reassurance, relaxation and reeducation are the keynotes of successful restoration of normal bowel function.

Mortality in Appendicitis.—According to Cottle, acute appendicitis operated on before the stage of abscess and generalized peritonitis are practically devoid of mortality. After forty-eight hours from onset the mortality rises. The author believes that every abdominal pain should be considered appendicitis until proved to be due to another pathologic condition. A rising pulse generally means peritonitis in cases that begin with abdominal pain. The decision for or against operation should be made after a brief (two or three hour) period of intensive study of the case. Operation should be offered as soon as the diagnosis is made and usually when acute appendicitis cannot be conclusively ruled out. The Ochsner treatment should not be used in appendicitis. It is advocated only for cases of generalized peritonitis—pulse over 130 and a silent distended abdomen. The pelvic appendix with its atypical onset and course must be remembered, bladder and rectal symptoms associated with abdominal pain given careful consideration, and the rectal examination not forgotten.

Significance of Schilling Differential Blood Count.—McGee emphasizes the fact that much can be learned relative to diagnosis, prognosis and treatment by use of the Schilling hemogram. The changes in the granulocytes often precede physical signs, symptoms, fever and total cell count changes. Repeated hemograms carefully done reduce the need of total white counts, which are often insignificant in comparison to the differential study. The hemogram is sort of a kaleidoscopic view of the infection in the blood. An outstanding blood picture should not be ignored because of the absence of clinical symptoms. The author believes that the Schilling hemogram should replace the Ehrlich differential count. The use of the Giemsa stain shows the granulocytes, lymphocytes and monocytes more clearly than Wright's stain, and should supplant the latter except in emergencies.

Rôle of Lactic Acid in Living Organism.—Himwich calls attention to the fact that the reactions attendant on the formation and removal of lactic acid are of utmost significance in the economy of the body. During rest and exercise they are involved in processes that deliver energy for the work of life. Though the splitting of phosphocreatine furnishes the energy for the contraction of muscle, exercise cannot continue long without the formation of lactic acid, for the energy thus made available is the direct cause of the resynthesis of adenosintriphosphate and therefore indirectly that of phosphocreatine. Liver as well as muscle is involved in the processes of recovery as lactic acid is reconverted to glycogen. The reversible reactions between glycogen, dextrose and lactic acid not only are important for skeletal muscle, but also are concerned in the work of cardiac and smooth muscle, the brain and perhaps in that of peripheral nerve conduction. At present there is no proved connection between lactic acid formation and glandular secretion. The exchanges of dextrose and lactic acid in the blood of liver, heart, brain and skeletal muscle are indicated in a diagram which shows that muscle is the chief source of the blood lactic acid while the liver is the chief source of dextrose. Heart and brain remove both dextrose and lactic acid from the blood. The action of the liver in removing lactic acid from the blood and supplying it with dextrose is an etiologic factor in the maintenance of the hyperglycemia of diabetes. When this mechanism is interfered with, as a result of severe injury to the liver, lactic acid may accumulate. Since oxidations are necessary for the resynthesis of glycogen, oxygen lack is always followed by an increased concentration of lactic acid in the body. Such a condition occurs most frequently in exercise. It is also found in patients, especially those with cardiorespiratory disease or anemia.

Cardiac Fallacy in Acute Rheumatism.—Llewellyn believes that the underlying morbid process in so-called acute rheumatism and chorea is one of endocrine autonomic imbalance involving especially the sympathetic divisions with their correlated endocrine glands, the thyroid and suprarenals (sympathetic) and parathyroids (parasympathetic). The morbid process or state of imbalance that determines what is termed acute "rheumatism" or "chorea" is a functional disorder. The same does not cause organic cardiac lesions in the majority of cases but only disturbances of cardiac rhythm which are mostly transitory in duration. The transitory cardiac arrhythmias, i. e., all states of dissociated rhythm, from "missed beats" to "incomplete heart block," are an integral part of the clinical syndromes termed acute rheumatism or chorea. They are the outcome of a transient phase of thyroidal or (as the author believes) of thyrosuprarenal toxicosis affecting the cardioregulatory or vasomotor system. This toxicosis—if prolonged, as in recurring attacks of so-called acute rheumatism or chorea or relapsing carditis—leads to endocarditis, myocarditis and terminal myocardial degeneration. But only in a minority do such organic cardiac lesions ensue. If the state of hyperthyroidism obtaining in so-called acute rheumatism or chorea evolves into or is preceded by exophthalmic goiter, it accentuates the tendency to organic cardiac lesions. The primary indication in therapy is to prevent, correct or control the initial tendency to endocrine-autonomic imbalance.

Treatment of Dysmenorrhea by Exercise.—According to Clow, the patient's history generally serves as an explanation of the cause of her dysmenorrhea. It is usually found that the age of its onset, most commonly 16 to 19, corresponds with some change in the daily routine, involving more restricted time for exercise and increased hours of work, owing to study for an examination, or entry to an office, shop or factory. With the first indication of menstrual trouble the inclination is to reduce the exercise still further, and, if possible, to lie down during the time of malaise. The author therefore explains that, to prevent or cure the pain, the circulation of the blood must be stimulated by muscular exertion. If there is not time or opportunity for sufficient exercise in the open air, it should be supplemented by exercise done at home. The author has selected a few movements as being specially effective for dysmenorrhea and has had them printed on a single sheet, which she gives to the patient and tells her to do them for a quarter of an hour daily for a few days before onset of the period, and on no account to fail to do them on the first and second days of the period. They should be done with enough vigor to promote a sensation of heat or a gentle sweat. With few exceptions this practice prevents the onset of the disability, and if the pain has already begun it is usually dispelled, or at least relieved, as soon as the feeling of warmth is experienced. Some, however, especially patients over 30, have to repeat the exercises two or three times on the first day in order to keep themselves free from pain. After continuing the treatment for six to twelve months, many are able to leave it off altogether, provided they are not engaged in sedentary occupations.

Bone Graft and Fusion Operations for Spine.—During the last few years, Malkin has had to consider carefully what is the best method of fusing the spine. After a trial of other methods he came to the conclusion that, from a practical point of view, the method of the double graft in the vertebral grooves was the soundest, the simplest and the most generally applicable. During the last twelve months he has used it in eight cases of varying type. While it is yet too early to speak of the final results, in all cases he has found the method (sometimes slightly varied) uniformly satisfactory.

Lichen Urticatus.—Chalke states that lichen urticatus frequently bears a striking resemblance to smallpox in the distribution of its lesions. The papules often prefer the limbs to the trunk, and the extensor surfaces to the flexor. The face receives little rash in the majority of cases. The lesions themselves differ markedly from those of smallpox, and this disease may be eliminated by careful examination.

Thallium Acetate in Treatment of Ringworm of Scalp.—Ingram believes that there is no serious evidence against the use of thallium acetate in the treatment of small-spore ringworm of the scalp if the drug is properly administered. Though toxic symptoms may occasionally be encountered, they are seldom severe and the patient invariably recovers completely. There is no evidence whatever to suggest that thallium acetate affects the growth or development of the child, or effects any permanent damage to any organ. The author describes a simple method of procedure, which, it is suggested, is perfectly safe and brings the practice within the scope of the general practitioner.

Low Visceral Tone.—Carmalt-Jones describes a series of cases in which physical and emotional weakness were found, with low blood pressure, visceroptosis, and a characteristic state of the tongue; a case more closely investigated showed low metabolism in every direction. The patients were women who had been subject to long-continued anxiety, and the condition is ascribed to functional insufficiency of the suprarenals.

Tonsillectomy in Childhood.—Keen studied the case records of 9,344 children who underwent tonsillectomy at a school clinic and analyzed all the chief medical and surgical complications, excluding hemorrhage. He observed that many illnesses which appear to be complications are really intercurrent infections which arise independently during the period of convalescence or already existed in a prodromal stage at the time of operation. This applies particularly to pulmonary complications, of which there were twenty-three in this series, eight of which are described in detail. In the "guillotine" method of tonsillectomy the anesthetic is short and the operation is rapidly carried out with the head of the patient in the extended position. Therefore, it is argued, the two important factors in the etiology of pulmonary complications, viz., ether irritation of the bronchial mucous membrane and inhalation of blood or septic material, can for practical purposes be excluded. Toxemia is a direct complication and results from an extension of the bacterial infection of the operation wounds. When the body defenses break down completely, generalized sepsis or septicemia may result. Five cases of postoperative septicemia, with one death, are described. Acute specific fevers sometimes complicate the convalescence and can generally be explained as intercurrent infections not directly connected with the operation. Diphtheria is particularly serious. Three cases are described, in all of which the diphtheritic infection was laryngeal and in two of which the patient died. In this series there were eighteen cases of scarlatiniform rashes after operation and five cases in which a diagnosis of scarlet fever was made elsewhere. Septic rashes of a scarlatiniform type after tonsillectomy are not very uncommon and they usually appear on the second or third day after operation. The diagnosis of scarlet fever is never justified under these circumstances. Acute otitis media is a definite complication of the operation. There were sixty cases in the author's series or 0.6 per cent. The prevention and treatment of earache after tonsillectomy is discussed. There were six cases of postoperative mastoid abscess and intracranial infection. These are described in detail and the pathology of fulminating meningitis following acute otitis media is considered. Lastly, a case of glottic spasm requiring laryngotomy, and a case of subcutaneous emphysema complicating the tonsil and adenoid operation, are described. The origin and mechanism of subcutaneous emphysema are described, with a consideration of the literature on the subject.

Coronary Circulation in Isolated Perfused Heart.—Rössler and Pascual analyzed the coronary circulation in the isolated perfused heart by means of the hot wire anemometer and discuss the chief peculiarities of this circulation. A convenient method for optical registration of the heart beat and a new method of heart perfusion are described. The statement of Hochrein and his co-workers that the coronary flow in a perfused artery is maximal during systole is not supported by the authors' experiments. The inflow is diminished by the contraction of the heart in proportion to its strength. Certain peculiarities of the coronary circulation, such as regurgitation and the overshoot, are described and analyzed. Examples are given of the action of various drugs, and it is shown how the vasomotor effect of a drug may be masked, accentuated or reversed by the action which the drug may simultaneously exercise on the heart beat.

Course of Vasoconstrictor Nerves to Periphery.—Gilding describes a method for following the distribution of the sympathetic nerves (and incidentally the motor and sensory nerves) to the tissues. The sympathetic nerves follow the motor or sensory nerves to the periphery, branching from them in the vicinity of the minute blood vessels innervated. The periarterial nerve plexus does not conduct impulses to the periphery. Stimulation of the stellate ganglion causes vasoconstriction in the skin, mucous membranes, muscles, bone, bone marrow, meninges, choroid plexus and thyroid.

Congenital Defects of Eye.—Mann states that whoever studies cases of developmental defect of the eye will be struck by the frequency with which they resemble in many ways the results of acquired disease. Conversely, many acquired conditions come to reproduce with varying accuracy the possible results of developmental aberrance. The chief interest of the subject lies in the disentangling of the appearances so as to arrive at a knowledge of the past causative agents. In most cases the problem is not an urgent one, since the more dramatic of the acquired diseases usually present no resemblance to congenital defects. Their remote results, however, may come to suggest strongly certain developmental anomalies. As good an example as any is seen in the fact that pathologic pigment on the lens capsule from past inflammatory synechiae tends after the lapse of years to assume a stellate form indistinguishable in appearance—though often not in position—from the congenital star-shaped pigment cells of minimal persistent pupillary membrane. Thus, a past attack of iritis may be misinterpreted and its possible present bearing on the case overlooked. An even more common dilemma—though likely to puzzle only the relatively inexperienced—is that of the diagnosis of medullated retinal nerve fibers from exudate due to inflammatory or vascular disturbance, especially should they occur in a patient with renal or cardiovascular disease. In dealing with this question of differential diagnosis it appears advisable to consider the commonest problems in the first place from their anatomic position. On this basis they can be divided into those involving the anterior parts of the eye and therefore visible by focal illumination, and those involving the fundus and visible only ophthalmoscopically. In some cases both situations present defects, the diagnosis thereby being rendered considerably easier, as when the presence of a doubtful pupillary membrane is made more certain by the presence of a coloboma of the disk in the same eye.

Diagnosis and Treatment of Pineal Tumors.—Harris and Cairns report the case of a youth, aged 20, with a history of four petit mal fits in four years, who complained of occasional giddiness on rising in the mornings and five months later began to have violent occipital headache. Papilledema developed rapidly, and localizing signs which were inconspicuous suggested a lesion of the posterior fossa or of the pineal gland. Cerebellar decompression was done seven months after the onset of symptoms without any tumor being found. There was rapid subsidence of papilledema with preservation of good vision, but signs of disturbance of the superior corpora quadrigemina at once began to appear. He remained well for five months but then had another attack of hydrocephalus and signs of pressure on the inferior corpora quadrigemina. At operation an apparently circumscribed pineal tumor was removed, but only after division of the right internal occipital vein near its point of entry into the vein of Galen. After operation there was on the left side hemiplegia and sensory loss which gradually recovered, and left homonymous hemianopia which remained complete. There was relief from headache and from deafness, but great unsteadiness in walking and disturbance of vision, although visual acuity was only moderately impaired. Nine months after the tumor had been removed, signs of recurrence became manifest. Under roentgen treatment there was rapid improvement, which was being maintained when the patient was last seen thirteen months after the second operation; that is, two years and seven months after the onset of symptoms.

Early Diagnosis of Whooping Cough.—Gardner and Leslie describe the bacteriologic method of diagnosis of whooping cough and report the results of more than 100 tests of suspected persons. These show that in the early stages of the disease at least three out of four cases can be detected by a single examination. The fourth eludes detection only because of human fallibility. The authors give reasons for the final acceptance of Hemophilus pertussis as the cause of whooping cough and emphasize the desirability of using antigenically efficient cultures in the manufacture of vaccines.

Treatment of Lobar Pneumonia by Artificial Pneumothorax.—According to Coghlan, the induction of artificial pneumothorax on the affected side in acute lobar pneumonia has the advantage that it (1) separates the inflamed pleural surfaces, relieves pain and allows of easy respiration, (2) puts the inflamed lung at rest, and (3) limits the flow of blood through the pneumonic lung, thereby diminishing anoxemia and interfering with the passage of toxins into the general circulation. From the experience gained in six cases, he draws certain conclusions as to the therapeutic results obtainable, and also as to the technic to be adopted to get the best results. The first and most obvious clinical result was that the induction of artificial pneumothorax initiated a series of events almost indistinguishable from the crisis which normally occurs in this disease. The second conclusion is that this control of the pneumonic process is at first only temporary, persisting merely as long as air remains in the pleural cavity. Since the absorptive capacity of the pleura in this disease is abnormally high—a factor which had not been suspected at the beginning of the investigations—the time taken to absorb the air is a matter of hours only, after which the pneumonic process becomes reestablished at its original level. By adequate refills, however, this return of the disease can be forestalled, and when the artificial pneumothorax control has been maintained for a sufficient length of time (forty-eight hours appears to be approximately correct) the pathologic process is definitely brought to an end, the air can be absorbed without any tendency to relapse, and convalescence proceeds normally. Resolution in the successful cases occurred more rapidly than usual, probably because, as the time of the disease was shortened, there was less damage done to the lungs and less exudate formed in the alveoli than if the pneumonia had been allowed to run its full course to a natural crisis. A striking feature of all the cases was the rapidity of the onset of the artificial crisis; profuse perspiration set in almost as the pneumothorax needle was withdrawn, and cyanosis and dyspnea were relieved in about fifteen to thirty minutes at most, causing corresponding subjective improvement. The fall of temperature was well established in from two to three hours, and the patient lost that appearance of acute distress characteristic of pneumonia. The following routine is proposed by the author for average cases: 1. Preliminary medication one hour before induction with one-fourth grain (0.016 Gm.) of morphine. 2. Thorough local anesthesia with procaine hydrochloride down to and including the parietal pleura. 3. Very thorough asepsis during induction. 4. A preliminary fill of from 400 to 600 cc. of air, run in very slowly during the negative phase of the pressure swing cycle, and with the needle clipped off during the high positive phases. 5. A second fill twelve hours later of from 300 to 500 cc. of air. 6. If the pneumonic process is not completely controlled, a third fill of from 100 to 150 cc. of air, which may be given in another twelve to eighteen hours. 7. Simultaneous exhibition of a suitable diaphoretic and of Felton's serum in appropriate cases at the discretion of the operator. Owing to the profuse perspiration, the comfort of the patient is much enhanced by warm sponging as needed and nursing between blankets. In cases in which it is deemed inadvisable to provoke defervescence by crisis, and a gradual fall by lysis is aimed at, three fills of from 100 to 150 cc. at intervals of six hours might be given and further treatment judged by results. No special points with regard to after-treatment were noted. Two patients were given blow-bottles with the idea of promoting reexpansion of the lung and absorption of any residual air, but this did not seem to be really necessary or to be of any particular advantage.

*Relapsing Fever: Case in an Infant Aged Eight Days. Annie V. Scott.—p. 782.

Scleroma.—Garber reports an early case of scleroma. So far as he is aware, this is the first time the disease has been recorded in China. A review of the literature was made and showed among recent developments the establishment of the value of the complement fixation reaction in recognizing antibodies of the Frisch bacillus. The thionin stain is recommended as a useful stain for studying some aspects of the histology of scleroma. In agreement with the majority of writers the author finds that the "hyaline cells" are derived from plasma cells. His evidence for the origin of Mikulicz cells from connective tissue cells supports the views of the majority of others and disagrees with views held by some more recent writers. Transition forms between plasma cells and connective tissue cells have been observed. The perivascular formation of plasma cells in scleroma is dependent on the presence of mother cells closely associated with the blood vessel walls. The mother cells are not of endothelial origin.

Coccidioidal Endophthalmitis.—The first case of coccidioidal granuloma in China is described by Chou and Reiss in a girl aged 6 months. A metastatic endophthalmitis of the left eye from the primary lesion on the side of the thigh, followed by atrophy of the eyeball was observed. Cystlike double contoured bodies were found in all the lesions, and most of these bodies contained from fifteen to twenty endospores. Inoculations of pus into the rabbit, guinea-pig, and rat resulted in the death of these animals in about ten days. A typical lesion resulted from the intradermal injection of the culture in the arm of the patient and revealed the original organisms. All the lesions, including the eye condition, subsided rapidly in about one month's time after hypodermic injections of emetine hydrochloride.

Relapsing Fever.—Scott reports a case of relapsing fever, developing in an infant 8 days of age. The mother was in her initial attack of relapsing fever during labor, the first symptoms having developed two days prior to delivery. The infant probably received the infection through the umbilical blood during delivery or by transmission from the mother after birth.

Eosinophilia in Malignant Tumors.—Chiray and Baudouin review the diseases in which eosinophilia is often observed. There is a slight and transitory eosinophilia during convalescence in infectious diseases, erysipelas, chickenpox, malaria, pneumonia, diphtheria and acute articular rheumatism. In septicemias the eosinophils are diminished during the active stage; their reappearance in all cases except those of endocarditis lenta is of favorable prognostic import. Eosinophilia is constantly present during the convalescent period of scarlet fever. From time to time an eosinophilia, possibly due to epiploitis or intestinal parasitism, is present in chronic appendicitis. Eosinophilia is noted at the end of acute attacks of tuberculosis, in the course of Addison's disease, in certain ovarian disorders and as a result of accidental or professional intoxication (hydrogen sulphide, arsphenamine, camphor, copper sulphate, benzene); in vesicular dermatoses, in foliaceous and vegetative pemphigus and in suppurations such as anthrax or phlegmons; also in anaphylactic diseases of the respiratory tract, such as asthma and hay fever. But eosinophilia does not seem to exist in attacks due to anaphylaxis of the digestive tract (urticaria, Quincke's edema, migraine) or in experimental hemoclastic crises. Only slight eosinophilia is present in skin diseases such as strophulus, eczema, herpes, psoriasis, tuberculous exanthems, lupus, erythema multiforme, sporotrichosis, mycosis and burns. Eosinophilia is important in the diagnosis of intestinal parasitism, particularly helminthiasis. It has been noted in myelogenous leukemia, in cardiac patients with asystole, in osteomalacia, and also during the course of pleural extravasations of indeterminate nature. The authors find that there is a leukocytosis and an eosinophilia in cancers, also, no matter where localized. Eosinophilia in neoplasms is only a secondary factor in the semeiology. They describe at great length a case of a febrile form of cancer of the pancreas, extending to the liver; the diagnosis was verified at operation. During the study the leukocytes went up from 7,200 to 28,000; the eosinophils increased from 19 to 41 and then to 70 and 80 per cent; the rest of the white cells were composed of lymphocytes and polymorphonuclear neutrophils, which descended from 46 to 28 and then 18 per cent. There was no anemia. The authors conclude that hyperleukocytosis in cancer is not a rare anomaly; that the leukocytosis in cancer is not neutrophilic but eosinophilic. Clinical and histologic examinations proved that the eosinophilia in the case described was directly or indirectly related to the cancer of the pancreas, to the secondary localization in the liver, or to the secondary abscess formation in the liver.

*Removal of Cervical Lymph Nodes. J. Heitz, E. Martin and P. Colson. —p. 655.
*Early Intervention in Knee Sprain. R. Leriche.—p. 678.

Removal of Cervical Lymph Nodes.—Heitz and his co-workers assert that treatment of epitheliomas of the mouth or of the upper digestive or respiratory tract should not be aimed at the primary lesion alone but ought to be preceded or followed by treatment of the cervical adenopathies usually also present but not always demonstrated on clinical examination. They consider the surgical technic, the principal characteristics of these adenopathies and the general principles that should guide treatment. The general principles that guide the surgery of cancer in general should be respected in surgery of cancerous adenopathies of the neck region. The two most important rules include, first, the removal of the whole mass *en bloc* and, second, performing a complete intervention. The authors resect the sternocleidomastoid muscle and the internal jugular vein; they consider it indispensable to keep in the muscular planes in all cervical curettages for cancerous adenopathies. The procedure for operation is always directed from the periphery toward the center (the carotid bifurcation). The description of the technic adopted by the authors during the last nine years includes, in order, the following: Incision of the teguments includes one incision that starts at the parotid depression just in front of the mastoid and extends down to the most medial part of the clavicle, half-way between the anterior and posterior borders of the sternocleidomastoid; it crosses very obliquely the direction of that muscle, coming closer to its anterior edge. A second incision starting from the chin is extended to meet the previous incision almost in the center. This incision should be made rapidly, cutting through the skin and the cutaneous muscles at once. This is followed by raising of the strips, low section of the sternocleidomastoid and the internal jugular vein, dissection of the lower carotid region and approaching the carotid bifurcation, submaxillary curettage, removal of the neoplastic mass, and drainage and suture. The authors discuss various methods and modifications and review three personal observations. In bilateral curettage, the second intervention should come from eight to fifteen days after the first. The dangers of bilateral curettage necessitate great caution: one internal jugular vein must always be conserved.

Early Intervention in Knee Sprain.—Leriche does not commend the usual caution which consists in reserving arthrotomy for the functionally grave sequelae. The factors of gravity are always present: The problem consists in knowing how to recognize, early, grave sprains from benign sprains. Grave sprains are those that are due to violent lateral distortion; those in which hemarthrosis returns rapidly after several punctures; those in which the roentgenogram taken after evacuation of the intra-articular fluid reveals a small detached bony fragment, generally at the level of the tibial spine. The author recalls (1929) five other observations besides the one he discusses in this report. In his present observation, a student presented a recurrent hemarthrosis. Intervention the eighth day after the accident resulted in the removal of a fragment as large as a hazelnut, which had become completely detached from the internal border of the patella, and three other small osteocartilaginous fragments in the articular cavity. The patient improved and returned in three months with the knee function normal.

*Dislocation of Foot by External Rotation. M. Boulay.—p. 691.

Vertebral Epiphysitis.—Mocquot and Baumann describe an example of what in the literature is designated as "painful vertebral epiphysitis of adolescence." The patient was a woman, aged 19, who complained of pain in the vertebral column, localized in the lower half of the thoracic region. These pains were sometimes intense, appeared without cause, and were especially exaggerated during fatigue; they awakened the patient with nocturnal paroxysms and were so great in intensity as to render work difficult. Roentgen examination demonstrated a peculiar aspect of the eighth vertebra. In the anterior and inferior portion of the vertebra there was a defect, a loss of substance filled by a small triangular shadow which seemed to complete the vertebral body but was separated from it by a clear space with parallel borders, about 2 mm. wide, directed obliquely down and backward. A. Mouchet diagnosed this as an interesting case of painful kyphosis with persistence in one vertebra of an inferior epiphyseal point of ossification that had remained isolated and had not fused with the rest of the body. This is similar to other dystrophies of the skeleton described as epiphysitis or apophysitis. The pathogenesis is uncertain; there is no proof of an infectious character, although the symptoms are similar to some manifestations in osteomyelitis. The diagnosis of Pott's disease could not be made since there was no definite localization of symptoms and no modification in reflex action.

Dislocation of Foot by External Rotation.—Boulay describes a case in which a man, weighing 82 Kg. (180 pounds), while carying a sack weighing 60 Kg. (132 pounds) down a stairway, twisted his left foot, its anterior face making with the leg an obtuse angle of 120 degrees. Reduction was accomplished easily under general anesthesia and the patient recovered after wearing a plaster-of-paris cast for fifteen days. The foot was doubtless dislocated by a rotation of the body carrying a heavy weight. In a vigorous man, the foot was fixed by muscular contraction and the rest of the body was twisted. The tibiofibular ligaments were certainly torn since there occurred rupture of the internal lateral ligament. The author believes this case to be an example of Huguier's dislocation.

*Basal Metabolism in Pulmonary Tuberculosis. G. Gherardini and G. D'Ignazio.—p. 426.
Clinical Aspects of Cancer of Lung. L. Winternitz.—p. 443.

Changes in Blood After Introduction of Water into the Organism.—Pellegrini, in studying the changes of the blood and of urinary secretion following the introduction of water by the enteral and parenteral route, in normal subjects and in subjects with edemas, observed the following facts: The parenteral introduction of physiologic solution of sodium chloride causes a dilution of the blood proportional to the relation between the quantity of water injected and the mass of the blood. In normal persons such dilution is greatest soon after the injection and decreases gradually and rapidly in from twenty-five to thirty minutes. In edemas due to diseases of the heart, the liver and the kidney, the dilution of the blood so provoked is often greater than is consistent with the quantity of water injected, owing to an afflux of water to the blood from the tissues. The duration of the dilution of the blood in edemas is notably more prolonged than normal and may last from five to six hours. The duration is longest in cases in which the water retention is more grave. With the enteral introduction of water, a dilution of the blood is induced that becomes slowly stabilized and reaches the maximum only after from twenty-five to thirty minutes, remains at the maximum for from twenty to thirty minutes, and then gradually drops down. The maximum attained is generally from 10 to 12 per cent; the total duration of the dilution is about two hours. In edemas the dilution reaches in some cases, owing to an afflux of water from the tissues, higher levels and lasts longer—more than six hours, in some cases. The duration is prolonged in cases with considerable water retention.

Basal Metabolism in Pulmonary Tuberculosis.—Gherardini and D'Ignazio, who investigated the basal metabolism in pulmonary tuberculosis, found it necessary to observe patients over a long period and to make several determinations to avoid the action of intervening factors and considering as habitual a basal exchange occasionally elevated. With this technic they confirmed the existence of increased values in the types with rapid evolution similar to the acute infections. This increase does not exist necessarily in all the forms of tuberculosis, even though they are definitely evolutive. In these cases a prolonged study enables the examiner to note the existence of constant fluctuations, which do not usually exceed the normal limit of error and which denote a peculiar instability of behavior.

Catatonia and Bulbocapnine. B. Spagnoli.—p. 1369.
*Behavior of Blood Catalase in Pneumonia Patients. A. Geremia.—p. 1406.

Behavior of Blood Catalase in Pneumonia Patients.—Geremia studied the behavior of the blood catalase in pneumonia patients during the height of the disease and also during defervescence. He observed an increase of the enzyme during resolution and a diminution in the fatal cases. He advances the hypothesis that the increase during the resolutive period is the expression of the cellular destructive processes through the absorption of the alveolar exudate, and that the diminution in the fatal cases is parallel to the weakening of the vital activity and to the disorganization and alveolar absorption.

Tumor of the Middle and Posterior Cranial Fossae: Case. L. Ferrannini.—p. 860.

Research on Hemoglobin.—Melli and Cantarutti point out that a comparison of the iron and hemoglobin content of the blood and the quantity of oxygen under physiologic and pathologic conditions has shown that there is always a frank parallelism between the color of the hemoglobin and the quantity of oxygen fixed by it. Whereas in normal subjects the iron and hemoglobin values run closely parallel, the parallelism is plainly interrupted in pathologic cases. In pathologic cases it is probable that also in the adult there may be more than one type of hemoglobin; only the assumption of the existence of various hemoglobins of varying iron content will explain the observations made. It is impossible as yet to say anything in regard to the genesis and the significance of these assumed pathologic hemoglobins. Nor is it possible to say whether, under normal conditions, there is but one type of hemoglobin, or whether that which is commonly defined as such is only a mixture in fixed proportions of diverse types of hemoglobin. It is impossible to state definitely whether the variations noted under pathologic conditions are due to the appearance in the circulation of abnormal hemoglobins or simply to an altered quantitative relation between the supposed diverse normal hemoglobins.

Policlinico, Rome

*Pneumotyphoid with Perforation of Pleural Cavity and Pyopneumothorax. V. Chini.—p. 3.
Giant Ovarian Cysts: Case. F. Benso.—p. 15.
*Staining of Microscopic Smears with an Indelible Pencil. F. Marta.—p. 18.

Pneumotyphoid with Perforation of Pleural Cavity and Pyopneumothorax.—Chini reports a case of pneumotyphoid in a woman, aged 55, which was peculiar in its mode of onset, its manifestations and its course. The transition from a state of well being to a state of disease was not sudden, and without any special manifestations or sensations. The patient stated that she thought she had had a slight fever for some time, and after a time began to complain of asthenia and anorexia; she had some attacks of dry cough, but no pain in the chest or "cold," though she had some pain in the limbs, a sense of heaviness in the epigastrium, nausea, and a slight pain in the abdomen. The temperature ranged from 37.5 to 37.8 C. (99.5 to 100 F.). The patient was treated symptomatically without benefit. Although the condition became worse, the patient continued to perform her usual duties as housekeeper. When night came, she was weary, sometimes almost exhausted. So it went on for two months, the temperature gradually rising and the gastric pain and the general fatigue and weakness increasing. Her physician sent her with a general diagnosis of "abdominal disease" to the surgical clinic. The temperature was then ranging from 39.2 to 39.7 C. (102.4 to 102.8 F.). Regarded as a patient with digestive tract involvement, she was subjected to systematic examinations of the digestive organs and their functioning. The examinations were negative, but a fluoroscopic examination of the chest revealed "a left basilar opacity," whereupon the patient was transferred to the general medical clinic. Later, it was found that a typhoid infection existed, not of the ordinary type but what may be called the "ambulatory" type, which enables the patient to continue for some time his usual occupation. But the ambulatory type is not, on that account, to be regarded as mild in comparison with the ordinary types, for, in some respects at least, it is more grave and dangerous. The virulence of the bacillus is not so great, but the disease is equally serious because the typhoid patient, not being recognized as such and not behaving as such, exhausts his physical and humoral resistance, while, at the same time, he is exposed to all the risks of an improper diet and thus to all the complications of that type of disease. This patient was an example of that. The author in this connection recalls a notion of general pathology according to which, for microorganisms not habitually pyogenic, the rule obtains (although not constant) that the pyogenic action corresponds to an attenuation of virulence. The author's patient, having suffered from dry pleurisy at the age of 26 and a left basilar bronchitis at the age of 40, may doubtless have presented in the lung an area of lessened resistance (which was more open to an attack by the circulating bacillus). The patient made a gradual recovery.

Staining of Smears with an Indelible Pencil.—Marta recommends an indelible copying pencil (more particularly, the blue, the violet or the green) for the staining of microscopic smears, as a pencil is always at hand, does not dry out and does not deteriorate as do solutions, and does not soil the hands. The method is simple. With the point of an ordinary copying pencil he places a drop of water on the slide, next to the smear. If the pencil is left in position for a few seconds, the drop of water assumes a sufficiently heavy color, which passes over the smear and stains it instantly.

Surgical Treatment of Deformities Caused by Poliomyelitis. P. del Torto.—p. 1891.
*Calcium Gluconate in Treatment of Gonorrhea and Its Complications. B. Cartia.—p. 1892.

Calcium Gluconate in Treatment of Gonorrhea.—Cartia gave twenty-two patients with gonorrhea or several of its acute complications (acute epididymitis, acute adnexitis, acute cystitis, bilateral arthritis of the knee associated with ostearthritis of the metatarsal region, and total, anterior or chronic urethritis) intravenous injections of from 5 to 10 cc. each of a 10 per cent solution of normal calcium gluconate. The number of injections varied from five to ten, given slowly, either daily or every other day. During the treatment, all general or local medication was discontinued. There were no untoward effects observed, with the exception of a patient who complained of a flushing sensation in his face while he was receiving the injection. In this case, after further dilution of the solution used and slower administration of the injection the redness and heat sensation of the patient's face did not appear again. Clinical and bacteriologic examinations were made in all cases for some time after the treatment was completed. The author concludes that the treatment with calcium gluconate without association with any other drug causes complete disappearance of acute gonococcal adnexitis and epididymitis, the therapeutic results of the treatment being as effective in such cases as those given by gonococcic vaccines or by protein therapy. However, the fact that calcium gluconate does not cause either local or general reactions, as do gonococcic vaccines and protein therapy, makes it preferable. The treatment may be given to ambulatory patients. Calcium gluconate has no therapeutic effect on gonococcal arthritis, cystitis and urethritis. It has, however, an analgesic action on the genital mucous membranes, which is especially favorable in cases of epididymitis and which attenuates the burning sensation during micturition in cases of cystitis or urethritis. It also diminishes the tenesmus and frequent urination coexistent with cystitis. In cases of urethritis, the urethral secretions continued without any clinical or bacteriologic modification both during and after the treatment. The treatment with calcium gluconate is ineffective in acute gonorrheal infections with localization in the genital mucous membranes. Its therapeutic effects on acute adnexitis and epididymitis may be considered as related to a specific chemotherapeutic action of the treatment on these conditions.

Cronica Médica, Valencia

35: 981-1064 (Dec. 15) 1931

*Promising Results of an Obstetric Procedure in Eighty Cases of Shoulder Presentation with Absence of Amniotic Fluid. L. Diaz.—p. 981.
Two New Modes of Palpebral Autoplasty. T. Blanco.—p. 987.
Surgery of Constipation. F. Martin Lagos.—p. 995.
Colorimetric Semimicromethods. J. Morera Arrix and V. Peset Llorca.—p. 1027.

Results of an Obstetric Procedure in Cases of Shoulder Presentation with Absence of Amniotic Fluid.—Diaz discusses the dangers inherent in this class of cases and the impossibility of performing a version without rupture of the uterus. The only alternatives have been cesarean section or embryotomy, and these interventions are not in the province of every practitioner. There remains now a new procedure to provide the uterus with the fluid medium necessary to permit version. This procedure requires a large caliber (number 25 to 29) Nélaton catheter, a 20 cc. glass syringe, a pair of uterine forceps and 1 liter of sterile physiologic solution of sodium chloride. After emptying the bladder and the rectum the patient is anesthetized and the position of the fetus verified. While the left hand steadies the fundus of the uterus, the right hand, holding the catheter between the first and the second finger, is introduced following the ventral aspect of the fetus and the catheter is left in the fundus. Uterine forceps are used to hold the catheter while the hand is pulled out only in case any difficulty is experienced in keeping the catheter in its place. Physiologic solution of sodium chloride is injected, 20 cc. at a time, until 500 cc. has been retained; the position of Trendelenburg may be resorted to, if necessary, to favor retention.

13: 1-12 (Jan. 5) 1931. Partial Index

*Clinical Meaning of Severe Rectal Hemorrhages. R. Pitanga Santos.—p. 2.

Clinical Meaning of Severe Rectal Hemorrhages.—Pitanga Santos states that although small hemorrhages from the rectum are frequent, severe rectal hemorrhages are rare. The characteristics of one type are opposite to those of the other type. Without any previous symptom the patients are taken seriously ill with profuse perspiration, dizziness (which sometimes renders them unconscious), a marked tenesmus and an urgent necessity to defecate. Defecation does not require any effort and the evacuated material consists of large amounts of blood (both fluid blood and coagula). The elimination of massive amounts of blood is repeated at frequent intervals, so that in a few hours the patient's life is in danger if the hemorrhage is not checked. The diagnosis of this type of hemorrhage is easily made: The patient is asked to evacuate so that the rectum is free of any blood during the examination. The examination is made with a proctoscope with the patient placed in the genupectoral position. It is then discovered that the blood spurts from a large vessel ruptured in the center of an ulcer located in or near the ampulla of the rectum. The ideal treatment should be diathermic coagulation. When not available, the vessel should be clamped with a hemostat (of Kocher's type) or galvanocauterized. The author summarizes the clinical histories of four patients who had severe rectal hemorrhages. In two cases a large vessel of the hemorrhoidal venous plexus was ruptured in a chancroid of the anal canal which extended into the rectum; in the other two cases the ulcers, seat of the opened vessels, developed after trauma in one case and from a scar in the other case. None of the patients had cancer or cancerous lesions. The author calls attention to the clinical meaning of severe rectal hemorrhages, which have been considered heretofore as a clinical symptom of cancer of the rectum and which in his opinion should be regarded as a clinical symptom of ulcers of the rectum. His observations on the four patients mentioned, and on sixty-eight cases of cancer of the rectum (sixty in an advanced period and eight at the early period of development), support his opinion. Rectal hemorrhages rarely appear in cancer of the rectum or, if they do appear, they never are of a severe character. Loss of blood from hemorrhoids in patients with cancer of the rectum should not be confused with rectal hemorrhages of a cancerous origin. A clinical symptom of cancer of the rectum is a feeling of pressure of the lower part of the abdomen which appears early in the development of cancer of the rectum and is a constant complaint of the patient throughout the evolution of the disease.

*Roentgen Examination and Lavage of Seminal Vesicles in Chronic Gonorrhea. R. Campos Martin.—p. 539.

Roentgen Examination and Lavage of Seminal Vesicles in Chronic Gonorrhea.—Campos Martin states that when the clinical symptoms indicate the presence of gonococcal infection of the seminal vesicles as a complication of chronic gonorrhea, the roentgen examination of the vesicles is the most important diagnostic method available to ascertain their pathologic condition and whether the infection is unilateral or bilateral. Some other complications of chronic gonorrhea, such as gonococcal arthritis, are secondary to the gonococcal infection of the seminal vesicles and their symptoms are conditioned by the evolution of the seminal vesicle infection. The treatment (whether medical or surgical) of gonococcal infection of the seminal vesicles depends on the patency or obstruction of the vas deferens and of the ejaculatory duct. The author describes in detail the operative technic of lavage of the seminal vesicles with a 5 per cent solution of colloidal silver, to which he resorts as a medical treatment for gonococcal infection of the seminal vesicles whenever the vas deferens and the ejaculatory duct are opened. After having produced local anesthesia of the subcutaneous cellular tissues with a 1 per cent solution of procaine hydrochloride, he makes a longitudinal incision 2 or 3 cm. in length at the root of the testis in order to approach the vas deferens, through which he injects 8 or 10 cc. of the colloidal silver solution into the seminal vesicle, seat of the infection, as previously determined by the roentgen examination. When the roentgen examination shows that the infecion is bilateral, 8 or 10 cc. of the solution is injected into each vesicle. In making the injection, the author uses a common syringe with the finest needle. After having injected the solution, he withdraws the needle and closes the incision with three horsehair sutures. The patient remains in bed for five or six days, during which he receives small doses of opium to prevent any movement of the bowels which may cause a contraction on the seminal vesicles. The retention of the colloidal silver solution in the seminal vesicles during those days acts in a mechanism of complete disinfection of the vesicles. At the seventh day the patient is given a cathartic and under the influence of the contraction of the bowels the colloidal silver is eliminated through the urine. Whenever the patency of the ducts makes possible the *injection of the colloidal silver solution in the pathologic* vesicle (or in both if the infection is bilateral), the symptoms of gonococcal complications such as the pain in gonococcal arthritis, the shreds in the urine, or the gleet, previously present, disappear after the treatment, simultaneously with the improvement of the seminal vesicle symptoms. When the vas deferens and the ejaculatory duct are obstructed, or when the medical treatment fails and the infection of the seminal vesicles is acute, the treatment of gonococcal infection of the seminal vesicles must be surgical. However, the treatment gave good results in the author's cases.

*Suppurative Pericarditis Complicating Bronchopleuropulmonary Diseases. L. E. Vasquez.—p. 6.

Suppurative Pericarditis Complicating Bronchopleuropulmonary Diseases.—Vasquez states that patients with acute diseases of the respiratory tract (pneumonia, bronchopneumonia, empyema) should be subjected as a routine to a careful examination of the heart by which the presence or absence of suppurative pericarditis may be ascertained. Suppurative pericarditis is a frequent complication of bronchopulmonary diseases and develops from a propagation of a pleural effusion during the transitional period from the stage of activity of the disease to the first few days of an apparently normal convalescence. Although the clinical symptoms are almost inconspicuous at the early period of the complication, they are precise enough to make a clinical diagnosis: Rotch's sign, either by itself or in association with Enart's sign, is always present; pericardial friction sounds are audible and dyspnea appears. Later on the pericardial friction sounds disappear, the dulness is generalized over the area of the heart and the dyspnea becomes so intense that the patient takes a characteristic position (the so-called sign of the pillow) frequently observed in patients with pericarditis with effusion. The sign may be described thus: The patient sits at the edge of the bed with a pillow on his lap and reclines his head on the pillow and as soon as he lies down he feels that asphyxia overcomes him. Early clinical diagnosis of this grave complication supported by roentgen diagnosis is of importance because a pericardiotomy is the only hope to save the patient's life. The operation is made with the patient in Fowler's position and with resection of a part of the fifth costal cartilage. After the purulent effusion is evacuated, a drainage tube is left in situ. Dyspnea is the first symptom that improves. The author summarizes the clinical histories of three patients, in two of whom a clinical diagnosis was made. The causative bacteria is the pneumococcus, which may be isolated from the pus of these effusions.

Ventriculoscopy.—For the study of the physiology of the subcortical gray centers and the symptomatology of the cerebral ventricles, Orlando is convinced that reliable results can be obtained only when experiments are conducted under visual control. Ventriculoscopy can be done in patients with congenital hydrocephalus which will allow the introduction and necessary movements of the instrument with a minimum of trauma. The frontal and occipital ventricles and their extensions can be reached from the sagittal line, but the caudate nucleus and the thalamus must be approached through the frontal lobe. Ventriculography is first done to obtain the necessary information on the size, shape and position of the cerebral ventricles and especially of their frontal anterior horns. A point is marked 8 cm. above the superciliary arch and 1.5 cm. from the frontal suture on the side of the ventricle to be explored. A line from this point to the external auditory meatus and a horizontal line through the meatus will form an angle of about 45 degrees. Comparison of this angle with a similar one on the lateral ventriculograms will give exact indications on the direction and angle to be given to the needles and the illuminating instrument in order to penetrate the selected ventricle. With the patient prone, the chin well advanced and secured in order to immobilize the head, trepanation over the marked point is performed, the dura mater incised crosswise and a needle introduced until it reaches the ventricle, when some of the cerebrospinal fluid will escape. A second needle is introduced 3 mm. from the first one: the two needles serve as guides for the ventriculoscope, which in reality is a cystoscope of small caliber. The author describes his first attempt at ventriculoscopy in the living and its unqualified success, and he indicates the practicability of introducing electrodes through the ventriculoscope for experimental purposes.

Endoscopy of Cerebral Ventricles.—Balado points out that, as endoscopy destroys necessarily a certain amount of cerebral tissue, it should be performed through those cortical zones in which loss of tissue is of lesser importance. The endoscope must dispose of an area 1 cm. square in order to move around easily in the ventricles and should consequently be used only in hydrocephalic patients. He describes in detail the anatomic formation of the ventricles and the different structures to be observed. To perform the endoscopy of the occipital and sphenoidal ventricles, he makes a horizontal incision of 6 cm. at two fingerbreadths from the median line and two fingerbreadths above the superior occipital protuberance, trephines at the center of the incision, opens the dura mater crosswise, passes a needle into the ventricle to confirm the presence of hydrocephalus, and chooses the most avascular point for the introduction of the endoscope. He outlines the anatomic landmarks and peculiarities that present themselves to view.

as he advances and turns the endoscope into the ventricle to explore it thoroughly and concludes his article with a review of the indications for endoscopy. These are (1) exploration to find anatomic lesions and to institute their treatment; (2) direct treatment of lesions situated in the ventricle: lesions of the choroid plexus, inflammatory lesions of the ventricle, catheterization of the foramen of Monro, tumors; (3) experiments on anatomic structures by electrical stimulation or extirpation. The author recommends endoscopy as a regular procedure in cerebral exploration provided the size of the ventricles allows its feasibility.

Malariotherapy in Dementia Paralytica Complicated with Diabetes Mellitus.—According to Obarrio and Petre, diabetes is a rare complication of dementia paralytica and is their reason for describing the course followed in treating their patient. This man, aged 39, was given insulin adjusted to a regular stated diet and kept on it until undoubtedly balanced, when malariotherapy was instituted. After six typical malarial attacks, administration of quinine was initiated and during the attacks the patient was put on a milk diet with appropriate doses of insulin. Twice later he was reinoculated with malaria but after three and two attacks, respectively, his temperature returned to normal of its own accord. When discharged, his mental condition was considered satisfactory. The patient was readmitted to the hospital two months later suffering from the results of exaggerated doses of insulin and from renewed mental deterioration. During his second sojourn in the hospital he developed xanthodermia from the carotene pigments of spinach which he was eating twice daily, and duodenal intubation gradually reduced his glycemia. The authors conclude with the following remarks: (1) Association of diabetes with dementia paralytica is extremely rare; (2) diabetes is not a contraindication to the malariotherapy of dementia paralytica provided the necessary precautionary measures are taken; (3) specific treatment given before malariotherapy and subsequent treatment have not modified the diabetes of the patient; (4) xanthodermia was due to carotene pigment of spinach; (5) duodenal intubation has favorably modified the glycemia of the patient.

Intoxication of Pregnancy.—In 1925, Deluca concluded a study of blood groupings with the remark that eclampsia might be due to the fact that mother and child belong to different blood groups. Blood group heredity, similarity of blood grouping in monozygotic twins, and dissimilarity of blood grouping of mother and child in cases of intoxication of pregnancy have been observed by different authors. These authors think that the cause of eclampsia is to be found in the incompatibility between the blood groups of mother and fetus because the red corpuscles of the latter are agglutinated by those of the mother; this presupposes the passage of fetal blood into the maternal circulation through the placenta. Deluca agrees with Lattes and admits by extension a cellular grouping parallel to the blood grouping in which detached chorial cells (fetal albumin) pass into the maternal blood stream and produce the symptoms. Consequently intoxication of pregnancy, including eclampsia, is the result of an incompatibility of the cells of the mother and the fetus and not of their blood.

Jejuno-Ileac Stenosis.—Salvati reviews some of the anatomic peculiarities of the small intestine and their roentgenographic appearance after a barium meal and states that slowly progressive chronic stenosis of the jejuno-ileum presents the following roentgenographic characteristics: 1. Dilatation of the intestinal loops, which may become as wide as and even wider than the colon; if dilatation is found only above the stricture, the caliber becomes considerable. 2. Hydrogaseous appearance of the loops, showing a light upper and an opaque lower part; the loops are of varying shape and situated on different levels which differentiate them from those of the colon. 3. Exaggerated peristalsis. Differential diagnosis: 1. In stenosis of the colon, an opaque enema will be stopped at the constriction while an opaque meal will not be retarded in its passage through the jejuno-ileum. 2. In segmental dilatations of the small intestine, without stenosis, due to chronic mesenteritis, short, uniformly dilated loops will be found mixed up with normal ones, while in stenosis the caliber of the loops increases as they approach the constriction and there is evidence of exaggerated peristalsis. Dilatation of intestinal loops is also encountered in constitutional intestinal atony and in uncompensated cardiac diseases.

Hormone of Posterior Lobe of Hypophysis in Blood of Gravidas.—Anselmino and Hoffmann determined the antidiuretic component of the hormone of the posterior lobe of the hypophysis and the blood pressure increasing substance in the blood of twenty-one gravidas with nephropathy and eclampsia. The demonstration of the antidiuretic substance was possible in nearly all cases with edema. In severe cases the quantity of the antidiuretic substance was larger than in mild cases. From twenty to thirty hours after delivery the antidiuretic substance had generally disappeared from the blood, except in one case of puerperal eclampsia. In the blood of healthy gravidas and of gravidas with dropsy, the antidiuretic substance could not be demonstrated. The authors show that there is a relation between the content of the blood in the antidiuretic substance and the severity of the clinical symptoms, for usually when an improvement was observed there was also a decrease in the antidiuretic substance. The blood pressure increasing substance was demonstrable in all cases in which the blood pressure exceeded 180 mm. of mercury. It was also obs that the antidiuretic component of the hormone of the posterior pituitary and the blood pressure increasing substance may occur in the blood independent of each other.

Neuroma in Uterine Wall.—Kleine observed a true neuroma in the uterine wall of a woman, aged 44, who had had fifteen normal confinements. The size of the tumor exceeded that of an ostrich's egg. Besides a fibromyxochondroplastic sarcoma, the tumor contained a myelinic neuroma free from ganglion cells. The neuroma had undergone necrobiotic changes; it was in the fundus uteri, was covered by the serosa, and was separated from the sarcoma tissue by calcium strands and by myometrium tissue. In spite of the fact that mesodermal mixed tumors are usually highly malignant, the patient was free from relapse and from metastases two years after the operation.

Supernumerary Passages in Uterine Tube. — Kleine shows the significance of supernumerary passages in the uterine tube for the etiology of tubal pregnancy. The histologic studies were made on a gravid and on a nongravid tube. In both of them there were accessory passages between the main lumen and the outer surface of the tube. In the nongravid tube the accessory passage was in the pars isthmica, in the gravid tube the accessory passage reached from the pars isthmica to the proximal portion of the pars ampullaris. Noteworthy was the extensive decidual reaction in the mucous membrane of the passage accessory to the gravid oviduct. Since the abdominal ostium of this tube was closed, the invasion of the ovum must have taken place by way of the accessory passage. The author shows that the development of epithelial passages in the tubal wall is not due to a primary developmental disturbance but is the result of previous endomyosalpingitic disintegration of the sues.

Iodine Content of Blood.—Schittenhelm and Eisler point t that it has been established that administration of iodine fluences the activity of the thyroid. In diseases of the yroid or in those disorders in which the thyroid is considered e causal factor, the iodine metabolism is therefore given reful attention. However, the authors emphasize that it is not necessarily the thyroid alone which regulates the iodine content of the organism; on the contrary, it has been found that the thyroidal hormone is stored in certain portions of the central nervous system, especially in the midbrain-hypophyseal system. The authors tested the iodine content of the blood in patients with exophthalmic goiter and found it increased in all patients who had not received treatment. However, they also observed that the iodine content of the blood may be increased in persons without the signs of exophthalmic goiter; namely, in persons with the signs of vegetative stigmatization. Whether in these persons the increased iodine content of the blood is of central or of sympathetic origin cannot be determined. The authors further report that tests on patients with myxedema and on those with endogenic obesity revealed a reduced iodine content of the blood. They also point out that their former studies on thyroxine and the central nervous system may be helpful in explaining cerebral obesity. They think that in order to decide whether obesity is thyrogenic it is necessary to determine the iodine content of the blood. In all other endocrinous diseases, especially in diseases of the hypophysis, the iodine content of the blood was normal. In the conclusion the authors show that the determination of the iodine content has not only a nosologic significance but also diagnostic value. They consider it more valuable than the determination of the basal metabolism, for the latter only indicates the condition of the organism as a whole, whereas the iodine content of the blood gives information about the intermediary processes. Both tests are helpful in estimating a disease condition; however, the causal genetic factor, the intermediary condition, is, especially for the diagnosis, more important than the general reaction of the organism.

Histologic Evaluation of Uterine Carcinoma for Ray Therapy.—As the first reason why he considers histologic examination of uterine carcinoma necessary, Döderlein gives the verification of the diagnosis. He himself has microscopic preparations of all cases of uterine carcinoma that came under his observation, about 4,000 in all. Thus he can always give the anatomic proof for his diagnosis. The significance of the morphologic diagnosis of cancer has also been stressed by the radiologic commission of the League of Nations. To the objection that the exploratory excision involves certain dangers, the author states that biopsy by means of the diathermic loop eliminates most of the dangers. Histologic examination is also helpful in controlling the effects of the irradiation, and it has shown the necessity of the morphologic differentiation of the various types of cancer. In discussing the different forms of cancer, the author mentions the problem of ray susceptibility. He shows that the opinions about this question differ widely. To make a correct evaluation possible, he considers it necessary that whenever ray susceptibility is discussed the technic of treatment with radioactive substances should be described in detail. To give only the number of milligram hours is not sufficient, for 100 mg. of radium element applied for twenty hours and 20 mg. applied for 100 hours both give a total of 200 milligram hours, yet there is a vast difference between the two. For whereas the first method, when applied with suitable filter and at the right distance, gives good results, the much longer application of the smaller quantity is much less effective and even harmful. For the determination of the cure of cancer the author considers histologic examination as not entirely reliable but stresses that in statistical reports only those cases should be listed as cured in which five years of observation after conclusion of the treatment has proved the absence of cancer symptoms.

Method of Local Anesthesia in Gynecologic Abdominal Operations.—Frigyesi designates his method as the lower abdominal anesthesia. The technic of this new method is almost the same as in hypogastric nerve anesthesia. The only difference is that the 30 cc. of the 0.5 per cent solution of procaine hydrochloride is deposited on the lateral surface not of the fifth but rather of the third lumbar vertebra. After describing the technic in detail the author gives tabular reports of the 112 surgical interventions in which he employed this method; namely, in ventrifixations, in ventrifixations and appendectomies, in adnexotomies, in supravaginal amputations, in total extirpations of the uterus by means of laparotomy, in Wertheim's radical operations, in cesarean sections and in vaginal operations.

Modification of Digestibility of Cow's Milk.—Krane examined the following milk mixtures: milk and water, milk and rice gruel, milk and coffee, milk and barley coffee, milk and black tea, milk and fennel tea, and milk with a 0.5 per cent solution of sodium citrate. In the last series of tests he also examined undiluted milk and a milk-citrate-citric acid solution. The digestibility of the milk mixtures was tested by adding hydrochloric acid pepsin solutions. The author's observations are summed up as follows: If increasing quantities of hydrochloric acid are added to the milk mixtures, the curdled protein changes into an emulsion-like substance. This change does not take place at once in the total quantity of protein, but it increases gradually with the increasing concentration of the added hydrochloric acid until the change is complete. During the change of phases in the dispersion of the milk protein, a binding of free hydrogen ions takes place and it is concluded that the chemical foundation of the process, which appears as the change of phases in the protein dispersion, is the formation of acid albumins. The most suitable diluents of milk are gruel and barley coffee. On the other hand, the digestibility of milk is unfavorably influenced by such additions as coffee and tea. The reduction in the digestibility of milk produced by them is traced to the tannin content of coffee and tea. The assertion that barley coffee is the best diluent has no foundation, since any gruel has the same favorable effect on the digestibility of milk. It is not permissible to base the estimation of the digestibility of a milk mixture merely on the form of the coagulation.

*Gummatous Myocarditis with Adams-Stokes Syndrome and Syphilitic Mesopulmonitis. E. Kux.—p. 1.
*Spontaneous Rupture of Heart. A. Tzankoff.—p. 12.

Gummatous Myocarditis with Adams-Stokes Syndrome and Syphilitic Mesopulmonitis.—Kux observed in a woman, aged 51, who for years had been subject to heart disease, and who had a strongly positive syphilitic reaction, the Adams-Stokes syndrome during a complete auriculoventricular dissociation with about 35 ventricular contractions per minute. The development of an Adams-Stokes attack must be traced at least partly to disturbances of the type of "block in block" since a preautomatic pause was not present, at least not during the attack that was registered on the electrocardiograph. The woman died during an Adams-Stokes attack and the necropsy revealed a gummatous endocarditis of the tricuspid valve, a partly gummatous and partly fibrous myocarditis especially of the right side of the heart, and a gummatous pulmonitis. There also existed a syphilitic mesaortitis with atherosclerosis. Histologic examination of the cardiac septum revealed that gummatous nodules and indurations had led to complete interruption of the common trunk of the bundle of His below the atrioventricular node.

Spontaneous Rupture of Heart.—Tzankoff reports the clinical histories and the results of the necropsies of three cases of spontaneous rupture of the heart. In the first two cases the rupture resulted from a coronary occlusion; in the third case it followed malignant endocarditis and aortic stenosis, the latter causing an increased pressure in the left ventricle. In a general discussion on spontaneous ruptures of the heart, the author maintains that coronary disorders are the most frequent cause. As the rarer causes of spontaneous cardiac ruptures he mentions abscesses or echinococcus cysts of the cardiac wall, syphilitic changes, carcinoma and ulcerations, which originate in the endocardium or in the pericardium, and brown atrophy of the cardiac muscle. In discussing the sites of predilection for spontaneous ruptures he states that it is more frequent in the ventricles than in the auricles, and that it occurs more often in the left ventricle than in the right one. In the left ventricle there are two sites of predilection; namely, the lower third of the anterior wall and the upper third of the posterior wall. The last named localization is much rarer than the first. The symptomatology of the spontaneous ruptures varies. In a small number of cases the premonitory symptoms are slight or entirely absent, and the rupture presents the aspects of an acute heart failure. However, in the majority of cases the patient shows for weeks or even for months the symptoms of angina pectoris. A simultaneously existing increase in temperature indicates an organic origin of the attack of angina pectoris. The author also points out that coronary thrombosis has a typical electrocardiogram, the T deflection being negative and comparatively pointed.

Technic of Microscopic Examination of Vermiform Appendix. H. Junghanns.—p. 35.

New Approach to Hypogastric Plexus.—In the introduction, Vorschütz discusses the innervation of the pelvic viscera and shows that it is controlled mainly by the hypogastric plexus. By anesthetization of this plexus, pains in the pelvic organs can be counteracted, and for this reason many gynecologists conclude their operations with an injection into the region of the promontory. However, if the abdominal cavity has not been opened, it is comparatively difficult to reach the plexus. The author reviews the methods of different authorities and then describes his own procedure. He approaches the plexus from below, by way of the colon. After the colon has been thoroughly cleaned the patient lies on the left side, the legs flexed on the thighs and thighs flexed on the abdomen. The approach is by way of the incisura ischiadica. Following anesthetization of the point of puncture a nickel-plated steel needle, 14 cm. in length, is introduced between the os sacrum and the coccyx, 6.5 cm. to the right of the median line, so that it points toward the promontory. At a depth of 12 cm. the promontory is reached. When the needle point has reached the bone, it is retracted from 1 to 2 mm., and then the injection is made and the fluid spreads in all directions, also upward to the aortic plexus. In this manner all the nerves in this region are anesthetized. The author made this injection particularly in women with backache when pathologic changes were not detectable in the pelvic organs. In these usually neurotic patients, the pains could be overcome at least temporarily. However, for surgical purposes the author did not resort to this injection of the hypogastric plexus. He further discusses the anesthetization of the solar ganglion in painful conditions following extirpation of the gallbladder, and also in certain gastric pains. But since the injection effects only temporary anesthesia it is not satisfactory in painful conditions of long duration, such as tuberculosis of the bladder, or in inoperable cancers. In such cases only the permanent exclusion is effective, and the author discusses the advisability of extirpation of the plexus, citing the opinion of different authors. He concludes that temporary as well as permanent anesthesia can be produced without impairing the function of the bladder, the colon or the generative apparatus.

Unusual Aspect of Calcification in Thoracic Cavity.—Hubrich reports the case of a woman, aged 43, who was subjected to a roentgen examination prior to a goiter operation. During this examination a dense shadow was observed in the left upper portion of the thorax. Roentgenologic examination of the lung revealed that the calcification was not merely a surface and belonged neither to the anterior nor to the posterior pleura, but that it had a more spatial character and was surrounded by pulmonary tissue. The anamnesis revealed that, twenty-four years before, the woman had fallen from a ladder and after that had felt piercing pains in the left side of the chest. At that time the woman had been hospitalized for six weeks, but definite information was not obtainable about the character of the exudate at that time. The author assumes that the pulmonary injury had caused a hematoma, which led to destruction and necrosis of the pulmonary parenchyma and later to calcification. For the differentiation of this form of calcification from calcifications of pleural indurations it should be considered that, whereas the pleural calcifications appear as surfaces, the others have a more spatial character.

Specific Treatment of Chronic Gonorrhea in Women by Means of Soluble Gonococcal Toxin. K. Retzlaff.—p. 58.

Entrance into Pelvis of Fetal Head.—Gauss calls attenion to what he terms the "entrance effect," that is, to that hase of labor when the head of the child, after having stood or some time above the pelvic inlet, suddenly, as with a jerk, nters the pelvis. This process involves dangers for the child, specially in case of a narrow pelvis, and during this period he control of the fetal heart sounds is of greatest significance. 'he author mentions the following signs as indicating that the hild is in danger: prolapse of the umbilical cord, constant liminution of the fetal heart beats to less than 100 per minute r their constant increase to more than 160, marked fluctuaions of more than 40 beats, great irregularity of the heart ounds, and discharge of meconium. On the basis of his obserations he considers it advisable to hasten the process of delivry by employing forceps whenever the fetal heart sounds ppear disturbed for some time after the fetal head has entered he pelvis. In the last part of the article he discusses the auses of the entrance effect. He is not certain whether the great pressure at the pelvic inlet or the sudden decrease in pressure after entrance into the pelvis or perhaps both factors are responsible for it, but he emphasizes the necessity of special watchfulness during this phase of birth.

Ulcerations on Portio Vaginalis as Sign of Disease of Blood.—Habbe describes the clinical history of a woman, aged 32, who during recent months had become weak and had lost in weight. She then became ill with high fever, hemorrhages of the oral mucous membrane, and ulcerations on the nose and upper lip. The physician in charge diagnosed a pneumonia and because of genital hemorrhages he thought of septic abortion and sent the woman to the clinic. The author describes the results of the general examination on admission to the clinic. Gynecologic examination revealed on the portio vaginalis bleeding and disintegrating tissue, resembling carcinoma, but the biopsy revealed that there was no tumor, but that instead of the surface covering there was only necrotic tissue. The concurrence of this necrotic process with the ulcerations on the mouth and nose and with the pneumonic process was now considered as indicative of a serious generalized disease and agranulocytosis was thought of. The examination of the blood corroborated the assumption of the existence of a disease of the blood; however, it was found that not only the leukopoiesis but also the erythropoiesis was seriously impaired. The diagnosis of septic abortion proved erroneous, for the genital hemorrhages were caused only by the ulcerations on the portio vaginalis. In the conclusion the author expresses the opinion that the ulcerative processes on the skin and mucous membranes and especially those on the portio vaginalis were symptoms of a severe generalized impairment of the hematopoietic system.

Pathogenesis and Immunity in Infections of Air Passages (Influenza, Pneumonia). K. Lewkowicz.—p. 21.
*Experimental Smallpox Vaccination. Anna Eljasz.—p. 26.
Clinical Value and Nature of Davis Reaction. S. Brückner.—p. 30.
*Clinical Study of Hemorrhagic Diathesis (Hemophilia). A. Landau and W. Hejman.—p. 32.

Experimental Smallpox Vaccination.—Eljasz, in the macroscopic and microscopic study of changes produced by the smallpox virus in animals, found that the guinea-pig is the animal of choice for experimentation. Simultaneous epidermal and intradermal application greatly hastens the course of the disease. Histologic changes are recorded daily until all the symptoms disappear. The changes are those of simple allergy. The epidermal method produces symptoms similar to those found in human beings but the course is shorter; the intradermal method is followed by negligible changes and no degeneration of the epidermis. Both methods produce allergy.

Clinical Study of Hemorrhagic Diathesis (Hemophilia).—Landau and Hejman divide hemophilia into three distinct forms: (1) the form due to reduced coagulability, (2) the form due to reduced blood platelet count, and (3) the form due to capillary changes. The first class includes all cases of hepatic origin: icterus, tumors of the liver and biliary passages, inflammatory conditions of the bile ducts and pancreas, atrophy, and syphilitic and hypertrophic cirrhosis. The platelet type makes its appearance usually when the platelet count falls below 30,000 per cubic millimeter, regardless of the type of the primary disease. Hemophilia due to capillary changes (Henoch-Schönlein) was observed in chronic endocarditis and kidney diseases when uric acid reached above 3 Gm. per thousand cubic centimeters of blood. The authors introduce a classification of hemophilia into apparent and concealed forms. This is motivated by the fact that frequently far advanced changes do not give hemorrhagic symptoms while others with insignificant deviations from normal are marked by severe hemorrhages. The class that is attended most by hemorrhages is the vascular type, and the other two classes become apparent after the vascular system becomes impaired. The symptoms of hemophilia are in direct relation to the degree of relaxation and dilatation of capillaries.

*Inguinal Herniotomy: Two Hundred and Thirty-Six Herniotomies Without Transplantation of Cord with After-Examination of Two Hundred and Twenty-Four Cases, Together with Remarks on Methods of Herniotomy and Results of These. J. M. Wollesen.—p. 527.

Inguinal Herniotomy.—Wollesen's statistical survey of late results after the most usual methods of herniotomy, as published in the world literature, shows the average number of relapses in indirect hernia to be 5 per cent; in direct, 15 per cent. After-examination in his 224 cases showed permanent results in 98 per cent. His method without transplantation of the cord, a combination of several methods, is applicable, he says, only in indirect hernia. The treatment of the sac and the closure of the abdominal opening are of especial importance. According to the literature those methods are most likely to give permanent results which do not disturb the muscular function of the inguinal canal and which call for suture of fascia to fascia and muscle to muscle. In direct hernia the method of choice is a plastic operation of the rectus which avoids (1) weakening the function of the abdominal muscles, (2) sewing muscle to fascia, and (3) the danger of producing a femoral hernia by traction on Poupart's ligament. Bilateral hernia should apparently not be operated on in one sitting.
